COMPLETELY FURNISH THE LABORATORIES OF SOUTH ASIA'S LARGEST RESEARCH CENTRE!

"A remarkable achievement in design, consultancy and co-ordination".

All over the world, Baird & Tatlock have designed and executed laboratory installations of every type and size Their service includes expert advice at planning stage, design and manufacture of special units and, for some projects, on-site supervision of installation.

For the giant CIBA Research Centre at Goregaon, India, BTL were called in to furnish the entire 80 laboratories—totalling 36,000 sq ft of floor space!

Wherever you are planning extensions or complete new laboratories, call in the BTL Furnishing Division. This is the first step to speedy and successful completion of any laboratory project.

BAIRD & TATLOCK

TENS OF THOUSANDS...

We are not suggesting that this amount of research has gone specifically into these two latest 'SPEEDIVAC' rotary pumps, but many years of continuous vacuum investigation and development of vacuum pumps has lead up to their standard production Special features include, carefully designed lubricating systems which ensure silent and vibration-free running . . . patented control valves which prevent suck-back when the pump stops . . sealed cases for gas-recirculation and recovery work. . the ED500 has a patented oil-recirculation system which permits only degassed oil to enter the high vacuum stage.

'SPEEDIVAC' ES35
Ultimate vacuum without gas-ballast, better than 0.01 torr; with gas-ballast, better than 0.5 torr Compressor rating (continuous) 20 lb/in² (1.4 kg/cm²) Speed 35 l/min (1.24 ft³/min).

'SPEEDIVAC' ED500
Ultimate vacuum without gas-ballast, better than 0.0001 torr, with gas-ballast, better than 0.005 torr. Speed 500 l/min (17.7 ft³/min).

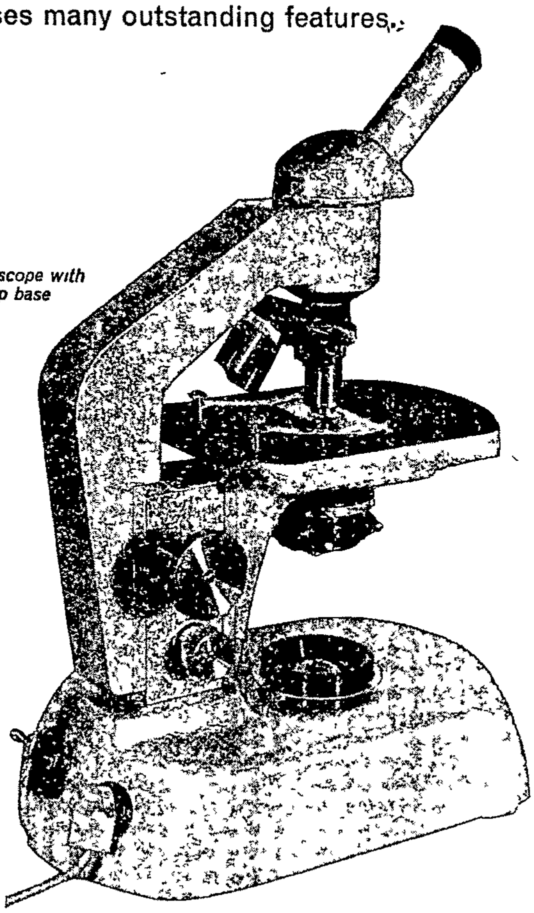
NEW FROM

WATSON

The SERVICE 3 Microscope

In basic form, the new Watson Service 3 Microscope is a reliable, robust and easy-to-use instrument for student biological microscopy. With accessories it is fully capable of satisfying many of the demands of advanced workers. Up-to-date in appearance and design, it possesses many outstanding features.

A Watson quality microscope designed to meet changing needs from student use to advanced graduate studies



Service 3 Microscope with low-voltage lamp base

* choice of inclined monocular head, inclined monocular head with drawtube, or inclined binocular head All units can be rotated through 360° and are quickly interchangeable A vertical monocular head is also available

* rotating quadruple nosepiece accepting the full range of Watson high-performance sleeve-mounted objectives

* spring-loaded 4 mm and 2 mm parachromatic objectives.

* all objectives parcentred, parfocalled and colour-coded for easy identification.

* large acid-resisting plain stage accepts Watson attachable mechanical stages

* focusing condenser assembly for pre-centred or centring mounts each fitted with iris diaphragm and filter holder.

* low-placed coarse and fine adjustment controls.

* choice of three bases mirror assembly, concealed 25 w mains voltage lamp and condensing lens, concealed built-in low voltage lamp (6 v 18 w), light control unit and condensing lens.

* new durable 'everclean' finish.

An extensive range of Watson optical and mechanical accessories can be used with the *new* **SERVICE 3**

If you would like to know more about this outstanding new instrument, please write for full details to

SHANDON

UNIVERSAL Electrophoresis Apparatus after Kohn Mk.II for all electrophoresis techniques

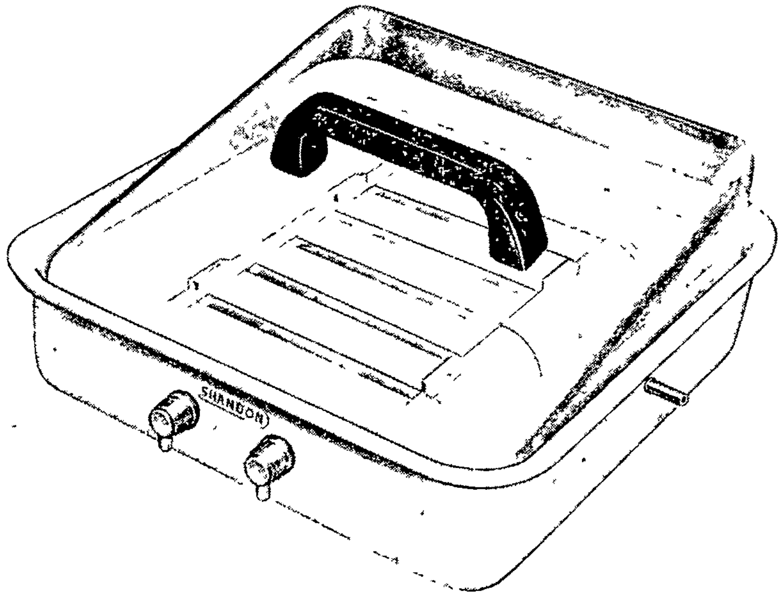

Fig. 1
Kohn tank with six 2.5 cm wide cellulose acetate strips

The versatile Shandon UNIVERSAL Electrophoresis Apparatus, Mk. II (Fig. 1), consists of a one-piece moulded Perspex tank, double-walled to allow the circulation of water or other coolant. The inclined transparent Perspex lid forms a draught- and vapour-proof seal with the water jacket. The bridge gap is adjustable from 8 cm to 16 cm wide.

The apparatus is ideal for use with cellulose acetate strips, starch, agar gel, or filter paper, and a full range of accessories can be supplied. The Shandon Vokam Constant Voltage/Constant Current Power Supply is specially recommended for use with the Kohn Tank.

Shandon's latest developments now make it possible to use the advanced micro-immunoelectrophoresis technique as a routine analytical method. Shandon micro-immunoelectrophoresis accessories for the UNIVERSAL Electrophoresis Tank will fit *any* electrophoresis apparatus with electrode compartments at least 9¼ inches long. Fig. 2 shows the Kohn Tank and Lid, with Slide Tray, Gel Contact Troughs and Vokam Power Supply.

INTERACTION OF SCIENCE AND THE STATE

SELDOM, if ever, can two major addresses at a British Association meeting have directed such pointed attention to the address of an earlier President as was done at Aberdeen Sir Eric Ashby's tribute (see *Nature*, 199, 877, 1963) to his predecessor was forthright and generous enough, yet a few nights later Prof R V Jones built his evening discourse on "Science and the State" (see *Nature*, 200, 7, 1963) largely around the presidential address which Lyon Playfair delivered when the Association met at Aberdeen in 1885—quoting incidentally the passage from the presidential address of the Prince Consort at the first meeting of the Association in Aberdeen in 1859, which Playfair took as his own text Prof Jones displays the range and versatility of Playfair's interests and mind, recalling that it was pointed out to the Government at a conference on the neglect of science in May 1916 that in the whole history of British Governments there had been only one Cabinet Minister who was a trained professional man of science—Lord Playfair

Appropriate as was this tribute to Lord Playfair at this year's Aberdeen meeting, it is equally welcome for its relevance to the present-day debate on the relations between Government and science, and the announcement of Prof Jones's return to the Ministry of Defence for some months, made shortly before his lecture, added interest to his remarks Prof Jones regrets that, in the address over which he runs his critical eye, Lyon Playfair makes no reference either to the relations between science and the Services or to the general question of wisely making and implementing scientific policy These subjects apart, Prof Jones's survey of Lyon Playfair's address demonstrates not merely the impressive range of his interest but the prescience and pertinence even to-day of many of Playfair's comments. Over science and education, the responsibilities of Government for the schools, the balance between classical and scientific studies in the curriculum, the place of science in the universities, the relations between the universities and other research establishments, between science and industry, and the critical importance of fundamental research, Playfair ranged with a vision far ahead of his contemporaries Prof Jones, bringing the historical survey up to date, remarks justly how many mistakes might have been avoided had Playfair's advice been taken

What makes Prof Jones's lecture one of the major events of the Aberdeen meeting is, however, essentially his discussion of the two topics which Playfair omitted, but to that discussion his review of earlier relations between Government institutions and research establishments is entirely relevant Welcoming the recent report of a working party of the Federation of British Industries on *Civil Research Policy* (see *Nature*, 199, 725, 1963), with its awareness of the need for more co-ordinated support of scientific research in the universities, Government establishments, the research associations and industry generally, Prof Jones puts a reasoned argument for such co-ordination Broadly speaking, his argument is an extension in general terms of that advanced regarding physics departments in the universities in the recent report of the committee appointed by the Council of the Institute of Physics and the Physical Society, of which he was chairman (see p 200 of this issue of *Nature*)

Prof Jones stresses the effect on the balance of our research effort to-day of the redistribution of that effort during the Second World War, particularly in any field such as physics in which the supply of scientists is insufficient to meet the demand It was, he points out, a pure accident, though a consequence of the foresight which led Britain to recruit scientists to Government establishments in support of air defence just in time that, whereas in the United States the universities, in which much of the war research effort was necessarily concentrated, increased considerably in strength compared with the Government establishments, the reverse happened in Britain We have yet to take sufficient account of the consequences of a separation of Government establishments from the universities and the creation of conditions which greatly restrict the interchange of staff Moreover, this is quite apart from the fact that Government establishments are now often able to offer not only higher salaries, better equipment and more generous technical assistance than the universities can do, but also the prospect of giving more time to actual research, including fundamental research

Prof Jones recognizes that this position applies more especially to physics in view of its greater involvement with matters of national defence during the past thirty years, but he points out that Britain's smaller resources make it essential for her to be even more careful than the United States in husbanding her scientific potential, both for teaching and for research. It is just as important to realize the teaching potential locked up in the Government establishments as it is to realize the research potential of the universities, and of the colleges of technology also Nor is it a simple matter to secure the most efficient use of Britain's most precious resource—highly trained scientific manpower—even in industry, let alone the universities It is a problem to be tackled not piecemeal but on a national basis, and Prof Jones regards the securing of a better balance between universities and Government establishments and between these and the requirements of industry, the technical colleges and the schools as one of the most important problems confronting both science and the State in modern Britain

Some awareness of the implications of this situation was shown two years ago in the Zuckerman Report, *The Management and Control of Research and Development* (see *Nature*, 193, 710, 1962) However, although Government departments have been reported to be implementing that Committee's recommendations, the results as regards interchange of staff or location of establishments do not as yet appear to have been appreciable For a decade or more, too, the educational potentialities of the research associations have been emphasized in these columns, but so far with little, if any, effect Prof Jones, none the less, sees this as an urgent and critical problem in the expansion of higher education itself as well as in the more effective deployment of Britain's research effort it is to be hoped that neither the Robbins Committee nor the Trend Committee will fail to report clearly and emphatically on the issue

It is from this issue that Prof Jones comes to consider specifically the question of science in the defence effort, and here he welcomes the changes in organization proposed in the recent White Paper on the *Central Organization for Defence* (see *Nature*, 199, 1021, 1963) These changes, he thinks, will prevent the scientific staff attached to the central Chiefs of Staff organization, with no executive duties, from being overburdened by administration, and hence enable it to devote its whole time to the study of the influence of advancing knowledge on the problems of defence—conditions such as were advocated by Sir Henry Tizard in his lecture to the Royal United Services Institution in 1946 Prof Jones believes that the new arrangement increases the strength of the Chief Scientific Adviser, placing him on the Defence Council alongside the Chiefs of Staff of the three Services, and that it is a wise arrangement for those three Services to keep enough of their individualities and traditions to preserve the loyalties which have contributed so much in emergencies to their fighting spirit The merging at the higher levels he regards as assisting national and economic planning, and he also regards science and technology as a main factor in unifying the Defence Services and lowering the barriers between them

Beyond this, Prof Jones makes no reference to the administrative structure or to any relation between the Defence Research Committee and the Advisory Council for Scientific Policy Nor does he refer to the position of the Minister for Science, though he quotes with approval a suggestion made by Colonel Alexander Strange in a lecture to the Royal United Services Institution as long ago as 1871 for a Minister of Science, responsible for all scientific national institutions, and advised by a permanent, independent and highly qualified consultative body and a similar body to advise the Secretary of State for War and the First Lord of the Admiralty He does not comment on Lord Hailsham's recent book, *Science and Politics* (see *Nature*, 198, 1123, 1963), but some criticism of Lord Hailsham's position is implicit in the lecture

Generally, Prof Jones would appear to be satisfied with an organization which ensures the communication of scientific advice effectively at the highest level, as Lord Louis Mountbatten described in his remarks at the 1962 anniversary dinner of the Royal Society. None the less, he does suggest that all is not well with Britain's national organization of science, nor would it appear that he is entirely satisfied with some of the research arrangements contemplated in the new Defence organization Some rationalization is needed, and Britain is in danger of repeating the German error of allowing individual centres to become just too strong and independent for coherent organization and economic direction

It is here that he insists on the need for strong leadership from the Ministry for Science, and he clearly does not share Lord Hailsham's reluctance for central planning and leadership Nor is he unduly concerned that great responsibility must rest on a relatively small number of men This he regards as inevitable, and he points out that, especially in defence matters, executive decisions have often been taken by individuals He would use the committee system where possible, remembering, however, that decisions taken by a Committee are sometimes less sensible than those which any of its individual members would have reached The important thing is that science should be so organized that some of Britain's best men of science are in key-administrative positions in Government so that policy decisions affecting science are not taken by non-scientific men, whose judgment is at the best based on how individual scientists have convinced them

Prof Jones is confident that Britain is still great enough to produce men of the right calibre, and here he agrees with Sir Charles Snow as to the danger of isolation His own solution is to provide a small forum for each of the principal scientific advisers to the Government Each forum would consist in the main of scientists, as nearly as possible the adviser's equal, so chosen that the membership covers the full range of his activities, and including some relatively young men to ensure that the necessary energy, imagination and working contact with the most modern technology are available If the adviser were as wise as he should be he would consult the forum before taking any decision, and while the responsibility would remain his alone, he would take his decision only after having heard the relevant arguments Moreover, he would be able to justify it in any subsequent encounter with his forum

Prof Jones believes that such a forum would provide the only sanctions needed to prevent the individual from abusing his power, beyond those already set by Britain's form of Parliamentary Government—and his suggestion is based on experience with it in a limited field during the Second World War It certainly appears to offer the possibility of avoiding some of those errors of judgment, at least in the scientific and technical field, which Prof Brian Chapman has so strongly indicted in his recent book, *British Government Observed**, and which he rightly insists we can no longer afford The suggested forum has in any event, superficial resemblance to the "cabinet" or "private office" with which, Prof Chapman suggests ministers should be provided to assist forward planning What is curious, however, is that, in the context in which he writes, Prof Chapman gives no attention to this question of the injection of scientific consideration into matters of State, neglect of which might well be the determining factor in the loss of prestige and influence by Britain

This blind spot is the more surprising in that Prof Chapman in his glance at the French administrative system and the recruitment of civil servants, notes with approval the care taken to avoid creating mere technical experts and to provide, on the contrary, men of unassailable technical competence who have also throughout their careers been learning the art, techniques and discipline of general administration Moreover, with this recruitment to high administrative office of men of widely different backgrounds and general administrative experience, Prof Chapman also stresses the deliberate use in European ministries of the cabinet system of a minister's private office, in which the policy-making function is concentrated, as a forcing ground for younger men of talent By such means, European countries have, he believes, created for themselves a reserve of administrative talent unknown to the higher British Civil Service

Prof Chapman makes three main criticisms of Britain's present system and practice of Government, but before considering these and their implications the importance of the mechanism of tendering scientific and technical advice and the stage at which it is injected should again be emphasized While there are undoubted weaknesses in the present structure, there is little evidence to show that the systems in vogue in Europe or in the United States offer any substantial advantage over that of Britain, if it is properly used and staffed The National Centre for Scientific Research in France, which is the chief body responsible for basic research there, is attached to the Ministry of Education and is responsible for the analysis of scientific development for the Government, and the Minister of Education is a member of the Inter-departmental Committee of Scientific Research, of which the Prime Minister is chairman This Committee of Ministers is advised by a Consultative Committee on Scientific and Technological Research, but it is not easy to see from the report on scientific and technological research under the Fourth Plan 1962–65, published in the current issue of *Minerva* (1, No 4, 1963), or from the annual reports of the National Centre, what inherent advantage this system offers over Britain's, if the Office of the Minister for Science were reasonably strengthened and some rearrangements made

---

* *British Government Observed Some European Reflections* By Brian Chapman Pp 64 (London George Allen and Unwin, Ltd, 1963) 12*s* 6*d*

Nor does Dr A Hunter Dupree's article in the same issue, "Central Scientific Organization in the United States Government", suggest that Britain has much to gain by adopting the tripartite structure evolved in the Office of the President The Advisory Council for Scientific Policy obviously serves many of the functions of the President's Science Advisory Committee, though Britain has yet nothing quite corresponding to the Federal Council of Science and Technology, and any analogy between the Special Assistant to the President for Science and the Minister for Science could be misleading Dr Dupree, who does not appear to share Prof Jones's view that the American universities emerged stronger from the War, looks to this structure to be effective in making choices between fields correcting the inherent and valuable pluralism of science itself The essence of his review is that every State must achieve for itself a balance between central unity and this essential plurality, which is in harmony with its own traditions and its own institutions He insists that the scientific community itself has to give serious thought to the protection of the institutions through which science manifests its plurality At the same time, because decisions concerning priorities in science have to be made on behalf of the general community, there is also necessary a central scientific organization, aware of the social and political impact of science, and capable of assisting the authorities of the whole community in making such decisions about the organization of research.

Nor is this view of what is essential invalidated either by an article by Prof D Auger on "Scientific Co-operation in Western Europe", which appeared alongside Dr Dupree's article, or by the even more recent report, *Science and the Policies of Governments* *, from the Advisory Group on Science Policy of the Organization for Economic Co-operation and Development While Prof Auger sees some need for further systematization in the scientific and technical fields, he advances no criticism of the national structures which form the basis for international co-operation These seem to be sufficiently harmonious to facilitate and not to hinder scientific work

Likewise the report on the implications of science and technology for national and international affairs recognizes that any policy developments at international level must be firmly based on the right relations between science and policy making at the national level Its arguments for the establishment by all Governments of what is described as a 'science and policy office' and the duties which it suggests for such are familiar to all who have followed the debates in Britain on the functions of the Minister for Science, but it will be noted that they refer particularly to the need for adequate research in the social sciences and the humanities

If there is no convincing evidence in all this that there is anything seriously amiss with Britain's existing structure, though some that could in various ways be modified and improved, the real indictment is exactly that which has been brought against Britain's overseas broadcasting services—that the organization is not sufficiently used and adequately supported It is a question of Government will-power

This question of will-power brings us to the heart of Prof Chapman's main criticisms First, he believes that Britain's loss of prestige and failure to deal adequately with the problems of the modern State are due to failure to revise archaic procedures and to reform the institutions for making policy Next, he believes that this is accentuated by Britain's failure to recruit talent to the work of Government at all levels, from Ministers and Members of Parliament to the higher ranks of the Civil Service and to local government Thirdly, the consequences of all this is the worse because of secrecy which surrounds so much of the work of Government, and particularly the making of policy, so that effective public discussion before decisions are taken and mistakes are made is almost impossible

Prof Chapman recognizes that this last is not solely a question of secrecy but also of the quality of information, much of which falls short of the standard which should be used in British Government The factual material on which policy is based is sometimes bad and sometimes non-existent Although the Plowden Report (see *Nature*, 192, 485, 1961) pointed in the right direction, much more use could be made of the techniques of operational research and computers to provide the data on which decisions should be based and to enable these decisions to be reached much more swiftly.

That issue could be joined with Prof Chapman, and some minor points should not prevent those scientists who are concerned to see that scientific factors receive full weight in the making of policy and taking of decisions from encouraging such a marriage. Prof Jones's proposal of a forum for the scientific advisers is in keeping with Prof Chapman's emphasis on the importance of informed and authoritative discussion. The proposal to open up the top of the Administrative Class of the Civil Service to outside recruitment is scarcely new, but Prof Chapman's recommendations would carry the process a good bit further. The tardiness with which the much more limited recommendations in that direction of the Plowden Report and the Zuckerman Report have been implemented point to a lack of zeal or will-power on the part of the Government The practice and structure of Government may now be receiving more attention than Prof Chapman seems inclined to admit, although he welcomes some of the proposals of the Plowden Committee for reform of the Treasury as likely to improve the quality of the Treasury's contribution to central Government To secure attention in these fields on the scale and with the urgency required, and still more to effect the reforms he suggests in the efficiency of Parliament itself, the creation of strong regional centres of Government or the revision of the laws of official secrecy will require much informed discussion and the creation of a strong body of public opinion To the creation of that opinion, Prof Chapman's little book makes a contribution which may be all the more valuable in that it is timed to inform the discussion in due course of both the reports of the Robbins Committee and of the Trend Committee

HIGHER EDUCATION IN PHYSICS

DURING the past few years a spate of reports and letters bewailing the difficulties of academic scientists has reached the journals and the newspaper Press. Although many different views have been expressed, their sheer number shows that there are urgent problems which must be tackled. Two years ago the Institute of Physics and the Physical Society established a committee, under the chairmanship of Prof. R. V. Jones, to study problems facing university physics departments, especially those affecting their growth. This committee submitted some striking evidence to the Robbins Committee on Higher Education in 1962 (see *Nature*, 193, 922, 1962) and has now completed its work.

The final report* deals with a wide range of problems, and the conclusions are well supported by detailed arguments based on data drawn from many sources, including a special enquiry among all university physics departments. Although some of the problems are specific to physics, this report should be closely studied by all scientists and those responsible for the administration of scientific work.

Certain conclusions are clearly of the greatest importance. For example, the physicists are unanimous in their view that there must be active research work, both pure and applied, within all university physics departments, "in order (*a*) to attract physicists of calibre adequate to carry out teaching, and (*b*) to transfuse this teaching with the inspiration of the living and exciting subject that physics is". University research is seriously hampered to-day by lack of skilled technical help and, frequently, by lack of funds for equipment and travel. If the expansion of student numbers, which the Government desires, is to be achieved, then this report makes a convincing case for increased support for research.

At the present time a great deal of basic physics research in Britain, both pure and applied, is carried on in Government research laboratories. Unfortunately, very little of this, often excellent, work benefits either undergraduate or postgraduate education. This is not the case in the United States, where, during the Second World War, the Administration farmed out to research teams in universities problems that would have been tackled by Government establishments in Britain. This difference in approach has had a lasting effect in both countries, but it is now urgent that some way should be found for gradually changing the pattern of Government spending on research in Britain. A larger fraction than at present must be directed to the support of university research.

If the universities are active centres for research and if the research workers can obtain reasonable financial support for projects, which are blessed by their fellow scientists, then it should be possible to recruit the teaching staffs required to implement the Government's target of 150,000 full-time students in universities by 1966–67. To achieve this total, up to 40 per cent of the Ph.D. output must be attracted to the profession of university teacher. As already argued, this requires adequate funds for research, much more technical help than at present and undoubtedly some improvement in the present salary structure.

Despite the 1963 revision of the quinquennial grant (1962–67), it is clear that the University Grants Committee has failed to persuade the Treasury to give the universities an adequate growth-rate for the annual grants. For example, during the 1957–62 quinquennium student numbers increased by 4.5 per cent per annum. This growth was achieved with financial grants increasing at 12 per cent per annum, and there is evidence that standards, such as the staff/student ratio, have declined slightly. The Government plan for the present quinquennium calls for a student growth of 6.2 per cent per annum, but the financial grant grows only at 11 per cent per annum. To quote the report again "if the final numbers are achieved, it will only be at the expense of the staff/student ratio and basic support for research". This must not be allowed to happen. Britain needs to increase opportunities for higher education, but all concerned must be prepared to pay the proper price.

The Office of the Minister for Science should give close attention to this report, and it is to be hoped that the Government will take urgent measures to improve the situation. The long-awaited reports of the Robbins Committee and the Trend Committee on the organization of civil science ought to deal effectively with many of the more serious problems raised by the physicists.

---

BEARING OF MODERN RESEARCH ON EVOLUTION

Evolution

The Modern Synthesis. By Sir Julian Huxley. Second edition with a New Introduction. Pp. li + 652. (London: George Allen and Unwin, Ltd., 1963.) 42*s*. net.

A CLASSIC is defined as a work that defies the passage of time and preserves its intrinsic value and interest, even when the conditions under which it was conceived are no longer the same as those in which it continues to be appreciated. This is the secret underlying the work of Leonardo, Shakespeare, or Brahms, and it means that although a classic may be dated it is not out-dated. In the humanities, works of art are created by human genius and remain as they were although standards of criticism applied to them improve. In the natural sciences, however, although an outstanding analysis or synthesis may be likened to a work of art, it is immersed in a constantly moving stream of progress represented by advances in knowledge in every direction. The great experiments devised and performed by pioneers in science, the discoveries resulting from them and, to some extent, the publications in which they were described, remain to be admired for all time, although possibly now read more often by historians of science than by practising scientists, but text-books or attempts to provide round-ups of the state of science at any given time for the benefit of students wither into obsolescence and fall into disservice at increasing rates as the *tempo* of successful scientific advance increases.

A special position is occupied by Darwin's *Origin of Species*, sometimes regarded as a fine monument of Victorian achievement that some scientists, in the enthusiasm of their pursuit of new lines of research, would be prepared to leave to the historians. This would be a pity, because that extraordinary book, for all the progress that evolutionary studies have made in the past hundred years, continues to provide not only a fundamental framework in which to interpret all phenomena of biology but also general principles on which new programmes for observation and experiment can profitably be based, and, in addition, can still suggest unsuspected new fields for such activities, so wide was the observational catchment-basin and so sound the judgment and uncanny dumb sagacity of its astonishing author

It is against this background and, to a large extent, this heritage that we must consider the uncommon phenomenon of the re-issue, in its original and unaltered text, of a twenty-year-old text-book devoted precisely to this field in which such spectacular advances have been made during these same twenty years Sir Julian Huxley's *Evolution The Modern Synthesis*, which may be regarded as companion, commentary and extension of the *Origin of Species* When it was first published in 1942 the time was appropriate, for the author had (but only recently) had the benefit of the epoch-making integration of the principles of Darwinian selection with those of Mendelian genetics, largely due to the insight and ability of the late Sir Ronald Fisher, whose great *Genetical Theory of Natural Selection* had been published only a few years previously, in 1930 From that time on, the chaos and confusion into which evolutionary studies had fallen in the earlier decades of this century (still detectable in works that refer to the modern theory of evolution as 'mutationist') were dispelled and removed, and the way opened for co-ordinated research by observation and experiment on evolution in every field of biology This great opportunity was brilliantly seized by Sir Julian with the result that his book became the first general text-book to deal authoritatively and comprehensively with the new situation created by the formulation of the synthetic theory of evolution, to show the general principles to be derived from it and therefore to provide the student and the research-worker with an indispensable chart and compass The remarkable thing is that now, in 1963, the same chart and the same compass are no less useful than they were twenty years ago. The book is a classic, and it is to be welcomed that the author and his publisher decided to leave the body of the text just as it was, and to prefix an introduction of 37 pages directing attention to the more important results achieved during the past twenty years Even new principles, such as those of genetic assimilation or allotypy, fall into place

To review such a book, in detail, a second time would be uncalled for (see previous review, *Nature*, 150, 747, 1942), nor is there any need to comment on the selection of new work included in the introduction except to say that it is a remarkable achievement I shall merely add that, although it has been known since 1859 that evolution by natural selection was a unifying concept for all biology, it is only now becoming clear how all-embracing it is, and how closely it knits together the numerous and ever-increasing branches and experimental disciplines of biology The synthetic theory of evolution has also enhanced and raised the scientific status of certain branches of natural history For example, ornithology has been recognized since the days of Gilbert White as a most respected field for amateurs Ornithology, in the form of the birds of the Galapagos Islands, supplied Darwin with the stimulus to question the fixity of species Ornithology revealed the principle of territory and its significance in bird life, worked out by Eliot Howard, and the biology of epigamic characters, courtship and display in birds was the subject of some of Sir Julian's own early researches Paradoxically, the *Origin of Species*, itself the product of pioneer work in the field, sent biologists indoors into their laboratories for half a century, working out the comparative anatomy, embryology, and palæontology of the representatives of the various evolutionary trees, all indispensable work Now, biologists have gone out into the field again, having remembered that Darwin himself was the founding father of ecology, a movement in which Sir Julian has played a leading part During these recent times, ornithology has made giant strides, in species identification, behaviour studies, analysis of bird-song and the modalities of its learning, control of reproductive rate and clutch-size in relation to ecological and climatic conditions, polymorphism not only of adults but also of eggs combined with mimicry in cuckoos and its genetic control, census and measurement of population size, geographical races and spread of range, climes and ecological 'rules', species-formation in ring-species where it can be observed actually in progress, migration and its relation to ecological and hormonal factors, homing and orientation in flight in relation to meteorological and astronomical factors, the application of biochemical technique to egg-albumens as indicators of affinity, and the principle of mosaic evolution as revealed by that most remarkable of fossils, *Archaeopteryx*

Studies in the field can now be accompanied and controlled by exact analysis in the laboratory, which can lead to novel situations, as, for example, the fact that modern techniques have made the sounds of bird-songs more susceptible to exact analysis than visual observation of form, colour and pattern, previously regarded as the chief aids to species-identification All this co-ordination of points of view and cross-fertilization of effort, due primarily to the concept of evolution by natural selection, is an integrative achievement of which biology may well be proud, and physicists perhaps envious This book is the best guide to it GAVIN DE BEER

THE ROWETT INSTITUTE

Progress in Nutrition and Allied Sciences

Being a contribution marking the first fifty years of the Rowett Research Institute Edited by D P Cuthbertson Pp xvii+452 (Edinburgh and London Oliver and Boyd, 1963) 50*s*

IN the fifty years of its growth the Rowett Institute has had two directors The first was John Boyd Orr, who started it from nothing and tended it for 33 years before handing it over to David Cuthbertson, who has achieved the great expansion of its activities recorded in this Jubilee volume of progress It is fitting that the Golden Jubilee Year of the Rowett Institute should be the occasion of the sixth International Congress of Nutrition which is being held in Edinburgh with Lord Boyd Orr as its honorary president and Dr D P Cuthbertson as its president

It is enlightening in this day of costly buildings and equipment to read of the terms of the appointment of Boyd Orr in 1913 to a post for research in animal nutrition from a Joint Committee of the University of Aberdeen and the North of Scotland College of Agriculture, and of his early presentation to that Committee of plans for a much larger project than their ideas and funds originally permitted Although the First World War interrupted the plans, the idea of establishing a Nutrition Research Institute was encouraged from Government and private sources The largest private aid came from Mr John Quiller Rowett, whose name the Institute commemorates The new building was opened by H M Queen Mary in the autumn of 1922 Then the research work begun in the small stone building at the farm at Craibstone could expand and the flow of distinguished workers already associated with the Institute could increase

The history of the Rowett Institute from 1913 until 1945 is lovingly sketched by Lord Boyd Orr in the opening chapter, and its all-too-brief pages indicate how the unflagging pursuit of a vision by a man of courage and persuasive charm can build up a research foundation able to contribute much for the welfare of mankind In this history is included a short account of the setting up of the Imperial Bureau for Nutrition and of the beginning of the journal *Nutrition Abstracts and Reviews* which carries information on animal and human nutrition to all parts of the world. More information on the growth and expansion of the Bureau, now the Commonwealth Bureau of Animal Nutrition, is given by Dr Isabella Leitch in her later chapter on the subject This side of the work of the Rowett Institute owes much to the wide appreciation of human needs by the first director, and it is in itself a great contribution to research and education in nutrition

The development of world nutrition programmes through the Food and Agriculture Organization of the United Nations had its origin in the nutrition work of the League of Nations inspired through the co-operation of the Rt Hon Stanley Bruce, High Commissioner in London for Australia, and Boyd Orr, who could see that the progress of the world depended on the "marriage of health and agriculture" The implementation of the programme begun in Geneva in 1935 led on to the idea of the World Food Board and to the Food and Agriculture Organization The appointment of Sir John Boyd Orr (as he was then) as first director-general of the Food and Agriculture Organization indicated how highly his work for international nutrition was valued The origins and early development of the Organization are recounted by David Lubbock in a lively chapter reflecting his intimate knowledge of this phase of the outward growth of the Rowett Institute.

The new director, who took over the sadly depleted staff and resources of the Institute in 1945, tells the tale of progress during his own time The very great expansion of activities is further demonstrated by the chapters from many present and recent past members of the staff who give specialized accounts of their own fields of research There are now Departments of Applied Nutrition with sub-divisions of Nutrition, Biochemistry and Metabolic Experiments, of Biometrics, of Protein and Lipid Chemistry, of Enzymology, of Microbiology, of Physiology, of Pathology with Helminthology, as well as the Duthie Experimental Stock Farm and the Commonwealth Bureau of Animal Nutrition The head of every one of these diverse disciplines is an expert in his field, and the staffs attached to the departments are clearly producing useful and interesting work as shown by their research papers

It is impossible to comment on all the individual contributions, but the chapter from R L M Synge, a Nobel Prizewinner for his work on partition chromatography, on "Some Nutritional Aspects of the Non-protein Nitrogen Fraction of Plants" is particularly salutary as it puts into perspective the chemical studies of foodstuffs made in the past half-century. Synge is severely critical of many studies on non-protein nitrogen fractions in cabbage and other vegetables and warns nutritional scientists of the dangers of being unaware of the wide assortment of new substances being isolated from foodstuffs by their chemical colleagues One of the problems he uses as an example is the nature of the goitrogenic substance occurring in cabbage

Many of the chapters are concerned with ruminant nutrition and physiology, but pigs and poultry are not neglected nor are the needs of man forgotten Chapters on "Family Diet and Health in Pre-war Britain" and "Studies of Human Growth" show that the Institute is a centre for work on the nutrition and health of the population not only of Britain but also of other countries The whole volume is rounded off by a chapter from Dr Cuthbertson on "The World Food Situation as Related to Knowledge of Science and its Application"

Lord Woolton in his foreword makes a plea for the simplification of scientific language, especially in reports on matters of nutrition, so that unscientific members of the community may read and understand advances in nutritional knowledge Lord Boyd Orr has always had the gift of simple exposition in telling phrase and has tried to impart his ability to those who worked with him The share that his colleagues and their successors have taken in educating the world in nutrition is amply demonstrated in this Jubilee volume

There are a few errors which have escaped the eagle eye of the editor. The most curious is the caption under the frontispiece where Her Majesty Queen Mary is called Her Royal Highness This no doubt will be quickly corrected Others are probably sheer slips in proof reading and it is perhaps unfair to complain of small blemishes on so fine a publication The illustrations of guests at Founders' Dinners, of the Staff in 1951, of the aerial view of the Institute and, best of all, of John Boyd Orr at Craibstone in 1919, are a delightful accompaniment to the essays from past and present staff members. It is good to have the short biographical notes on past staff members who have contributed to the volume

THE WELLCOME HISTORICAL MEDICAL LIBRARY

Catalogue of Printed Books in the Wellcome Historical Medical Library

Vol 1 Books printed before 1641 Pp xv + 407 (London The Wellcome Historical Medical Library, 1962) 210*s* , 30 dollars

Catalogue of Western Manuscripts on Medicine and Science in the Wellcome Historical Medical Library

By S A J Moorat Vol. 1: MSS written before 1650 Pp viii + 697 (London The Wellcome Historical Medical Library, 1962) 210*s* , 30 dollars

THE decision to publish the catalogues of the important medical and scientific collections in the Wellcome Historical Medical Library was taken while Sir Henry Dale was chairman of the Wellcome Trustees It is therefore appropriate that he should—at the invitation of his successor, Lord Piercy—introduce the first-fruits of this great project to the public and tell us something of the scope and character of what is indeed a very unusual library and one of the most interesting charitable bequests of our time

The Wellcome Library was first opened to the public in December 1949, and its extraordinary resources have been made freely available to students and research workers in all fields of learning and from all countries throughout the whole of the period during which these catalogues have been in preparation and in the press The first indication of the range and importance of its collections was given to the outside world by the *Catalogue of Incunabula* (Oxford University Press, 1954), which was the work of its present chief librarian, Dr F. N L Poynter He has also been responsible for the first volume of the Library's *General Catalogue of Printed Books,* which lists all books in the Library printed before 1641, some 7,000 items which include the *editiones principes* and subsequent Renaissance editions of Galen and Hippocrates, a most comprehensive collection of the first editions of Paracelsus, fine copies of great medical landmarks such as Vesalius and Harvey, as well as those for general science such as Galileo and Kepler The second series of this catalogue, covering works published between 1641 and 1850, will occupy four or five volumes and will reveal equal riches for two centuries of unprecedented scientific development, Boyle, Newton, and Lavoisier being represented by first editions of their works alongside those of Malpighi, Lower, Sydenham, Morgagni, Hunter, and Jenner

These treasures have been brought together over the past sixty-five years, the collection built up by the late Sir Henry Wellcome (1853–1936) and his assistants having been expanded with judgment and learning by subsequent librarians Among these was Mr. S A J Moorat, a graduate of Merton, and librarian during 1931–46, a period when the library was still strictly private and generally unknown He is now keeper of Western Manuscripts in the Library, and to him we are indebted for the first volume of a catalogue which describes all the manuscripts written before 1650 Among the 1,500 items contained in 800 volumes (representing only 15 per cent of the collection of Western MSS) are many of the first importance to the history of science and medicine Although concise details of collation, script, etc , are included, Mr Moorat's main object has been to give information on the authorship and subject-matter of these writings The descriptions of individual manuscripts are supplemented by no less than 11 indexes which open these treasures to every aspect of scholarly research

In these two volumes there is a wealth of material for those seeking to show how modern scientific thought emerged from the blend of classical tradition and semi-religious scholasticism that characterized the Middle Ages, and we must be grateful to all who have been concerned in producing what must be widely regarded as a massive contribution to the history of civilization

K J Franklin

RADIOISOTOPES IN BIOLOGY AND MEDICINE

Use of Radioisotopes in Animal Biology and the Medical Sciences

Vol 1. (Proceedings of a Conference held in Mexico City, 21 November – 1 December, 1961) Pp xvi + 563 (London and New York Academic Press, 1962. Published for the International Atomic Energy Agency) 115*s*

VOLUME 1 of *Use of Radioisotopes in Animal Biology and the Medical Sciences* is the first part of the proceedings of an International Atomic Energy Agency Conference held at Mexico City in November 1961. Many conference proceedings are now being published under titles such as this that conceal their true nature, presumably to encourage sales to library committees

Artificial radioactive isotopes have now been in widespread use in biology and medicine for fifteen years, and international and national conferences on their uses have been frequent during this time. In the early years they were very useful, one thinks, for example, of the well-organized meetings in Oxford in 1951 and 1954 The huge United Nations Geneva conferences in 1955 and 1958 were successively less valuable The many isotopes available and the methods available for their use were becoming well known Papers began to be concerned more with investigations and experiments with diverse and valuable results, but in which the use of isotopes was really only a useful incidental, comparable with the use of, say, the microscope, the paper chromatogram or the flame-photometer

The 1961 Mexico City conference was apparently organized because "although the fields (of human and veterinary medicine) use the same tools, the same training and techniques, and often the same experimental animals, opportunities for the exchange of information between the two fields are all too rare" The papers given, however, cover a wide range of subjects and are by no means confined to veterinary medicine, and only in the very loosest sense to animal biology Most of the contributors come from North and South America, with a small number from Europe

There are four introductory review papers by J H Lawrence, D H Copp, A A Kudryatsev and R. F. Glasscock on the use of isotopes in, respectively, medicine, physiology, veterinary medicine and biochemistry Kudryatsev's paper is in Russian and is a review of entirely Soviet work with 64 references, the subsequent discussion is in English As in other fields, there is much work done on the central nervous system, and on conditioned reflexes in particular It is suggested that the weight of farm animals might be raised by small doses of external radiation The other three papers are extremely good and interesting reviews, but confined in turn to work in the English language

The main body of the volume consists of thirty-five papers classified as relating to general physiology, hæmatology and glandular function There are abstracts in English, French, Russian and Spanish and discussions in English

Space will not allow mention of more than a few individual papers In the first general section there is a variety of interesting subjects There is first a paper from Oak Ridge showing many superb autoradiographs of Protozoa incorporating tritiated cytidine, uridine and thymidine There are papers on different aspects of intestinal absorption One of these is on the unfamiliar metabolism of tin in sheep, studied because of the use of tin in a fungicide used on plants such as turnips and mangolds fed to sheep and cows Workers from Chicago gave a valuable paper on the water spaces of the brain as studied by sulphur-35 and carbon-14-labelled compounds, contrasting with results from Moscow outlined in the succeeding discussion There is a similar contrast between papers from Israel and France investigating spermatogenesis by phosphorus-32 in man and animals, respectively.

The third section, headed "Glandular Functions", consists of ten papers on radioiodine and thyroid function and one on the effect of progestogens on the genital tract of guinea pigs as shown by sulphur-35 autoradiography. There are two interesting reports on endemic goitre in the Philippines and Venezuela; it is suggested that there is a genetic basis for endemic goitre and that there may be a relative increase in the proportion of plasma triiodothyronine compared with thyroxine in goitrous patients

This kind of publication can be useful in directing attention to unfamiliar work which will only be published elsewhere in foreign journals not necessarily available in accessible local libraries This particular volume is very well edited and produced and has a limited 'skeleton index' It can be recommended, in spite of earlier remarks regarding its title, to libraries of veterinary science and animal physiology

THE BRICKS OF MATTER

Atomic Physics Today

By Prof Otto R Frisch Pp vi + 254 + 18 plates (Edinburgh and London Oliver and Boyd, Ltd , New York Basic Books, Inc , 1962) 25*s*

ATOMIC PHYSICS TODAY is based on a number of individual broadcast talks and articles written by Prof Frisch during the past few years These have been revised to bring them into line with present-day knowledge, but it is pleasant to note that the original brightness and spontaneity have been retained, in addition to the self-contained character of each of the sixteen chapters The reader can, with equal satisfaction and profit, either dip into the volume and read any one of the chapters separately or proceed steadily through the book as a whole. The topics discussed cover a wide range They deal not only with the well-established phenomena of nuclear fission, fusion, radioactivity and elementary particles, but also with the rather abstruse and more difficult concepts and theories relating to waves and particles, quanta, nuclear structure, the neutrino, parity, the individuality and origin of particles of matter, and causality

The descriptions given by Prof Frisch are all clearly, simply and lucidly expressed. Nevertheless one is fully conscious that they are exact, authoritative and penetrating The recent developments in nuclear physics which he discusses are those in which he himself has taken an active interest and to many of which he has made important contributions The fascinating way in which he not only outlines the discoveries and observations but also lays bare the underlying fundamental problems is greatly to be admired His enthusiasm very often leads him beyond this, and he does not hesitate to state categorically, where he considers that theory is lagging sadly behind experiment, where new lines of thinking need to be followed, and where there are many puzzles still remaining to be answered Prof Frisch affirms that fission, though it has given mankind the possibility of enormous amounts of power, is conceptually no great discovery The discovery that parity is not conserved is much more important, maybe not technologically, but certainly intellectually To try to find out why this occurs and how it fits into the material framework in which we live is just one of the many examples representative of the delight and pleasure in the search for and the acquisition of new knowledge, which, Prof Frisch concludes, is the driving force which compels him and his physicist colleagues to undertake often arduous and tedious experimental and theoretical research work

Atomic Physics Today should be read by both physicists and other scientists, and also by the adult layman It presents not only an excellent picture of modern physical knowledge, but also serves an important present need for directing attention to the compelling curiosity that urges a man to become a scientist, and on the devotion and enthusiasm with which research work is carried out in our universities and research establishments

S WEINTROUB

A COOKERY BOOK FOR CARBOHYDRATES

Methods in Carbohydrate Chemistry

Edited by Roy Whistler and M L Wolfrom Vol 1 Analysis and Preparation of Sugars. Pp xxii+589 143*s*. Vol 2 Reactions of Carbohydrates Pp xv+572 139*s* 6*d* Vol 3: Cellulose Pp xvi+407 110*s* 6*d* (New York and London Academic Press, 1962–63)

SINCE all cookery books contain sugar recipes it was inevitable that we should have eventually a cookery book for sugars themselves Here we are presented with three volumes out of a projected five or more of a new series which the editors term the "methodologies" required in dealing with carbohydrates

The field of carbohydrates is broadening at an enormous rate, especially on the biological side and, even more important, in regard to industrial applications The editors felt that the time had come when some help must be given to the non-specialists who needed many of the more unusual sugars or their derivatives Accordingly they have secured the ready collaboration of a wide company of the world's leading carbohydrate chemists, who themselves are familiar with the methods or indeed who initiated the techniques

In Volume 1 is described the methods of preparation and analysis of many of the simple monosaccharides There is a preliminary section on carbohydrate laboratory techniques, describing methods of purification, crystallization, etc , and the important and rapidly developing application of gas-liquid partition chromatography to sugar derivatives Important directions too are given for chromatography on paper, extrusion column chromatography, cellulose column chromatography, zone electrophoresis, and carbon column chromatography These are methods which have made an enormous difference to the separation of closely related sugars and their derivatives, and the non-expert and student will be most grateful to have this widely scattered information set down in such a concise manner by the experts Precise descriptions are given in later work for the preparation of 'exotic' sugars such as erythrose, threose, lyxose, ribose, altrose, tagatose, and so on It would seem impossible to go wrong with such precise directions provided Sometimes, however, one is a little disappointed, for example, in the section headed "Streptose", one finds on reading that this is still only a hypothetical substance and only its derivatives can be obtained by the methods provided An excellent description is provided for the labelling of some sugar derivatives and this work could well have been made more extensive A very large and most valuable section is provided on the analysis of sugars, thus the determination of reducing sugars by a wide variety of methods is given in a precise manner, quantitative aspects of chromatography are shown and the determination by means of enzymatic methods and by isotopic analysis Methods of periodic oxidation, often a complex and tantalizing business, are described with great clarity Nothing is left out, not even the relatively indeterminant colour reactions about which Dische has written with great authority The physical methods of measurement of properties, including X-ray, infra-red and diffraction, are also given in great detail Volume 1 is thus of high importance to all chemists and biochemists interested in sugars

Volume 2 deals with the methods involved in the preparation of derivatives of monosaccharides together with a few oligosaccharide compounds Major authorities in the field have again been appealed to and many valuable points of technique, not necessarily published before, are provided The standard pattern of an introductory paragraph, followed by the procedure and the valuable references, is followed A very large amount of information is given on the sugar phosphates which are indeed among the most difficult of organic compounds Valuable methods for the provision of methyl ethers of mono- and di-saccharides, which for a long time represented the most important series of key compounds in the whole of carbohydrate chemistry, are provided There are some omissions such as those of the methods of Kuhn The degradation of sugars, especially the polysaccharides, by means of alkali is becoming of increasing importance, so that the section on the preparation of saccharinic acids will be very valuable for the industrial chemist in particular Extensive information is provided on thiosugars, on isotopic carbon distribution and on products obtained by oxidation and reduction methods in the sugar field

In Volume 3, written almost entirely by industrial chemists, we are given essentially a new book on cellulose Already there are many volumes on this subject, but here we have, written down for the first time, more precise conditions for the most important aspects in the field The isolation of pure cellulose from a variety of sources is concisely described and, following this, methods are given for the chemical analysis of cellulose Up-to-date information is provided on the wide range of physical methods for the analysis of cellulose As workers in the field will know, the assay of crystallinity is of immense importance, and this is particularly adequately described Methods for the degradation of cellulose together with the products identified are also covered in a valuable way

There are some omissions, particularly in the modern work on cross-linking, which is becoming of great importance In all the volumes the methods are given with such detail and precision that they can readily be repeated The extensive cross-references are extremely valuable Some authors unfortunately still use outmoded methods of writing down formulæ

This publication, although expensive, can be very strongly recommended for all chemists and for all libraries

M STACEY

Language, Meaning and Persons

By Prof Nikunja Vihari Banerjee Pp 173 (London· George Allen and Unwin, Ltd , 1963) 30*s*

THIS book, the work of an Indian professor, is a continuation of his earlier *Concerning Human Understanding*, and embodies a serious attempt to present a cure for what, in his view, is the prevailing sickness of philosophy Whether he will find agreement that his patient is ill, or even, if so, that his prescription will be effective or even desirable, is another matter

It would appear that philosophy needs liberation, and this means in particular that it should extricate itself from its subservience to science and logic Which done, it could then apply itself wholly to mankind and the needs of the individual, making him unexceptionally a member of society, inseparable from his fellows Included in this would be a revival of metaphysics

Naturally, such an outlook must reckon with religion sooner or later, and the way in which this encounter occurs is peculiar The problem is faced sympathetically, but a supra-mundane being is considered incapable of dealing with the evils and perplexities of a technological age and the self-directed cravings of men One may well ask how else can humanity be saved if it is forbidden to look outside itself

The discussion includes the epistemological background, imagination, language, meaning and persons, ending with the question of human liberation Incidentally, the writer has the slightly tiresome habit of saying 'generally', when he almost certainly means 'usually'

But this slender volume is provocative in the good sense, and has a healthy reaction against the tendency of philosophy to be a poser of problems and no more

F I G RAWLINS

The Pathology of the Tumours of Children

(Pathological Monographs, No 2) By Prof Rupert A Willis Pp vii+200 (Edinburgh and London Oliver and Boyd, 1962.) 42*s*

TUMOURS of children are a special problem in pathology It is not to be expected that environmental factors, such as are well known to be responsible for cancer in adults, can be the cause of neoplasms in infancy For an explanation of these we must turn to embryology and to someone who is an acknowedged expert in both embryology and pathology Prof Rupert A Willis is obviously the man A few years ago he began a former book entitled *The Borderland of Embryology and Pathology* with this sentence "Almost from the beginning of my work in pathology, the embryological aspects had a special appeal for me, and I felt sure that embryologists and pathologists had much to gain by a better knowledge of each other's subject" This earlier book (published by Butterworth in 1958) has already become a classic and the best guide to the understanding of malformations and errors of development It has paved the way for the latest book by Prof Willis, entitled *The Pathology of the Tumours of Children*

As with all his other books, this is based on personal experience Its nucleus has been a personal histological collection of more than 700 tumours from children A special feature is that cases cited in the text can be identified by a code of initials, and duplicate histological sections and records of all specified cases have been incorporated in the Imperial Cancer Research Fund's Tumour Reference Collection This will be much appreciated, because the histological classification of some tumours of children is difficult for hospital pathologists without special experience In this field even experts often disagree Many instances of differences of opinion are admitted in this book, one typical example being from the "gliomas of uncertain nature" where, in one instance (case 6, p 35), the panel of experts differed greatly in their diagnosis

The value of a monograph such as this depends on three features (1) the authority of the author, (2) the choice of references to other work, (3) the quality of its illustrations In this work, as in all his previous writings, there is no doubt about the authority of the author or the selection of references Moreover, in this latest book, all will agree also that the illustrations are superb They are the work of Mr E V Willmott, of the Imperial Cancer Research Fund

C E DUKES

The Identification of Molecular Spectra

By Dr R W B Pearse and Prof A G Gaydon Third edition Pp xi+347 (London Chapman and Hall, Ltd , 1963) 120*s* net

SINCE this book was first published in 1941—and particularly in the thirteen years since the second edition appeared—advances in the development of spectroscopic techniques and a widening of the fields of research in which spectroscopy plays a dominant part have led to the publication of a vast amount of new data With the same care and precision as marked the previous editions, the authors have collected and collated the data up to the end of 1961 The table of persistent band heads, extending from p 3–50, includes some 350 new entries and is set out with extreme clarity and ease of consultation The bulk of the book (pp 51–320) deals with individual band systems, including 84 molecules not previously included and 135 molecules for which additional or revised data have been obtained In some ten pages are given practical procedure and precautions, followed by a number of actual spectra and an appendix of the persistent atomic lines of each element

The authors are to be warmly congratulated for their assiduity and patience in sorting out and presenting in such an eminently acceptable form information which will prove to be of incalculable worth to all who are directly or indirectly concerned with molecular spectroscopy.

The printing and general arrangement are excellent and make it so easy to use the book For what it contains —and is—this book is good value at £6

W ROGIE ANGUS

The Earth and You

A Geographic Picture of the World We Live In By Dr. Norman J G Pounds Pp 591 (London John Murray, 1963) 50*s* net

THIS is a general account of the way in which climate, soil and mineral resources have affected the life of man It is especially welcome at a time when the growth of the Earth's population and the problem of increasing food production concern all thoughtful people Dr Pounds makes it clear that geographical factors cannot alone explain differences in living standards, he contrasts areas of comparable climate and resources and does not hesitate to point a moral where necessary

He first discusses the Earth as a whole, its structure and climate, criteria of over- and under-population, gross national product, food consumption and the factors which link men in political units There follows an account of the principal regions of the world and the States composing them The reader is made conscious of the difficulties that arise when social, economic or political aims conflict with facts of topography or climate

The book makes interesting reading, is well produced and is illustrated with many diagrams The two-page maps would have been better mounted to 'fold-in' some of the main points of interest are obscured by the fold of the binding

So wide a survey cannot be detailed, but Dr Pounds has provided a supplementary reading list for those who wish to make a more detailed study of a particular area They are nearly all American publications The book will be a welcome addition to a school library or to the possessions of any person who seeks information on matters of general interest

RESEARCH, INNOVATION AND ECONOMIC GROWTH*

By K. PAVITT†

Directorate for Scientific Affairs of the Organization for
Economic Co-operation and Development, Paris

Economic Growth and the Role of the Organization for Economic Co-operation and Development

ECONOMIC growth means an increasing provision of goods and services to satisfy individual and collective human wants. In the past 150 years, certain areas of the world have seen a steady and substantial growth of production per head of these goods and services, in general accompanied by a steady growth in population. This growth has generally gone hand-in-hand with a more equitable distribution of wealth among the population, more opportunities for education and more leisure.

The Organization for Economic Co-operation and Development is an inter-Governmental organization consisting of twenty member-countries from North America, Western Europe and the Mediterranean region. Its aim is to promote economic growth among its members, and to co-ordinate their aid to the economically less-developed countries. A large part of the work of the Organization is therefore concerned with conventional economic and aid policies.

However, the member-Governments of the O.E.C.D. are becoming increasingly concerned about their national efforts in scientific research and development, largely because many Governments are paying increasingly large sums to support research and development, but also because of a general and rather vague feeling that an adequate national effort in research and development is now essential in an industrial society. This concern has led to the creation in many countries of governmental bodies concerned with the national research and development effort. Belgium now has a National Council for Scientific Policy, France, a General Delegation for Scientific and Technical Research, the United Kingdom, an Office of the Minister for Science, and the United States, a President's Office for Science and Technology. Within the past year the Italian, Swedish and West German Governments have established special departments or councils to deal with questions of scientific policy.

Scientific Discovery and Innovation in Economic Growth

The work of the Directorate for Scientific Affairs of the O.E.C.D. has therefore become largely concerned with the contributions which scientific and engineering education, and scientific research and development, make towards economic growth, and with the governmental policies required to ensure that these contributions be effective. This article will briefly set down some of the important problems which have so far been raised by this work.

It must be stressed from the outset, however, that an adequate level of research and development, and rapid innovation, are not the only conditions necessary for economic growth. For the purposes of this article, it will be assumed that the other conditions, such as a stable political system, stable means of exchange of goods and services, an adequate level of demand for these goods and services, and a system ensuring equitable rewards for productive effort and efficiency, already exist.

To say that scientific discovery and innovation are important factors in increasing the productivity of labour is to say nothing new. In the eighteenth century, Adam Smith wrote of "The invention of a great number of machines which facilitate and abridge labour, and enable one man to do the work of many"[1]; and about the sources of invention he wrote that "All improvements in machinery, however, have by no means been the inventions of those who have had occasion to use the machines. Many improvements have been made by the ingenuity of the makers of the machines, when to make them became the business of a peculiar trade, and some by that of those who are called philosophers or men of speculation, whose trade is not to do anything, but to observe everything, and who, upon that account, are often capable of combining together the powers of the most distant and dissimilar objects"[2].

Much more recently, Prof. S. Kuznets gave six lectures on the nature of economic growth since the time when Adam Smith was writing, and concluded that the sustained increases in the productivity of labour could not have been maintained without continuous innovation, that is, the new application of either old or new knowledge to production processes. Since the possible uses of old knowledge were limited, continuous innovation required continuous new additions to knowledge. He went on to point out that many of the industries now important in the advanced economies, for example, in the electrical, chemical and internal combustion fields, were entirely unknown a hundred years ago[3].

As Prof. Kuznets implies, and as Adam Smith dimly foresaw, innovation in the industrially advanced countries has become increasingly dependent on discoveries made by trained scientists and engineers, and on the regular and systematic exploitation of such discoveries in the economy. There is evidence in many countries that the proportion of the total number of patents taken out by trained scientists and engineers is growing. Also, the resources in the economy devoted to 'research and development activity'[4] are growing in most of the industrially advanced countries[5].

One can suggest that the following factors are influencing this trend. First, entrepreneurs have seen from past experience that innovation based on scientific discovery can be profitable, and the widening boundaries of science have given them more and increasingly powerful tools with which to manipulate their physical environment, and to create and improve products and production processes. Secondly, the increasing scale of industrial operations has made it organizationally more efficient for innovational activity—namely, research and development—to be undertaken as a separate, but related, entity. Thirdly, the nature of production processes is increasingly such that persons working in production cannot so easily make any startling innovation or routine improvement; the outside of a length of chemical piping must surely frustrate any would-be inventor. Fourthly, certain companies are using techniques which are at the limits of scientific and technical knowledge, so that improvement and change can come only by finding new knowledge as a result of research and development. Finally, it must be admitted that certain companies undertake research and development because it is fashionable, and with no clear idea of its potential economic usefulness

---

* Substance of a paper read before Section F (Economics) of the British Association meeting in Aberdeen on September 3.

† The opinions expressed here are those of the author and not necessarily those of the O.E.C.D. I thank Dr. A. King and Mr. J. R. Gass for their comments and suggestions.

What, then, can statistics tell us of the extent to which technological innovation, and research and development on which it largely depends, have influenced rates of economic growth? (It must be borne in mind that these statistics can measure neither the benefits which research and development bring in the form of improved goods for consumption at constant prices, nor of the improved welfare of the population resulting, say, from medical research)

The importance of innovation has been confirmed by a series of investigations undertaken in the United States which show that only about one-half of the growth of labour productivity over the past 50 years in the United States can be explained by the growth in the amount of capital per man, and by the improved allocation of both labour and capital[6] The remaining growth must be explained by a variety of 'residual factors', including economies of scale, improved health, skill and education of the labour force, improved organization, and technological innovation It should be noted that all the aforementioned factors, including labour and capital, are interdependent, and that conclusions about the individual 'contributions' of these residual factors must consequently be treated with the greatest care

That research and development influences the rate of industrial growth has been confirmed by a British investigation which shows that, over the past 25 years, the industrial sectors in the United Kingdom and the United States, which undertake relatively large amounts of research and development in relation to net output, are those in which total production has tended to grow rapidly and in which labour productivity is high Also, those industrial sectors are the same in both countries[7] The rapid growth would seem to indicate that research and development influences the rate of innovation, and its sameness in both countries that any new breakthrough in scientific knowledge is likely to benefit some economic sectors more than others

Nevertheless, it has been shown that even within an industry there tends to be a correlation between the amount of research and development undertaken in a company, relative to its size, and conventional signs of a company health, such as growth of net assets, productivity, profits and sales[8]. This correlation is not always strong, which is not surprising when one considers the many factors completely unrelated to research and development which can influence company growth However, even assuming that there is a correlation, this does not prove that research and development causes growth, and it has, in fact, been argued that growth either causes or enables companies to undertake more research and development This line of argument can, surely, safely be rejected in large part, since irrefutable evidence of the contribution of research and development to new and improved products is all around us

However, a more powerful line of argument is that both the volume of research and development expenditures and the various measures of company growth are results of something called 'good management' Common sense does in fact tell us that it requires good management to decide what sort of research and development to undertake, and to ensure that its results are effectively used In this context, it is worth noting that there is some evidence of a correlation between the growth of productivity of an industry or company, and the proportion of total employment in that industry or company which is made up of qualified scientists and engineers[9] One can conclude from this that good management increasingly requires some formal scientific or engineering training This has important implications for educational policy

To sum up, it can be said that those industries which are able to exploit scientific knowledge are growing rapidly, and that an adequate expenditure on research and development at the company-level is a necessary, though not sufficient, condition for growth.

Policies for Research, Innovation and Growth

From an economic point of view, research and development becomes of greater importance as a country becomes more industrialized With full or near-full employment and a small proportion of the working population in agriculture, increases in labour productivity will come from overall increases in labour productivity, together with the shifting of resources to the more productive industrial sectors of the economy From what has been shown here, both these conditions imply more research and development for economic purposes

Furthermore, if the economically advanced countries are to help the less-developed to produce more, to reduce unemployment and to find foreign exchange currency, one may regard it as their duty, as well as to their advantage, to move resources into the technologically advanced sectors, where they have a comparative advantage The less-developed countries need, and will continue to need for some time to come, markets in the advanced countries for simply manufactured products in such sectors as textiles and handicraft.

However, in the industrially advanced countries, the particularly long-term, risky and often costly nature of investment in research and development, and the often imperfect knowledge of industrialists as to its potential profitability, make it highly unlikely that an adequate level of expenditure on research and development for economic purposes will be achieved without governmental encouragement and help Some suggestions will therefore be made here about ways in which Governments can help to ensure an adequate level of research and development for the economy and rapid innovation

Scientific and Engineering Education. It is self-evident that the educational system should provide an adequate number of qualified scientists and engineers to undertake research and development for economic purposes. Such provision will require a considerable development of postgraduate investigations in science and engineering in many countries. Also scientists and engineers are wanted in increasing numbers in companies for related purposes From what has already been said, one can conclude that it is becoming increasingly difficult for managers without any scientific or engineering education to appreciate the economic value of some new scientific or technical discovery, or to give to the company's research and development workers the right problems to try to solve Scientists and engineers are therefore required to an increasing extent in general, production and sales management, in order to ensure that the results of research and development are fully and effectively used In this context we can include 'research and development' in such fields as market research, operational research and quality control

Adequate research and innovation in the economy therefore requires a generous supply of qualified scientists and engineers But it also requires, in many countries, that more persons of outstanding talent investigate applied science and engineering and that the content of this education be of high quality These requirements are shown clearly by the example of a country like Sweden, where industry is very responsive to the economic possibilities of technical change, and of the value of undertaking research and development This is largely because of the high academic and professional reputation of the Swedish institutes of technology, the entrance requirements of which are highly competitive, and the graduates of which are heavily represented among the leaders of Swedish industry

Economic and Fiscal Policies Research and development in a company is in the nature of an unusually long-term and risky investment, so that it presents problems even to enlightened management Uncertainty concerning the future prospects of the economy may make any long-term investment in research and development appear to be of little value, or may restrict capital investment programmes incorporating the results of past research and development Thus, general economic conditions and policies affect the amount of research and development undertaken in enterprises and the degree to which results of past research and development are used Scientific policy makers should bring these matters to the attention of their counterparts in ministries of finance, and should insist on the importance of an adequate overall level of demand in the economy, and of generous fiscal treatment with regard to company expenditures on research and development, and in certain cases to the writing off of past investments

Small or Backward Companies Many industries are made up of companies which are each too small to afford the men or money necessary to set up individual departments for research and development work In such industries, Governments can give aid and advice in setting up and running research and development establishments which care for the needs of a whole industry, and may be financed to some extent by companies in that industry Governmental research establishments already exist in most O E C D member countries to cover the needs of agriculture and building Industrial research associations similar to those in the United Kingdom exist in, for example, France, Holland, Norway, Sweden and Western Germany It is worth noting that industrial research associations can also be effective in industries made up of large firms when there is no technological competition

This form of governmental encouragement of research and development does not necessarily ensure that the results of the research and development are used, above all in small companies where management is often unable to appreciate their potential value Convincing management of the value of the results of research and development would appear to require not only an effective method of disseminating information from the research laboratory, but also a form of 'extension service', which is already widely used in agriculture Here, technical advisers are sent out to convince farmers of the value of recently developed techniques, and to assist them in putting these techniques into operation This is done to good effect in the industrial field by the T N O (Organization for Applied Scientific Research) in Holland, where about 20 per cent of industrial research and development is financed by firms with less than a thousand employees

Development Work Development work[4] represents the heaviest financial commitment of companies undertaking research and development programmes, accounting, on the average, for more than 75 per cent of the total cost of research and development work carried out in industry

In certain countries, development work in the aircraft and electronics industries is financed in large part by Governments as part of military, space or nuclear programmes The results of such development work can often be of use in the normal commercial operations of companies in these industries

However, in all countries, companies in the majority of industries rely on their own financial resources for the performance of development work, and it is clear that many are not able to undertake potentially profitable development programmes through lack of finance It can therefore be argued that Governments should make funds available for the performance of development work in the civil field in all industries, thus helping to restore a balance between those which benefit from governmental military, space and nuclear programmes and those which do not, and ensuring that no potentially profitable discovery is neglected through lack of funds for development work

Considerable efforts are already being made in this direction by the French Government, which is making funds available in increasingly large quantities Similar efforts, although on a smaller scale, are being made in Belgium and the United Kingdom In all the aforementioned countries, the Governments draw some financial benefit from development work which they help to finance and which proves to be commercially profitable

The Government as an Enlightened Buyer Even in the so-called capitalist countries, Government (central and local) is the largest single buyer of goods and services in the economy It is, therefore, in an excellent position to act as an enlightened buyer and to encourage, and even insist on, high technical standards from its suppliers This happens already to a large extent with governmental defence contracts in industry, because the fulfilment of the technical requirements specified by the Government in such contracts is considered to be of the highest national importance However, essentially the same thing happens in contracts between shirt manufacturers and Marks and Spencer

There is a growing awareness by Governments of the influence that they can have in this field In the United Kingdom, the Government is a customer for about 50 per cent of the output of the building industry and is making considerable efforts to improve building techniques[10] Similar developments are evident in the United States It is clear that the success which governmental departments have in encouraging innovation will depend largely on the degree to which they can call on technically competent staff

Obstacles to Innovation Some mention must be made here of factors which, although not directly related to research and development or to scientific policy, may nevertheless obstruct efforts to innovate and thus lead to a diminution of research and development activity Perhaps the most important obstacle to innovation can arise out of the restrictive attitude of a labour force which feels that innovation may upset established practices and, more specifically, lead to redundancy Governments can take effective action, in co-operation with industrial and Trade Union leaders, to overcome this obstacle by educating the labour force to the long-run advantages of innovation and, at the same time, by mitigating the worst short-run effects through an active programme for the retraining and redeployment of redundant workers Also Government rules and regulations may stifle innovation In the building industry, the use of new building methods and materials is often made impossible owing to statutory safety requirements, and mass-production and prefabrication often precluded through a lack of uniformity between locally required standards This is an obvious area where Government can act

Choice of Areas for Government Action The foregoing discussion shows that inadequate research and development and the inadequate use of scientific and technical knowledge for economic purposes can stem from a variety of causes, and that a variety of measures can be employed by Governments to try to put things right Some of the measures, such as the fiscal relief on research and development expenditures and those related to educational policy, are widespread in their effects Others, such as the setting up of industrial research associations and the awarding of development contracts, affect specific industries or firms.

It is very difficult in an article of this length, and knowing what we do at present, to assess the relative merits of these general and specific measures Such an assessment would, furthermore, be influenced by one's political leanings and by the circumstances existing in a particular country at a particular time However, it is possible to say a few words about the choice of priorities for governmental action in specific economic and technical sectors, since these choices are in fact being made In France, encouragement and aid to research and development are being given by the Government on the basis of the economic trends foreseen in the Fourth Economic Plan, and of the degree to which industries and companies 'import' their innovation from foreign countries in the form of patents and manufacturing licences. In the United States and the United Kingdom, efforts are being made to bring about innovation in the building industry, because present techniques are inadequate to fulfil expected future needs. In the United Kingdom, efforts have been made to improve the level of research and development in industries which, by comparison with other countries, were comparatively weak[11], and recommendations have been made that the allocation of funds to research and development should be influenced by the degree to which such an allocation might promote exports or save imports[12]

It is clear that, given that the financial and human capacity for research and development of a country is limited in the short run, choices of priorities will be made to an increasing extent, either explicitly or implicitly, in future It is to be hoped that economic criteria will be fully considered when these choices are being made

Scientific Discovery and Innovation Outside the Economy

So far, this paper has considered only research and development undertaken for economic purposes, and I have said that more of it is being done It must never be forgotten, however, that research and development is undertaken for other purposes, and that more of it is being done This other research and development accounts for more than half the national expenditures in certain countries In some cases it competes with the economy for research and development resources, and in some cases it complements the efforts of the economy We shall discuss here the two most important components of this other research and development namely, military and 'prestige' research and fundamental research

Military and Prestige Research National military strength is no longer primarily a function of the number of infantrymen nor even of industrial potential but rather of the quantity and quality of certain types of scientific and technological activity Similarly, prestige in foreign policy no longer depends on gunboats but on the technical virtuosity of space satellites. Certain Governments, therefore, spend a great deal of money, and employ a large number of scientists and engineers, on research and development as part of defence, nuclear and space programmes More than 70 per cent of the funds provided for research and development by the Governments of France, the United Kingdom and the United States are in these three fields

The main purpose of research and development work as part of national defence, nuclear[13] or space programmes is not to provide goods and services for the public, although knowledge of economic value may be produced by accident. However, a large part of the research and development work is undertaken in companies with civilian interests—mainly in the aircraft and electronics industries—so that some of the work may find civilian applications Nevertheless, some reservations are being expressed concerning the overall economic benefits of military and prestige research[14]. It is being argued that the nature of the problems being solved is becoming very different from those which concern the mainly earthbound economy, and that the possibilities of 'spin-off' from the military and prestige to the civilian field are diminishing

Furthermore, research and development projects for defence and space are competing with research and development projects in the economy and in the universities for the services of a comparatively restricted supply of people capable of undertaking research and development Large-scale programmes in defence and space can, if not carefully watched, lead to rapid increases in the salaries of research workers, or to unfilled vacancies in other research and development projects and in the teaching posts in the universities, without any real increase in the quantity of research and development activity actually undertaken

There is, in fact, some evidence that the three-fold increase in expenditure in the United States on defence and space research over the past ten years has led to a levelling off of research and development for economic purposes[14] By contrast, research and development for defence purposes over the past eight years in the United Kingdom has remained approximately constant as a proportion of gross national product, whereas research and development for economic purposes has seen a three-fold increase[15] Given, however, that many Governments will find it necessary to have large-scale research and development programmes in defence and space, scientific policy makers should ensure that these enormous programmes are well managed and that there is no unnecessary waste of money or—more important—men[16] At the same time they should ensure that, so far as the need for secrecy allows, the scientific and technical knowledge accumulated as a result of military and space programmes should be made readily available to industry and the universities

Fundamental Research Most fundamental research is undertaken in the universities or technical colleges, although a certain amount is carried out in governmental laboratories and in industry The increasing practical utility of science and technology has led to the increasing demand for scientists and technologists, so that the scientific and engineering faculties of the universities are expanding[17], and so are the facilities for research

An adequate level of fundamental research is, in the long run, an essential pre-requisite for innovation and economic growth Many modern industries are based on the discoveries of scientists who, at the outset, had no interest in the potential economic usefulness of their work Attempts to 'direct' fundamental research or to restrict the distribution of its results often meet with stiff opposition from the scientific community. This is right and proper on cultural and ethical grounds It is also right and proper on economic grounds, since most good scientists are more productive when following ideas of their own choosing, and their discoveries are more likely to find some practical application if the results of their work have wide and unrestricted distribution.

In most countries, the largest proportion of funds for fundamental research comes from Government It is, therefore, very important that the holders of the public purse take a generous and long-term view of expenditure on fundamental research, and that they evolve an effective method of providing adequate funds for fundamental research, above all in the universities

At the same time, both the nature and the role of fundamental research is changing It is becoming increasingly concerned with 'unnatural' states of, say, distance, speed, size, time, temperature and pressure[18] Heavy expenditure on equipment is often required to bring about these states, and increasingly refined techniques are required to measure and record them Moreover, there are now many remarkable aids to calculation, but they cost a great deal of money. This often means that special Government grants are now needed to set up research institutes which are used by more than one university—such as the National Institute for Research in the Nuclear Sciences at Harwell

Furthermore, fundamental research is becoming of practical importance, mainly as a result of the advance of techniques in the military, space and industrial fields 'Oriented' fundamental research is therefore being undertaken in industrial, governmental and university laboratories In the United States, the growth of oriented fundamental research mainly as a result of governmental and industrial contracts with the universities has been particularly rapid It is clear that Government should help ensure that industry and Government have fruitful contacts with the universities concerning oriented fundamental research. At the same time, however, it should be careful to ensure that the oriented research work does not swamp out the very necessary free fundamental research

[4] The definitions of research and development used by the National Science Foundation for statistical surveys in the United States are the following

Research is systematic, intensive study directed towards fuller knowledge of the subject studied Research may be either basic (that is, fundamental) or applied

Basic (that is, fundamental) research is directed toward increase of knowledge, it is research where the primary aim of the investigator is a fuller knowledge or understanding of the subject under study rather than a practical application thereof

Applied research is directed toward practical applications of knowledge

Development is the systematic use of knowledge directed toward the design and production of useful prototypes, materials, devices, systems, methods or processes It does not include quality control or routine production testing

The fields of science covered by these surveys consist of the engineering, physical and life sciences

PROBLEMS OF ECONOMIC GROWTH*

By Prof C. F. CARTER

Vice-Chancellor of the University of Lancaster and Joint Editor of the *Economic Journal*

THERE are two problems of growth one is how to begin and sustain the process in those countries which remain very poor, and the other is how to influence the rate of growth of developed countries In discussing these, it is important to keep a firm control of our time perspective A compound rate of growth of production per head at 5 per cent per annum is sufficient to give an increase of 11½ times in 50 years (which is enough to get the Indian standard of living within striking distance of that at present enjoyed by the United States), or of 132 times in a century Small differentials in growth-rates, operating over quite a short time in the history of the human race, are sufficient to produce large differences between rich and poor nations High *per capita* growth rates (of the kind, for example, which Britain hopes to achieve through the National Economic Development Council) must necessarily be a short-lived phenomenon when considered against the whole scale of history It is plausible that, with the substitution of new materials and sources of energy, the world can produce five times what it now produces, it is not plausible that it can produce a hundred times as much, either in total or per head, nor does it seem very likely that the human race would desire to create material wealth on this scale During the next century the increasing difficulty and real cost of winning extra supplies, and the cost of finding or making substitutes for easily won natural materials, may slow down the achievable rate of growth below the rate of rise of population, so that the world average income per head would necessarily fall

It follows that, so far from the future holding a promise of Cadillac motor-cars for Indian farmers and ever-larger television screens in the villages of Africa, our grandchildren or great-grandchildren might belong (on average) to the richest generation ever to dwell on this planet, at least until the human race learns to control its numbers, and the peak would be reached at a time when serious poverty was still the fate of a large part of the human race Beyond that time there would be a direct conflict between the relief of poverty and the desire of the rich to become still richer

The flow of wealth is created by the application of human effort, skill and ingenuity to the resources provided by Nature and to the stock of capital goods created in past times, within the framework of a particular method of organizing production and exchange It follows that economic growth requires one or more of the following more human effort, more skill and ingenuity (including here the use of a more advanced technology), the discovery of more natural resources, more capital goods (of an appropriate kind), more appropriate organization

Economists have sometimes given the impression that the key factor in economic growth is the size of the stock of capital In consequence, a country wishing to achieve rapid growth was to tighten its belt, to use less for its immediate needs, and to divert its effort to the creation of a capital stock to produce wealth in the future This, we were told, was the great secret of the growth of the Soviet economy It was an unhappy implication that those countries most in need of growth would find it hardest to achieve, because they would be too poor to divert resources from current consumption

Now, since economic growth usually involves the production of new kinds of goods, it is no doubt generally true that it involves the creation of new capital to make those goods But where several influences work together to create a result, it is dangerous to label one as a 'key factor'. It seems *a priori* more likely that the most important influences on growth will differ from one country to another and from one period to another Furthermore, the influence of a stock (whether of capital, natural resources, or knowledge) depends not only on its absolute size but also on the effectiveness of its exploitation Machines which work one shift can be made to work three, railway lines which carry trains once an hour can carry them every ten minutes It does not follow that, because the British rate of growth is low, therefore we immediately need a lot more capital Perhaps for a considerable period we need only make better use of what we have got already

(Mr Carter then illustrated the importance of alternative influences on growth by discussing a series of propositions, two of which were as follows)

---

* Substance of an evening discourse delivered on August 30 to the British Association meeting in Aberdeen

(I) *In the short period, Britain could have a 5 per cent growth-rate if people worked harder and longer.* Such a proposition might not be true if applied to an Indian village, where people already work as hard as a diseased and under-nourished state allows. But few of us in Britain have reached the limit of our capacity to work; and we often, in common gossip, ascribe our lack of economic progress to our failure to work as hard as (say) the Germans or the Japanese. Why, then, do we not work harder? Or (to put it another way) why are there periods in which the energies of a community are easily stimulated and released, and other periods when men demand action of others which they will not give themselves?

The question is an obvious one; but it is not answered by sermons, political speeches, or leaders in *The Times*, calling for a 'new sense of national purpose'. This only states the problem: Why does the sense of national purpose vary? The social influences on intensity of effort remain, in fact, somewhat mysterious, despite the many millions of words which have been written about them—probably, again, because they are various, and operate in different combinations and to different degrees at different times and places. I select a few pointers:

(*a*) People will not work hard to create material wealth unless it is considered desirable and respectable to enjoy the fruits of their labour; in this sense economic growth requires a 'materialistic' society.

(*b*) They will not work hard unless they can imagine themselves attaining the desirable consequences. Energy is released by the spread of the use of money in an economy formerly producing for subsistence within closed village or family communities, for money carries the power to break out into a new kind of life, to buy the products of the towns or to emigrate. In a developed community, energy is stimulated by strong social pressure to keep up with the neighbours; the best achieved within our social group is the object of our own imaginings.

(*c*) It follows that a society with marked class or caste or racial barriers will offer an inferior stimulus; if a man knows or believes that he cannot rise far, why should he bother? Why work to get a Rolls-Royce motor-car if one is confined for life to a social group satisfied with a Mini-Minor car?

(*d*) The extent of people's effort depends on the weight which they put on the co-operative, as against the competitive, aspects of society. All economic life, in any society, involves elements both of co-operation and of conflict. But in some societies a man who works harder sees his efforts as benefiting 'Them'—the bosses, the shareholders, the Government—while in others he sees first the benefit to himself and to 'Us', the common interest in economic growth. These points of view bear no apparent relation to the actual division of the benefits, though they are perhaps related to the extent to which social divisions run along lines which separate economic functions.

(*e*) People will not work hard if they see the results of their efforts running away in waste and frustration. Three points are important here. First, the economic system must be organized with reasonable efficiency and honesty: lack of economic growth can sometimes be blamed on an inflexible and stupid administration, or on a prevalence of bribery and corruption. Secondly, the vigour of new ideas must not be suffocated by a dead weight of orthodoxy; and a problem here is that an orthodox community may not even realize that it is resisting new ideas. Thirdly, the energy of the young must not be frustrated by the power of the old. A system which closely relates influence to seniority, and which regards it as a positive advantage to be ruled by old men, is no place to expect rapid economic growth.

(II) *Economic growth depends on the level of education.* This is one of those remarks the apparently self-evident truth of which conceals the fact that it does not mean very much. There are several different ways in which lack of educational facilities may inhibit economic growth, and they call for different remedies, which are not accurately described by a general phrase about 'raising the level of education'. First of all, there may be specific shortages of technical skill—say, a lack of design engineers or of soil scientists. Such shortages, if they affect major sectors of the economy which in other respects are ready for vigorous growth, can properly be regarded as 'key factors', and they call for specific efforts of training or re-training applied to limited groups of people. Secondly, the spread between efficient and backward producers may be too great. This calls for an educational effort of a complex kind. It must predominantly be adult education if it is to take effect in a reasonable time. It must start by identifying why backward producers tolerate their own backwardness. Are they merely ignorant? Are they enjoying an easy protected life, without the trials of keeping in the front? Are the incentives to improve their ways too small? Are they held back by social pressures, or religious scruples, or faults of organization? To treat the disease by technical education assumes that ignorance is the main factor—that if the producer is told of a better way, he will follow it; and this is not necessarily true.

Thirdly, a generally higher level of education may contribute to economic growth by increasing adaptability to change. This idea involves, not instruction to meet a known need, but the development of ability and personality to meet unknown situations in the future. Instruction to meet a known need may, in fact, inhibit growth, if people become fixed in their habits of thought. We are, I think, in Britain in danger of getting too much instruction in technology and too little education in creative technological thinking; and though this may help to relieve certain specific shortages of skill, it does not sufficiently assist our adaptation to changing conditions of trade.

Fourthly, education may assist growth by altering the problem of communication. This is most obviously true of learning to read and write; the written instruction and message can replace the fallible memory of a verbal communication. Similarly, an improvement in what is now called 'numeracy' widens the range and precision of communication; a man who can interpret a graph, or read the message of a table of statistics, can acquire ideas more rapidly and accurately than he can from words alone. Again, if a country gives specialist scientific training to more people, it increases the number of those who are 'tuned to the same wave-length' as scientists in other countries—it provides itself with listening or observation posts, so that it becomes more likely than before to pick up new ideas quickly and effectively.

But more of the wrong kind of education may waste ability while doing nothing to promote economic growth; it may merely create a class of educated unemployables. More, even of the right kind of education, is achieved only at a cost—a shortening of working life, a diversion of ability into the teaching profession. The universities of Britain, for example, have a very large and increasing appetite for the services of their own most able graduates. First-rate ability is in desperately short supply, in industry, commerce, the professions and Government service. It is not entirely fanciful to suppose that in the short run our very necessary university expansion may be harmful to economic growth.

In my reading of past history I do not find, and I do not expect to find, any one cause of stagnation, or any one system of remedies for it. The way to economic growth is to be found through a profound understanding, not only of the economic influences bearing on a community, but also of its social structure and ways of thought. For this reason I am very doubtful of the value of dispatching economic experts to help underdeveloped countries to achieve development—except that an expert may provide outside authority for doing something already seen to be desirable but difficult to achieve.

For Britain, there is no technical or economic difficulty in achieving and maintaining for a considerable period a 4 or 5 per cent rate of growth. The resistant difficulties will, I think, be found to lie in our social structure and habits of thought: in the sharp class distinctions between master and men; in the traditions of trade union bargaining and cost-plus pricing; in the pressures of democracy to get benefits now at the expense of the future. There is no simple formula to dissolve these difficulties.

INCREASE IN RADIOCARBON FROM THE MOST RECENT SERIES OF THERMONUCLEAR TESTS

By REIDAR NYDAL

Radiological Dating Laboratory, Norwegian Institute of Technology, Trondheim, Norway

BEFORE development of the atomic bomb, the natural production of carbon-14 in the atmosphere was only effected by the cosmic ray neutrons (*n*), as nuclear reaction with nitrogen atoms (nitrogen-14) in the air produced the carbon-14 isotope according to the equation:

$$^{14}N + n = {}^{14}C + {}^{1}H$$

The natural equilibrium between production and disintegration of carbon-14 in the world reservoirs has been disturbed by atom bomb explosions, where liberated neutrons produce additional carbon-14 in the atmosphere. For explosions in the atmosphere the number of carbon-14 atoms produced is nearly equal to the number of liberated neutrons.

The first nuclear bombs operated by the fission of uranium or plutonium produced large quantities of fission isotopes such as strontium-90, cæsium-137 and iodine-131. In the hydrogen bomb, however, the main energy is released by a fusion reaction which does not result in liberation of fission products. The neutron yield per megaton in a fusion reaction may be greater than for fission. According to results obtained by Leipunsky[1], $2 \cdot 2 - 32 \times 10^{26}$ neutrons per megaton were released by various fusion reactions. For explosions prior to 1959 the total observed neutron yield (fission and fusion) was close to 2×10^{26} neutrons per megaton[2]. This was, however, a mean value derived from different types of nuclear weapons.

Radiocarbon in the atmosphere from nuclear tests has already been investigated by several authors[3]. The large series of thermonuclear tests carried out in 1961 (150 Mtons) and in 1962 (320 Mtons) have caused a more dramatic rise in artificial radiocarbon than before, and I have therefore considered it important to follow the recent increase in radiocarbon content of the troposphere and biosphere. The two main purposes of the present investigation are the following: (1) to obtain exact data on terrestrial carbon-14 activity for estimating the human hazard; (2) to examine transport processes in the atmosphere.

The recent international agreement on prohibition of nuclear tests in the atmosphere gives excellent opportunity to examine the distribution of carbon-14 from the later bomb series, which were mainly injected at the polar cap.

In Trondheim I began measurements of carbon-14 in the atmosphere in May 1962. In order to study meridional transport and increase in carbon-14 at various latitudes, several persons have collected weekly samples for the laboratory since March 1963, from Addis Abeba (9° N.) to Spitsbergen (78° N.). As seen in Fig. 1, the stations (dark rectangles) are mainly placed along the coastline of the continents and far away from large towns and industrial centres. Every precaution is taken to avoid carbon dioxide from local sources.

I used the method[4] of direct absorption by sodium hydroxide of carbon dioxide from the air. Generally, a solution amount of 2 l. 1/2 N sodium hydroxide in each of two dishes was used. Each dish has a cross-section of about 450 cm^2. For practical reasons, an absorption time of 7 days (from one Monday to the next) was generally used for each sample. The amount of carbon dioxide absorbed during this time varies widely (3–8 l.), depending on temperature and humidity of the air. During the

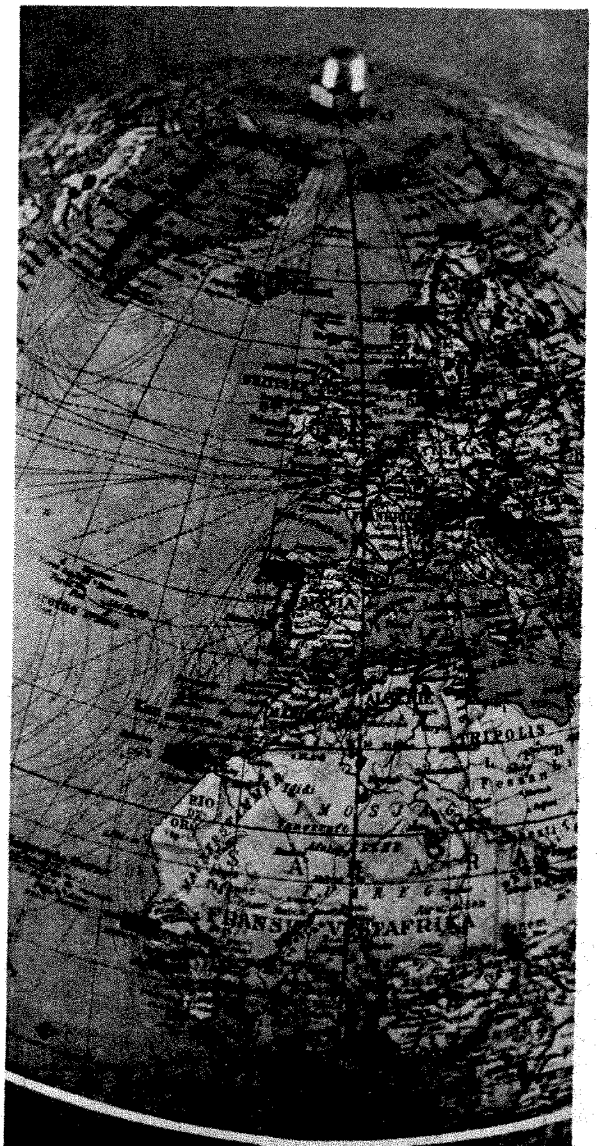

Fig. 1. Dark rectangles show the localities where weekly samples of carbon dioxide were collected from the air

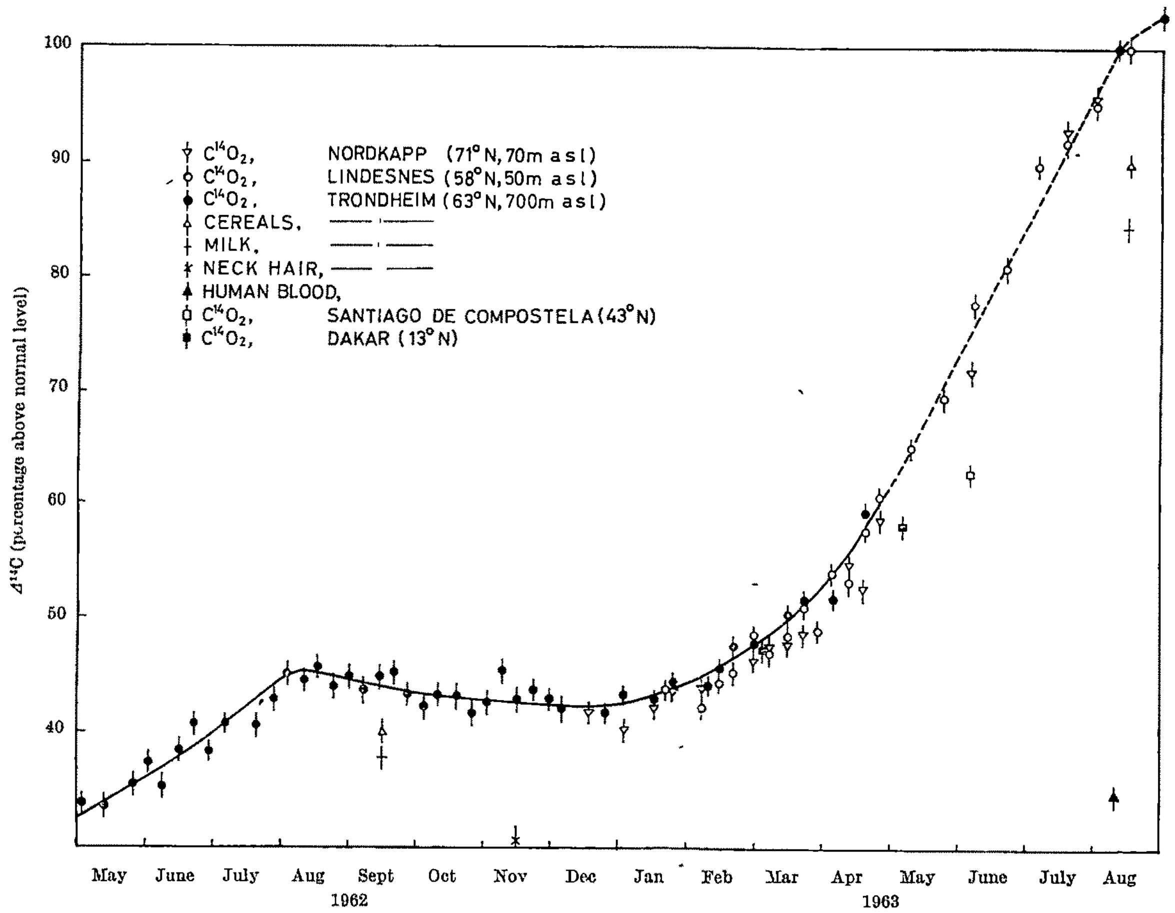

Fig 2 Increase in radiocarbon in the northern hemisphere

winter in northern latitudes, a thermostatically controlled heater element of 40 W in each dish served to keep the temperature slightly above zero °C

A fractionation between the carbon isotopes takes place during the absorption In order to make the measurements directly comparable with the oxalic acid standard[5] from the U S National Bureau of Standards, most of the samples are measured for fractionation error by mass-spectrometrical analysis of the $^{13}C/^{12}C$ ratio It turned out, however, that fractionation of the samples of carbon dioxide was very close to that found in vegetation Correction in the activity is only applied in a few single cases where the deviation is more than about 2 parts per thousand from the normal value

Generally, the percentage deviation in activity of carbon-14 ($\Delta^{14}C$) from the recent standard is calculated as

$$\Delta^{14}C = \frac{I - 0\ 95\ I^{\circ}}{0\ 95\ I^{\circ}} \times 100$$

where I represents the activity in the air sample, and 0 95 I° the normal activity in recent wood

The samples are partly measured in a carbon dioxide proportional counter, earlier described[6], and partly in a second counter with a background of 3 5 counts/min and a recent standard net count of 14 2 counts/min Generally, a counting time of more than 24 h is applied for each sample The limit of error for each measurement is one standard deviation

The percentage increase ($\Delta^{14}C$) in radiocarbon versus time given in Fig 2 shows a curve which is mainly the result of nuclear tests carried out in 1961 and 1962 The curve shows the typical seasonal variation, with increase in activity between January and August, and a decrease the rest of the year The variation is due to the transport mechanism from the stratosphere to the troposphere During large thermonuclear explosions, the radioactive elements are injected in the stratosphere The transfer back to the troposphere seems to some extent to be dependent on seasonal variation in the height of the tropopause[7,8], which shows larger heights in summer than in winter on northern latitudes In summer the turbulent motion in the troposphere is able to reach greater atmospheric heights, and parts of the lower stratosphere will then be incorporated in the troposphere This results in a much larger transport downwards in summer than in winter

In August 1963 a doubling of the normal carbon-14 level in the troposphere was observed on high northern latitudes Only a few samples are measured from Dakar (13° N) and Santiago de Compostela (43° N), but the measurements here indicate that the increase is about uniform in the northern hemisphere In the last four months of this year a decrease in activity up to 10 per cent is predicted because of the transfer of radiocarbon to the ocean and the southern hemisphere It is rather difficult to predict the prospective rise in tropospheric radiocarbon the following years, as we do not know exactly (1) the neutron yield of the bombs, (2) the altitude for the injection of radiocarbon

According to our observations, about 15 × 10^{27} carbon-14 atoms have until now been transferred to the troposphere from the 470 megaton thermonuclear explosions during 1961 and 1962 This amount constitutes only 15 per cent of the minimum amount of carbon-14 injected in the stratosphere in the period mentioned If this is correct, the tropospheric carbon-14 level will continue to rise for some years The period of existence of a carbon-14 atom in the troposphere is 6–7 years[3], before it is absorbed in the ocean This absorption will further determine the decrease in the troposphere until stabilization occurs in about 50 years After that time the remaining bomb carbon-14 will decay with a half-life of 5,700 years

By the process of photosynthesis in plants the radiocarbon is transferred to the biosphere Unfortunately, the growing season in northern latitudes coincides with the time of maximum increase in radiocarbon The samples of cereals measured in 1962 and 1963 show a specific activity not far from the maximum carbon-14 content in the troposphere in the respective years (Fig 2) This is also the case with the two samples of cows' milk from the local dairy at Trondheim A prediction of the carbon-14 rise in the human population is somewhat complicated because of varying diets This question is treated by Broecker *et al* [9], who found a time-lag in carbon-14 content between parts of the human organism and the troposphere of 1–2 years The authors state that the time-lag is due to (1) the time between photosynthesis of food and consumption by human beings, (2) the length of time the carbon remain in human tissue

Up to the present only two samples from human organisms have been measured in our laboratory The first sample was hair of the neck of a baby born on February 21, 1962 The hair which was cut for the first time on November 15, 1962, showed a carbon-14 activity of 30 70 ± 1 35 per cent above normal level The child's diet in the present case was perhaps somewhat unusual, because it consisted mainly of cows' milk for the past six months

The second sample was blood from a person twenty-four years old The sample, which was collected on September 9, 1963, showed an increase of 34 85 ± 1 10 per cent above normal. The activity corresponds to a time-lag behind the tropospheric level of 1 3 years, a result which fairly agrees with that found by Broecker (1·1 year) It is reasonable to assume that in future the amount of carbon-14 in the human population will rise to a maximum value, close to that of the final tropospheric level Even if no further nuclear tests are carried out, it is already obvious that this amount will at least be 2–3 times the normal activity within a few years Further measurements are needed, however, in order to obtain more exact information

I thank the following for collecting samples at various latitudes Mr Kåre Henriksen, Isfjord Radio, Spitsbergen, Mr Arild Klefstad, Fruholmen, Nordkap, Mr. Reimert Rasmussen, Lindesnes, Mr Enrique Lazo Alcola del Olmo, Santiago de Compostela, Mr Nicolás Miguel Zalote and collaborators, St Cruz, Tenerife, Dr C A Rouiller, jun , NASA, Project Mercury, Gran Canaria, Dr P Elouard, Université Dakar–Fann, Mr Oskar Nydal and Mr Hadle Hovda, Evangelical College, Addis Abeba

I also thank the following authorities, Dr José Antonio Barasoain and Dr Pio Pita Suarez de Cobián, of the Ministerio del Aire, Madrid, for assistance in arranging the sampling in Santiago and Tenerife

This work was supported by the Norges Almenvitenskapelige Forskningsråd and Norges Tekniske Hogskoles Fond

OBITUARIES

Sir Geoffrey Evans, C.I E.

Sir Geoffrey Evans, who died on August 16 at the age of eighty, was a man of exceptional experience in tropical agriculture, and one who played an influential part in the organization and development of agriculture in Commonwealth countries His wide experience was gained in an active life of service abroad

From his home in a Lancashire vicarage and from school in Bury, Geoffrey Evans entered Downing College, Cambridge, in 1901, to read for the natural sciences tripos and then to take an agricultural diploma He remained in Cambridge on the staff of the School of Agriculture for a further year before taking an appointment in the Indian Agricultural Service He sailed for India in 1906 to become, in the words of an earlier biographer, "one of the early band of stalwarts who laid the foundations of the Indian Agricultural Service" During his time in India, which extended until 1923. his various posts included those of principal of the Agricultural College at Nagpur, deputy director of agriculture for a large district in the Central Provinces, and finally director of agriculture in Bengal

During the First World War, as an officer trained in the Indian Army Reserve, Evans saw active service in Iraq Use was there made of his technical knowledge, and he was appointed director of agriculture to the Mesopotamia Expeditionary Force with rank of colonel He also had an opportunity to visit Burma when chosen to advise on organization of its agricultural department Characteristically, in his report he stressed the importance of sound agricultural training, and one of his recommendations led to the founding of the Agricultural College at Mandalay

On leaving India in 1923, Evans took an appointment with the Empire Cotton Growing Corporation as director of cotton culture to the Queensland Government His three years in Australia he himself described as "somewhat strenuous, but most interesting" He arrived at a time when a boom in cotton-growing was collapsing and when the Government was introducing unpopular measures for regulating its planting He remained long enough to see some order return, to improve the seed-supply, to train a team of efficient field-officers, and to see started a well-equipped Cotton Research Station He found time to visit Fiji to advise on possibilities of extending cotton cultivation there, and wrote a typically helpful report outlining practical measures to be taken for establishing the industry on a sound basis A visit for the same purpose was later paid to Papua and New Guinea

Evans's experience was, therefore, already wide and varied when, in 1926, he was invited to join the staff of the Imperial College of Tropical Agriculture, Trinidad In the following year he was confirmed as principal, a post he was to fill for twelve years with outstanding ability The College, which had been formally opened in 1922, owed much to the inspiration of Viscount Milner, who envisaged it not only as a regional agricultural college for the West Indies but also as a place where men would be trained to serve as agriculturists throughout the British tropical possessions, and as a centre for fundamental research on tropical crops When Evans came, a good start had been made, but building had yet to be completed and land fully acquired finances remained insecure, the aims and courses of study had still to be fully worked out, and research policy planned It fell to Evans to make a working reality of the proposals of Milner, and the measure of his success may be gauged by the ability of the staff who were attracted to the College, by the high reputation for training which the College soon acquired, and by its fine record of research accomplished

While he has been described as helping to lay the foundations of the Indian Agricultural Service, it can be said with no less force that he did much to fashion the Colonial Agricultural Service Not the least important task of the College was the training of staff to man the Colonial departments of agriculture, and most of the officers recruited in that period could look back, in pleasurable memory, to the College under Evans

Evans left Trinidad in 1938 to become economic botanist at Kew, a position in which his wide knowledge of tropical crops could be well utilized In 1941, on the sudden death of Sir Arthur Hill, director of Kew, Evans was called on to act in his place, and he administered the affairs of Kew for two of the difficult war-years, leading its force of local defence volunteers, and afterwards commanding the Home Guard of the adjoining borough of Richmond

He remained as economic botanist until the end of 1953, taking special interest in the provision of useful plants to countries of the Commonwealth and their growing under conditions of quarantine at Kew He served as chairman of the Colonial Committee on Anti-locust Research, as a member of the Committee on Colonial Agricultural Research, and on various other committees and Government commissions During 1947–48 he was chairman of a commission appointed to examine the possibilities provided by British Guiana and British Honduras for settlement of people from over-populated West Indian islands and of people displaced from European countries Few commissions can have been as energetic as this one, as led by their chairman, ever an active man, they travelled by canoe and by jeep, on horseback and on foot, seeking areas fit for development in the interior of these countries Although little action followed publication of the report, it remains an admirable account of the resources of these territories and means for their development

On retiring to his home in Sussex from Kew and from his various committees, he yet retained one post in which he took a special interest, and, as chairman of the committee managing the National Pinetum at Bedgebury in Kent, he supervised with almost paternal care the progress of the coniferous plantings

Geoffrey Evans was honoured for his work in the First World War by the award of the C I.E , and was knighted in 1934 in recognition of his work in Trinidad He was honoured in a wider sense by those knowing him who respected his upright character and responded to the warmth of his genial and kindly friendliness The regard in which he was held extended equally to Lady Evans, who, after sharing his life for forty-nine years, survives him along with their two daughters T A RUSSELL

Dr. Francis M. Defandorf

DR FRANCIS MARION DEFANDORF, an authority in the field of high-voltage measurements at the U S National Bureau of Standards, died on August 18 He was born in Garrett Park, Maryland, in 1897 He received his bachelor's degree in electrical engineering from the Johns Hopkins University in 1920, a master's degree from Harvard in 1923, and a Ph D from Johns Hopkins in 1927

His professional career was at the National Bureau of Standards, where he first worked on a summer task in 1916 He rose to become chief of the Electrical Instruments Section for the last seventeen years of his life Here his broad knowledge, meticulous care and dedication to the task at hand served as inspiration to his associates The present 2-million-volt High Voltage Laboratory of the Bureau is in large measure the result of his initiative in starting it, his skill in planning it, and his wisdom in directing its development

He was very active in local civic and scientific matters His services to the Philosophical Society of Washington and to the Washington Academy of Sciences were recognized by his election to the presidency of each in 1946 and 1954, respectively He was a Fellow of the American Institute of Electrical Engineers and active in the work of its local section, of which he was chairman in 1941–42 He also devoted much effort to the national standardizing work of the American Institute of Electrical Engineers and of the American Standards Association, particularly in the field of lightning protection He was the author of a number of technical papers on lightning and on methods for measuring very high voltages

During the Second World War and the Korean conflict, he was engaged in highly classified applications of electricity

NEWS and VIEWS

The Sir William Dunn School of Pathology, University of Oxford. Sir Howard Florey, P R S

SIR HOWARD FLOREY, who became professor of pathology at Oxford in 1935, is now the Provost of the Queen's College and has relinquished the chair Sir Howard has made unrivalled contributions to the development of pathology as an experimental science in Britain His work has ranged from the study of inflammation and mucus secretion to the discovery, with Prof E B Chain and other colleagues, of the chemotherapeutic properties of penicillin and, more recently, to investigations with the electron microscope relating to occlusive diseases of the arteries His distinction has been recognized by the award, in 1945, of the Nobel Prize in Physiology and Medicine and of the Royal and Copley Medals of the Royal Society His outlook and leadership have made the Sir William Dunn School of Pathology a unique department of its kind, and fortunately he will be able to continue his work there At the same time, he will be well placed, as Provost of Queen's, to express his views effectively on matters relating to science in the University Sir Howard was elected a Fellow of the Royal Society in 1941, and first served on the Council during 1942–43 For the period 1951–53 he was a vice-president and in 1960 was elected president (see *Nature*, 188, 896, 1960)

Prof. H. Harris

SIR HOWARD has been succeeded in the chair and in a professorial fellowship at Lincoln College by Dr Henry Harris, who graduated at the University of Sydney, first in the Faculty of Arts and then in Medicine Dr Harris went to the Sir William Dunn School of Pathology, Oxford, in 1950 with a travelling fellowship from the Australian National University and continued to work there until 1959 After a year in the United States he became head of a new Department of Cell Biology at the John Innes Institute His first work at Oxford, which upset the prevailing view on the nature of chemotaxis in leucocytes, led to investigations on the physiology of other mammalian cells, and in recent years he has made significant and interesting contributions to our knowledge of the biological role of the ribonucleic acids in cell nuclei Dr Harris is a man with an unusual collection of abilities His appointment ensures that the Sir William Dunn School of Pathology will retain the character it acquired from his predecessor

Towards the Organization of Science by Scientists

THOSE concerned with the organization and teaching of science in Britain could well consider the possibility of introducing a compulsory one-year course on the administration and organization of science for all undergraduate students of science How many undergraduates are sufficiently well informed to understand the inosculations of the science effort, the workings of the Research Councils, the research associations, or science in industry or university? Such a course could include an appreciation of the interactions of science and the State—and where better could the student start than Prof R V Jones's address, on September 3, to Section X (General) of the British Association for the Advancement of Science meeting, in Aberdeen, on the life of Lyon Playfair (see *Nature*, **200**, 105, 197, 1963)? Few students (and many qualified scientists) really appreciate the interrelationships of science and Government, the workings of the University Grants Committee, or even what D S I R stands for, let alone have heard of Lyon Playfair, Colonel Strange, H E Armstrong, Sir Richard Gregory, etc , to mention a few The approach to the subject would best be historical and possibly subdivided as Playfair did his presidential address to the British Association in 1885, and which Prof Jones developed If such a course could be introduced by one compulsory lecture a week, all potential scientists would gain a better appreciation of the inherent difficulties of organizing the national science effort It would, in the long run, lead to the organization of science by scientists

Peaceful Uses of Atomic Energy

THE third International Conference on the Peaceful Uses of Atomic Energy will be held in Geneva during August 31–September 9, 1964 A provisional topical agenda constituting the general programme of the Conference has been prepared by the United Nations with the advice of the Scientific Advisory Committee and in co-operation with the International Atomic Energy Agency The main theme of the Conference will be new developments in power reactor technology, including descriptions of, experience with and prospects for reactor systems, economic aspects of nuclear power, nuclear fuel and other reactor materials, reactor physics and performance studies, safety implications and radioactive waste management Sessions are also proposed on new developments in controlled thermonuclear reactions, application of radioisotopes, research reactors and isotope separation and other new applications of atomic energy A scientific exhibition in connexion with the conference will be organized and participation will be limited to States taking part in the conference

Sir William Penney, deputy chairman of the United Kingdom Atomic Energy Authority, has been appointed chairman of a National Executive Committee with members representing the interests of the Atomic Energy Authority, Electricity Boards, the nuclear industry, Government Departments, universities and research organizations A committee has also been set up under the chairmanship of Sir William Penney to prepare papers for submission by the United Kingdom to the United Nations The Atomic Energy Authority is to provide the Secretariat, which will be responsible for all executive and administrative arrangements on behalf of the United Kingdom relating to papers, the exhibition and attendance at the conference, under the general guidance of the National Executive and Papers Committees For this purpose the Authority has established a Geneva Conference Secretariat at its London Office, 11 Charles II Street, London, S.W 1, under the direction of Dr J Gaunt

Scientific Research in France

THE *Rapport National de Conjoncture* for 1962–63 of the National Centre for Scientific Research, Paris, also entitled the "Report of the National Committee for Scientific Research", covers all the research proceeding under the Committee during the year, in which the number of research workers increased from 650 to 720 (Pp 264 Paris Centre National de la Recherche Scientifique, 1963) The information on current projects is arranged according to divisions of science and not institutions and the report is in two parts, the first dealing with the exact and natural sciences, and the second with the human sciences, including philosophy There is no index, but fairly full contents pages facilitate reference The whole volume is itself too condensed to permit further condensation without distortion

The Lister Institute of Preventive Medicine

THE report of the Governing Body of the Lister Institute of Preventive Medicine for the year 1962 includes a summary of the investigations made in 1962 (Pp 33 London Lister Institute of Preventive Medicine, 1963) In microbiology, the Guinness–Lister Unit continued to explore bacterial genetics, mainly of the *Salmonella* bacilli. The Trachoma Research Unit continued its epidemiological field study in the Gambia of trachoma in terms of virus and of bacilli of the *Haemophilus* group and is preparing to test the prophylactic value of a virus in the Gambia The immunological study of bacterial infections included an analysis of the action of two types of protective antibody in mice infected with the whooping cough bacillus, the laboratory assay of typhoid vaccines and the nature of the protective antigen in typhoid vaccines for human use, the immuno-pathology of actinomycetic dermatitis of sheep, and the process of refinement of antitoxin by proteolysis Work continued on the relation of serum permeability factors to plasma kininogenases and their respective roles in vascular reactions to injury Biochemical research work again concerns the blood group substances, including definition of the chemical heterogeneity of preparations of mucopolysaccharides and of the terminal sugar groups determining serological specificity, the cellular phospholipids and starches A list of publications is appended

The Sarawak Museum

VOLUME 10 of *The Sarawak Museum Journal* (Nos 19–20 N S July–December 1962) maintains the high standard of previous issues and, as before, owes much to the energy and enthusiasm of its editor, Mr Tom Harrisson, who is also Government ethnologist and curator of the Sarawak Museum The theme for the volume is given as "Sarawak in a Wider Context", and though the editor himself is the main contributor, he has inspired many others to write a total of thirty papers The first section deals chiefly with the classification and typology of local archæological material, and this is followed by articles concerned with neighbouring areas Investigations in the development of various resources comprise the third section, and the volume of nearly 300 pages closes with a few notes on natural history

The Institute of Applied Science of Victoria

THE report of activities for the year ended June 30, 1962, of the Institute of Applied Science of Victoria stresses the value to-day of the science museum and records substantial progress towards building a high-performance planetarium (Pp 16 Melbourne Institute of Applied Science of Victoria, 1963) Much concentrated work was carried out in the Radiocarbon Dating Laboratory, and the erection of a neutron reactor was completed The public demand for telescope demonstrations continued to increase Besides the opening of a new north-west wing in which the setting up of displays was a major preoccupation, considerable display reorganization was made in other galleries

A Computer-based Bibliographical Retrieval and Publications System

THE computer-based bibliographical retrieval and publications system now under development at the National Library of Medicine and known as 'Medlars' is described in an article by S I Taine, which has been reprinted from the *Bulletin of the Medical Library Association* (April 1963), and also more fully in a brochure, *The Medlars Story at the National Library of Medicine*, issued by the U S Department of Health, Education and Welfare (Pp vii+74 Bethesda, Md United States Department of Health, Education and Welfare, 1963) The system will become operational early in 1964 and it is designed to improve the quality of and enlarge *Index Medicus* as well as reduce the time of preparation of the monthly edition from twenty-two to five days It will increase the average depth of indexing five-fold and almost double the number of articles handled annually, as well as facilitate the inclusion of citations from other sources and from periodicals and the efficient servicing of requests With its installation the Library expects to add monographs to the list of source material to be indexed Use of a digital computer and special composing equipment capable of providing excellent typographical quality is involved

Preparations for an International Conference

MONOGRAPH No 1, issued by the Institute of Linguists, entitled *Preparations for an International Conference* and written by A G Readett, claims, with reason, to be the most comprehensive and detailed exposition so far published of the preparatory work required to ensure the success of an international conference (Pp 20 London Institute of Linguists, 1963 10*s* 6*d*) While it covers the papers and printing arrangements as well as the conference sessions, it deals more particularly with the interpreting and translating arrangements, including equipment and the conference office and its staff Some guidance is given as to costs

Present and Future of the Fundamentals of Natural Philosophy

IN the May issue of the *British Journal for the Philosophy of Science*, Mr L L Whyte contributes an article on "Some Thoughts on Certainty in Physical Science", in which he discusses the present and future of the fundamentals of natural philosophy He is particularly concerned with what is known absolutely and uniquely about some basic properties of the universe Such knowledge is clearly apodictic (that is, true of necessity) The theme is important in view of the tendency to concentrate on uncertainty principles in our mathematical thinking Without denying the possibility of surprises, the author gives sound reasons for believing that in certain regions "the scope for discovery may be finite". Organic chemistry provides an illustration of steady logical progress for about a century, geometrical concepts have proved remarkably stable By contrast, physics has gone ahead with ever-increasing abstraction, farther and farther removed apparently from any visual image in three-dimensional Euclidean space The perfect example of something established once and for all is the existence of the 230 space-groups, the 32 classes, and the 14 Bravais lattices of the crystallographer These facts are coercive on the human mind, and the agreement between 'pure' mathematics and observation is unmistakable The velocity of light *c* in empty space, as an assertion, is not wholly acceptable, since *c* may be found to vary in high external magnetic fields Our present comprehension refers largely to static configuration future work must take account of changes.

Pleistocene Stratigraphical Chronology of Ceylon

DR P E P DERANIYAGALA, director of the National Museums in Ceylon, has recently described certain gravel beds which will prove useful in determining some of the stages of Ceylon's Pleistocene cycle of erosion (*Spolia Zeylanica*, 30, Pt 1, 1963) Such a determination is, of course, vital if the early archæological developments are to be interlocked with the geological sequence The short paper is entitled "Some Indicators in the Pleistocene Stratigraphical Chronology of Ceylon" with a page of illustrations

Aboriginal Cultural Development in Latin America

A SYMPOSIUM entitled "Relaciones de las Culturas del Nuevo Mundo" was held at the thirty-fifth International Congress of Americanists in Mexico City in August 1962, and the recently published Proceedings gives, with commendable promptitude, the revised texts of the papers delivered at it (*Smithsonian Miscellaneous Collections*, 146, No 1 *Aboriginal Cultural Development in Latin America An Interpretative Review* Publication 4517 Pp vi+148. Washington, D C Smithsonian Institution, 1963) There were ten papers, each covering one of the regions into which the area was divided, and an eleventh with the title "An Interpretative Overview" Not all of them had much to say about the relationships between the areas, hence perhaps the alteration in the published version of the title, and for various reasons, some of them outside the control of authors and editors, some were more successful than others in summing up the present state of knowledge in their own areas, but all had useful things to say, and anyone who wants to keep abreast of developments in Latin American archæology ought to read the book Great credit is due to the editors, Drs B J Meggers and C Evans, for organizing the symposium and co-ordinating the work of scholars from nine countries, and we owe a further debt to Dr Meggers for her "Overview", which includes a statement of her controversial views on the extent and importance of trans-Pacific relationships, with its suggestion of contacts between Japan and Ecuador at the surprisingly early date of the first half of the third millennium B C

Variations in the Composition of Milk

THE milk produced in the United Kingdom every day of the year is worth considerably more than £1 million, but the real worth of that milk lies in its nutritive value, and that depends on the amounts of fat, carbohydrate, protein, minerals and vitamins it contains Fortunately, in recent years there has at last been an increasing awareness of the importance of the non-fatty solids of milk in nutrition and particularly of the protein content, with the result that schemes have been or are about to be introduced in England and Wales, Scotland and Northern Ireland whereby milk is, or will be, paid for not only according to its amount or its fat content but also according to its content of total solids This should do much to maintain the nutritive value of the United Kingdom's milk supplies at a satisfactorily high level If, however, this end is to be achieved, it is important that farmers with cows the milk of which does not attain a desirable standard should be given the help and advice they need to effect an improvement Leaflet No 131 prepared by the Ministry of Agriculture of Northern Ireland discusses briefly but clearly the main factors that are known to affect the composition of milk, such as feeding, the efficiency of milking and disease, to mention but three of them (*Variations in the Composition of Milk* Pp 6 Belfast Ministry of Agriculture, 1963) Helpful advice is given on how deficiencies in butter fat content and in the content of solids-not-fat can be prevented The pamphlet as a whole is well arranged and easy to read It should be a valuable guide to those concerned with milk production

Terminology for Exchange of Gas in the Lungs

ON September 6, a meeting was held at 20 Park Crescent, London, W 1, by permission of the Medical Research

Council, at which an international group of interested persons discussed terminology of some aspects of gas exchange in the lungs, in particular the term 'diffusing capacity' The participants represented Belgium, France, Germany, Great Britain. Holland, Scandinavia, Switzerland, and the United States Dr P Hugh-Jones, Department of Medicine, King's College Hospital Medical School, London, was chairman When the term 'diffusing capacity' was originally proposed, it was considered that diffusion was the only factor determining the rate of transfer of gas between alveolar capillary blood and alveolar gas It is now known that the rate of reaction between carbon monoxide, oxygen and intracellular hæmoglobin, as well as other factors, affect the transfer rate In addition the diffusing capacity as actually measured is dependent on additional variables such as the ventilation perfusion relationship in the lungs In the light of these considerations, the majority of those present agreed that the term 'transfer factor' be substituted for 'diffusing capacity', but no definite proposal was made that this be carried out immediately Persons interested in this field of research and wishing to submit their views should write to J E Cotes, Medical Research Council Pneumoconiosis Research Unit, Llandough Hospital, Penarth, Glamorgan

Causes and Treatment of Rheumatic Disease

DURING May 29–30, 1962, the Nuffield Foundation held a small two-day conference at Ashridge College, at which scientists from various biological disciplines discussed with rheumatologists the possible nature of fundamental rheumatic processes This exchange of ideas between clinical and non-clinical research workers proved stimulating, and the Foundation believes that the report of the papers and discussion may be of value to other people A copy of the report may be obtained (without charge) by writing to the Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N W 1

International Commission on Zoological Nomenclature

NOTICE is hereby given of the possible use by the International Commission on Zoological Nomenclature of its plenary powers in connexion with the following cases, full details of which will be found in *Bulletin of Zoological Nomenclature* (20, Part 5, to be published on October 21) (1) Designation of a type-species for *Crassispira* Swainson, 1840 (Gastropoda) *Z N* (*S*) 459 (2) Validation of *Alycus* Koch, 1842 (Acari) *Z N* (*S*) 465 (3) Validation of *Natrix barbouri* Taylor, 1922 (Reptilia) *Z N* (*S*) 1559 (4) Suppression of *Conus candidus* Born, 1778 (Gastropoda) *Z N* (*S*) 1567 (5) Suppression of *Pleuronectes grohmanni* Bonaparte, 1837 (Pisces) *Z N* (*S*) 1579 (6) Validation of, and designation of a type-species for, *Diplectrona* Westwood, 1839 (Insecta, Trichoptera) *Z N* (*S*) 1580 (7) Validation of *Sceloporus torquatus* Wiegmann, 1828 (Reptilia) *Z N* (*S*) 1582 (8) Validation of *Ortholitha* Hubner, [1825] (Insecta, Lepidoptera) *Z N* (*S*) 1585 (9) Validation of *Krohnia* Langerhans, 1880 (Chaetognatha) *Z N* (*S*) 1586 (10) Suppression of nine specific names of Holothurioidea *Z N* (*S*) 1587 (11) Suppression of *Eoscorpius inflatus* Peach, 1882 (Arachnida) *Z N* (*S*) 1588 (12) Validation of *Prochilodus argenteus* Agassiz, 1829 (Pisces) *Z N* (*S*) 1590 (13) Validation of *Tinodes pusillus* McLachlan, 1862 (Insecta, Trichoptera) *Z N* (*S*) 1592 (14) Rejection of the neotype and type-locality of *Thamnophis sirtalis* (Linnaeus) (Reptilia) *Z N* (*S*) 1600 Any zoologist who wishes to comment on any of the foregoing cases should do so in writing to the Secretary, International Commission on Zoological Nomenclature, c/o British Museum (Natural History), Cromwell Road, London, S W 7, before April 21, 1964

The International Academy of Astronautics

DR CHARLES S DRAPER (United States) has been appointed president of the International Academy of Astronautics in succession to Dr F J Malina Dr Draper is head of the Department of Aeronautics and Astronautics at the Massachusetts Institute of Technology, as well as director of the Institute's Instrumentation Laboratory Prof E A Brun (France), president of the International Astronautical Federation, and Prof U S von Euler (Sweden), secretary of the Nobel Prize Committee, have been elected vice-presidents The following Academicians have been elected to the Board of Trustees of the International Academy of Astronautics Section 1—Basic Sciences, Prof A Ehmert (German Federal Republic) and Dr D F Martyn (Australia), Section 2—Engineering Sciences, Prof J M J Kooy (Holland), Dr F J Malina (United States) and Prof R Pešek (Czechoslovakia), Section 3—Life Sciences, Dr W R Lovelace II (United States) and Air Commodore W K Stewart (United Kingdom)

Announcements

PROF LINUS PAULING, of the California Institute of Technology, has been awarded the Nobel Peace Prize for 1962 In 1954 Prof Pauling was awarded the Nobel Prize for Chemistry (see *Nature*, 174, 907, 1954) He is a foreign member of the Royal Society

THE Right Hon Lord Franks, Provost of Worcester College, Oxford, and former chairman of Lloyds Bank, and Prof R H S Thompson, professor of chemical pathology, Guy's Hospital Medical School, have been appointed additional trustees of the Wellcome Trust

A LEAFLET, *Another Kind of School*, has been issued by the National Association for Mental Health for parents of children who are not accepted for school, describing the Junior Training Centres and other openings and facilities available to enable mentally handicapped children to make the best use of their abilities (Pp 4 London Association for Mental Health, 1963 6*d*)

THE third Western National Meeting of the American Geophysical Union will be held in Boulder, Colorado, during December 26–28 Further information can be obtained from W W Kellogg, the Rand Corporation, 1700 Main Street, Santa Monica, California

THE eighth international conference on "Cosmic Rays", arranged under the joint auspices of the International Union of Pure and Applied Physics and the Department of Atomic Energy, Government of India, will be held at Jaipur during December 2–14 Further information can be obtained from Dr R R Daniel, Tata Institute of Fundamental Research, Colaba, Bombay 5

THE National Productivity Year Conference, "Productivity in the Next Five Years", will be held at Eastbourne during November 26–28 The conference is being organized by the Department of Scientific and Industrial Research and its aim is "to compare notes, to discuss future action and to provide a guide for firms and organizations in every sector of our working life" Further information can be obtained from the Secretary, British Productivity Council, Vintry House, Queen Street Place, London, E C 4.

A ONE-DAY course on "Aspects of Microbiology and Plant Protection" will be held by the Joint Biology Committee at the William Beveridge Hall, Senate House, London, W C 1, on November 16 The programme will include "Microbiology of the Air", by Dr P H Gregory, "The Migration and Dispersal of Aphids and the Dissemination of Plant Viruses", by Dr C G Johnson, "Some Chemical Aspects of Crop Protection", by Prof R L Wain, "Modern Methods of Plant Protection and the Conservation of Wildlife", by Dr N W Moore Further information and tickets can be obtained from the Joint Biology Committee, c/o the Association of Agriculture, 78 Buckingham Gate, London, S W 1

SCIENCE VERSUS TECHNOLOGY: THE BATTLE FOR BRAINS

By Prof P. V. DANCKWERTS
Department of Chemical Engineering, University of Cambridge

"THE general picture presented in this country, then, is of science sixth formers who divide the world only rather hazily into 'scientists' and 'technologists' and who attribute a quite exceptional position and prestige to doctors Scientists, they believe, are educated at universities and go on, if they are lucky, to 'do research'. research is glamorous, 'interesting', leading always to exciting new discoveries, is not really 'work', and may well make you famous Technologists, on the other hand, are educated at technical colleges, have low social prestige, are less intelligent and less well paid than scientists, and their work is often 'boring' The authors have been at some pains to identify what a boy means by saying that a job would be 'interesting' or 'boring' (the two main reasons for choice) and have come to the conclusion that in most cases the terms are simply 'grunts' of approval or disapproval and are probably related to the subject's degree of ignorance of the job concerned "

This paragraph is the crucial finding of a survey made by the Oxford University Department of Education[1] into the attitude of sixth-form scientists towards engineering and technology The survey was based on the analysis of Advanced Level of the General Certificate of Education qualifications of university entrants, questionnaires completed by 1,400 schoolboys, and interviews in schools

Those of us who are concerned with technological teaching already knew most of what the survey reveals, but there is great value in the publication of a certified, quantitative statement of the situation The evidence supports the assumption that boys in Britain tend to enter higher technological education only when they cannot get a place in faculties of pure science Applied science does not attract a fair proportion of the first-rate because of the 'public image' of the two careers current among schoolboys—an image based on a "quite unusual degree of ignorance about the nature of technology, of scientific research and of the courses open to science sixth-formers in higher education"

If we assume that more of the able boys should in fact go on to the study of technology, one of the first requirements must be to alleviate this ignorance Even factual information may not redress the balance, however, because of the hazy glamour with which science is invested in the boys' minds It seems as though it may be necessary to 'glamorize' engineering and technology in competition How far we have come since the days when Samuel Smiles' *Lives of the Engineers* was eagerly read by ambitious boys !

On the level of factual information, many attempts are being made to inform schoolboys and their masters about the true nature of the technologies as professions and subjects for higher education One hopes that the Oxford Education Department's survey itself will be widely read in schools, and that the Department's hand-book on engineering courses at the universities will be studied by headmasters, careers masters and science masters Engineering institutions and industrial concerns have taken pains to distribute literature to schools, to provide lectures, conferences and visits to university engineering departments and to industry The Duke of Edinburgh has made the point in an address to the Association for Science Education[2] on April 26 At least two films have been made in an attempt to glamorize engineering as a university and professional career There is a scheme afoot at Cambridge to invite science masters to spend a term at the University to learn about the work of the technological departments

In a recent issue of *Education*[3], Prof J T Allanson has trenchant comments to make on the general misconceptions among school-teachers and the general public about the nature of engineering Referring to its creative character, he says "Just as the painter is judged by his paintings and not by his writings on æsthetics, so the engineer is finally judged by what he makes The making involves him in the social sciences and in relations with other human beings It is not possible for a good engineer to be a 'back-room boy', nor can he believe in that curious battle between the 'two cultures' invented by Sir Charles Snow He must make an engineering unity of the physical and social sciences by the kind of intellectual and moral effort supposedly characteristic of the man who reads 'Greats' With this he must integrate imagination and personal drive, for he is not a scholar but a doer, and the more visionary and far-reaching his ideas the greater must be his struggle to achieve them against the conservatism of the orthodox"

Prof Allanson suggests that more engineers should become school-teachers He points out, too, that in the nature of things few science masters have an opportunity to practise science between graduating and beginning to teach, and that they are likely to be unaware of the type of work actually done by professional scientists—let alone that done by engineers

All these attempts to inform and to influence schoolboys and schoolmasters are no doubt having an effect, and yet they seem to make only a minor impression on the problem Schoolboys, schoolmasters, the public as a whole—even scientists—are all, in fact, under the powerful influence of the mythology of pure science Many pure scientists would share the schoolboys' views about science and technology, expressed in the first paragraph (except that they would have less respect for doctors and would know—perhaps regret—that technological subjects are taught in universities) The highest objective of university science departments is to turn out pure scientists, of whom the best will in turn get jobs in universities Pure research is held to be the supremely worth-while occupation The actual or potential applications of science do not play a perceptible part in undergraduate science courses, with the result that a school chemistry master, for example, will have learned next to nothing at his university about the chemical industry, and nothing at all about chemical engineering

The British system ensures not only that the ablest sixth-form scientists take up science rather than technology at the university, but that the ablest university science students want to take up university or pure research jobs The result is well known—too few of our best scientists going into industry, pressure for more money to be spent on pure scientific research than the country can afford, an exodus to the United States of a surplus of able young scientists who have been brought up in the tradition of pure science and are not assimilated into our economy As the Duke of Edinburgh remarked, the engineer is the means by which we are all able to enjoy the fruits of science We are not in fact fully enjoying the fruits of our science, and we shall not do so unless more of our able minds are turned towards technology during their formative period To leave it until after graduation (as sometimes suggested) is too late.

It is worth considering whether courses in 'engineering science' should form part of every undergraduate science syllabus Such courses (if well taught) might serve to light a spark of positive interest in the applications of science and to mitigate the excessively genteel attitude of graduate scientists towards technology At the same time much-increased opportunities and encouragement might be provided for changing over from science to technology in the course of a university career, this might come to be regarded as a normal route into technological studies The problem of channelling talent into technology would thereby be partly removed from the schools to the universities, where the case for technology can be properly put and the student may be expected to take a more mature and realistic view

However, both pure science departments and technological departments might find difficulties associated with changes of the kind suggested Indeed, radical changes of any kind are for many reasons difficult to introduce into established universities Perhaps there is an opportunity here for the new universities to give the rest of us a lead by breaking down the barriers between science and technology This seems to offer the best chance of balancing our scientific economy and restoring the status of the technologist to a healthy level.

RADIO STAR AND SATELLITE SCINTILLATIONS

During August 19–20 a conference was held at the Physics Department of the University of Adelaide on the subject of "Radio Star and Satellite Scintillations" The conference was held under the auspices of the Australian Institute of Physics (South Australian Division)

The conference opened with a survey by Dr B H Briggs (University of Adelaide), who showed how irregularities in the ionosphere could be detected by various methods, all concerned with effects on radio waves In the case of the *F* region, these methods include radio star scintillations, fluctuations of radio waves received from satellites, spread echoes observed in ionosphere soundings (spread-*F*), and radar back-scatter using frequencies around 20 Mc/s These phenomena are found to be correlated, which suggests that they are all due to the same irregularities in the ionization of the *F* region There is good evidence that the irregularities are elongated, and 'field aligned', so that their longer dimension lies along the direction of the Earth's magnetic field They occur at heights from 200 km upwards, recent 'topside soundings' by the *Alouette* satellite (*Nature*, 197, 636, 1963) show that on some occasions they exist at heights up to at least 1,000 km

When radio stars are observed at low angles of elevation, irregularities lower down, in the *E* region, are found to be important This might be expected, since the increase in thickness along the line of sight is greater for a layer of irregularities at a low height than for a layer at a great height, so that irregularities low down become relatively more important Irregularities in the *E* region and below can also be detected by several other methods, including the fading of reflected waves, observations of 'sporadic *E*' echoes on ionograms, and the investigation of weak irregularities below the *E* region by the scattering of radio waves at oblique or vertical incidence A remarkable feature of the irregularities revealed by the latter technique is their tendency to occur in stratified layers with a vertical separation of 10 km

After discussing these experimental observations, Dr Briggs turned to the vexed question of the origin of the irregularities In the *E* region and below it is generally agreed that the irregularities are due to irregular air motions, though the relative importance of turbulence, random wave motions, and vertical shears in the horizontal wind is still uncertain Higher up, in the *F* region, these motions are damped out due to the high kinematic viscosity, and other mechanisms must be found The irregularities in the *F* region do, indeed, seem to be a separate phenomenon, as is shown by their large intensity (deviations of electron density of ± 50 per cent are common) and their tendency to occur mainly at night Two early theories, which accounted in a simple way for the occurrence at night, were the accretion theory and the atmospheric tail theory In the former the irregularities were thought to be produced by material falling into the Sun by gravitational attraction, and intercepted by the Earth. In the latter an atmospheric 'tail' was postulated, pointing away from the Sun and produced either by radiation pressure or the effect of the solar wind Later theories have attributed the irregularities to hydromagnetic waves entering the atmosphere, to particle streams associated with the Van Allen belts or the aurora, to instability of an ionospheric layer moving vertically under the action of an electrodynamic drift, and to irregular electric fields produced lower down in the *E* region Dr Briggs suggested that the observations should, where possible, be discussed in relation to these theories, in order to attempt to eliminate some of them

Dr J W Warwick (University of Colorado and High Altitude Observatory, Boulder, Colorado) then described observations of radio star scintillations obtained with a swept-frequency interferometer These observations showed that amplitude scintillations had a similar form over the range 7–41 Mc/s Also, fluctuations in position of the source could be determined and these often showed systematic trends as a function of frequency Dr Warwick showed that these could be explained by geometrical optics if a succession of 'lenses', focusing approximately at ground-level, were assumed to exist in the ionosphere On some occasions the observations could be explained in terms of a wave-like structure moving with a velocity of about 50 m/sec

Miss E M Matthew (University of Queensland) described some observations of radar echoes from field-aligned irregularities in the *F* region made at Brisbane The echoes were related to variations in the outer Van Allen belt and to various ionogram anomalies The northward speed of patches of irregularities could be observed, and a sudden increase of speed was interpreted as arising from some form of impact on the magnetosphere

Dr G G Bowman (University of Queensland) described investigations of the occurrence of spread-*F* echoes at mid-latitude stations, and these seem to show that spread-*F* is most prevalent when the air density in the upper *F* region is low Dr B H Briggs (University of Adelaide) described observations of radio star scintillations and spread-*F* echoes made in England At sunspot maximum the irregularities increase in intensity but occur mainly above the level of maximum ionization of the *F* region and do not, therefore, produce spread-*F* echoes on ionograms Thus the opposite trends of scintillation occurrence and spread-*F* occurrence with the solar cycle can be reconciled The results appear to conflict with the 'instability' theory of Dr D F Martyn, according to which irregularities would form mainly on the underside of the *F* region

Dr J D Whitehead (University of Queensland) then gave a critical survey of the theories of formation of irregularities in the F region He pointed out that, for hydromagnetic waves, the percentage fluctuation of electron density is equal to the percentage fluctuation of magnetic field, and this appears to demand unreasonably large amplitudes for the waves The instability theory was criticized on the grounds that the observed vertical motions of the F region were not those required by the theory Dr Whitehead suggested that the irregularities were produced either by air movements associated with internal gravity waves, or by irregular electric fields, and the theories of formation of irregularities by these mechanisms were considered Dr Whitehead stressed the need for more detailed measurements of the sizes and shapes of the irregularities so that the predictions of the theories could be tested

On the second day of the conference, satellite scintillations were discussed Unlike a radio star, a satellite sweeps rapidly across the sky from horizon to horizon, and so the method is particularly valuable for examining the geographical distribution of irregularities, especially if observations from several stations are combined Dr G H Munro (Radio Research Board, Sydney) described observations of this type, in which transmissions on 20 Mc/s from the satellites *Nora Alice I* and *II* were used The results showed that irregularities tend to occur in patches which become more frequent, and larger, at higher latitudes The patches appear to be elongated east–west and may stretch in this direction for 1,000 miles or more From measurements of the times of onset of scintillations at spaced stations the heights of the patches may also be determined

Mr. I A Parkin (University of Adelaide) discussed the theory of the diffraction process which links the irregularities in the ionosphere to the pattern of amplitude and phase which is observed over the ground He considered both a source at infinity and at a finite distance If detailed deductions about the sizes and shapes of the irregularities are to be made, it is necessary to use frequencies such that the fluctuation of phase across the emerging wavefront is less than one radian It is then possible to relate the auto-correlation function of amplitude measured on the ground to the auto-correlation function of the irregular medium Mr Parkin also pointed out that at a given distance from the irregularities certain Fourier components should be absent in the amplitude pattern, and so measurements of the power spectrum of the pattern may enable the height of the irregularities to be determined Some discussion of the relation between the diffraction approach and the method of geometrical optics followed Mr Parkin's paper, and it was agreed that in principle the diffraction method is always valid, but in practice it is most useful when the phase deviation is small, while the method of geometrical optics is useful when the phase deviation is large

Attention then turned to irregularities at lower heights Dr R G Roper (University of Adelaide) described measurements of winds and turbulence in the height range 70–110 km, and Dr J D Whitehead (University of Queensland) discussed the formation of sporadic E which, at temperate latitudes, he considered to be produced by vertical shears in the horizontal wind However, the irregular wind shears described by Dr Roper had the greatest magnitude at the equinoxes, and this does not agree with the occurrence of sporadic E, which is most prevalent in summer Dr Whitehead also discussed the formation of equatorial sporadic E, which he suggested was due to irregularities formed by sound waves

The conference concluded with two papers of a more technical nature Dr L H Heisler (Radio Research Board, Sydney) described equipment for the investigation of the variation with frequency of the amplitude of radio waves reflected from the ionosphere, and Dr J D Whitehead (University of Queensland) described a proposed method for measuring with increased precision the virtual height of reflexion

During the conference the opportunity was taken to discuss observations of the forthcoming *S66 Beacon* satellite which are being planned in Australia and New Zealand The general feeling was that much more work needs to be done before the mode of formation of ionospheric irregularities is properly understood, and that intensive observations using the *Beacon* satellite are likely to make a valuable contribution towards this end

B H BRIGGS

OXIDATIVE PHOSPHORYLATION AND RELATED PROCESSES

THE Medical Sciences Club of South Australia and the Australian Biochemical Society (South Australian Branch) held a symposium on "Oxidative Phosphorylation and Related Processes" in the Biochemistry Department, University of Adelaide, during June 14–15

Prof E C Slater (Amsterdam) opened the symposium with a review of present-day theories on the formation of adenosine triphosphate in mitochondria He contrasted Mitchell's theory that this process is the reversal of hydrolysis of adenosine triphosphate by an anisotropic adenosine triphosphatase to the more widely accepted view that adenosine triphosphate is produced by reactions involving a number of specific intermediates formed at several different 'sites' in the sequence of oxidation-reduction catalysts in mitochondria Much of the evidence for such intermediates has been obtained in experiments with oligomycin, which prevents formation of adenosine triphosphate but does not inhibit other reactions such as the reduction of nicotinamide-adenine dinucleotide by succinate, for thermodynamic reasons, this reduction must be coupled to exergonic processes such as the decomposition of compounds like the proposed intermediates However, these investigations do not allow a final choice between Mitchell's theory and that preferred by Slater Chance and others involving specific intermediates of the type often formulated as $A \sim C$ It was pointed out in discussion that the existence of adenosine triphosphate and adenosine diphosphate in a region of the mitochondrion not accessible to oligomycin would invalidate certain conclusions drawn from experiments with this inhibitor

Prof J S Sturtevant (Yale) described kinetic investigations of the interaction of cytochrome b_2 (the L(+)-lactate dehydrogenase of yeast) with lactate and ferricyanide Using a stopped-flow spectrophotometer at a number of wave-lengths, evidence was obtained which indicated a preliminary reduction of flavin mononucleotide, an intra-molecular transfer of electrons to protohæm, and interaction of both prosthetic groups of this flavohæmoprotein with ferricyanide The results support earlier suggestions by Morton, who found equimolar quantities of these prosthetic groups in the enzyme and proposed a mechanism involving intra-molecular transfer of electrons from flavin to hæm The need to find if cytochrome b_2 is a constituent of yeast mitochondria was considered in the general discussion following these papers Clearly a single flavohæmoprotein is a potential model for the more complex flavin-hæm systems of the whole mitochondrion

Dr M R Atkinson (Adelaide) reviewed recent evidence for phosphorylated and unphosphorylated intermediates of oxidative phosphorylation and described electrophoretic investigations (with urea-starch gels or on paper after tryptic hydrolysis) of the radioactive products obtained on exposure of mitochondria and mitochondrial extracts to radioactive orthophosphate He proposed a model for adenosine triphosphate synthesis in a concerted reaction with adenosine diphosphate, orthophosphate and an activated derivative of cytochrome *c* formed through acylation of the histidyl residue on the hæm iron by the adjacent glutamyl side-chain

Dr A M Snoswell (New South Wales) described experiments in which reduction of nicotinamide-adenine dinucleotide by succinate in mitochondria from rabbit heart was coupled to electron transfer from succinate or from tetramethylphenylenediamine to oxygen through cytochrome *c* and cytochrome oxidase The resistance of the coupled reductions to oligomycin was interpreted as evidence for activated intermediates other than adenosine triphosphate, which permit reduction of nicotinamide-adenine dinucleotide by compounds of higher oxidation-reduction potential Dr M L Birt (Melbourne) described related experiments with liver mitochondria prepared in a Krebs buffer in which reduction of the co-enzyme by succinate was inhibited by dinitrophenol but was not entirely inhibited by anaerobic conditions or by antimycin *A* and amytal The relative importance of reduction through enzymes such as malate dehydrogenase and reduction of co-enzyme through reversal of the respiratory chain was discussed

Prof R N Robertson (Adelaide) reviewed recent investigations of the relationship of oxidative phosphorylation to the active transport of ions against an electrochemical gradient Active transport need not be coupled to hydrolysis of adenosine triphosphate, but transport of ions or phosphorylation of adenosine diphosphate may be alternative consequences of the oxidative generation of compounds of the $A \sim B$ type or the oxidative separation of positive and negative charge, as envisaged by Mitchell Dr J Charnock (Adelaide) described experiments on an adenosine triphosphatase from the microsomal fraction of kidney, this enzyme requires sodium and potassium ions for full activity and is inhibited by ouabain Dr Charnock discussed the evidence that a phosphoprotein intermediate is involved in the action of the enzyme and that the phosphoprotein might carry cations across membranes Dr B Hetzel (Adelaide) discussed the uncoupling of oxidative phosphorylation by thyroxine and triiodothyronine and reviewed evidence that this process was involved in the physiological action of these compounds

In his concluding remarks, Prof R K Morton (Adelaide), who arranged the meeting, emphasized the need for caution in interpreting the results of investigations with phosphorylated compounds derived from mitochondria, these might differ from the true intermediates, just as the isolation of phosphorylated enzymes does not prove the involvement of these compounds in enzymatic phosphoryl transfer

The cryptic nature of many publications on oxidative phosphorylation caused much good-humoured but frustrated comment, and most participants looked forward to the publication of experimental details which will permit more detailed examination of many recent claims in this remarkably active field of scientific investigation

M R Atkinson
[The late] R K Morton

ORGANIC MATTER AND SOIL PRODUCTIVITY

IT has commonly been accepted that farmyard manure is desirable or even essential to maintain or improve soil fertility, because it exerts a beneficial effect on the physical condition of practically all mineral soils and steadily supplies plant nutrients as it decomposes Market gardeners have relied on stable and byre manures from the nearest towns and farmers in arable areas have kept cattle over winter to provide manure for the potato and root crops in the rotation Most growers in fact have been so convinced of the value of regular additions of organic waste material to the soil that, in face of declining supplies of farmyard manure, they have adopted various methods of green manuring or of composting or even of bringing in peat In effect, a normal dressing of 10–15 tons of farmyard manure amounts to some 2 tons of organic matter per acre or 0 2 per cent in the top 9 in of soil This amount is barely measurable by sampling and analysis It is substantially the same as the annual leaf litter in woodland, it is not much more than the amount in the stubble and roots of a cereal crop, it is much less than what is incorporated in the soil by ploughing in grass turf Nevertheless, there remains the conviction that on many types of soil fresh organic matter confers a benefit that is not obtained from plant nutrients alone

It is practically impossible to make a strict comparison of organic manures with inorganic fertilizers since the former contain nutrients that become available to the plant over a more or less prolonged period and, at the same time, modify the soil in a manner that affects all the factors like æration, water movement and biological activity that play a part in crop development There is undoubtedly evidence that the crop responses to the total nutrients in farmyard manure are very much less than those obtained from the same amounts of nutrients applied as soluble fertilizers There have also been recent assessments from field experiments which indicate that the merit of farmyard manure is to be attributed almost solely to its nutrient content But the fact remains that on some soils it is not possible to produce maximum crops, with or without fertilizers, unless farmyard manure has been used It is not surprising, therefore, that investigators have been searching for more precise information on the effects of additions of organic matter to the soil Is it possible, for example, that organic matter may affect the availability of nutrients to the plant, or may produce derivatives that influence plant growth either directly, through absorption by the roots, or indirectly, by controlling the incidence of disease?

These matters are the subject of a well-documented review by D C Whitehead entitled "Some Aspects of the Influence of Organic Matter on Soil Fertility" in a recent issue of *Soils and Fertilizers* (26, No 4, Commonwealth Bureau of Soils, 1963) He discusses the question of soil nitrogen released from organic residues or fixed by symbiotic or free-living organisms, of the ability of organic acids to release insoluble forms of phosphorus and potassium, and certain trace elements, from the soil particles He also directs attention to the absorption by the roots of organic molecules that could influence plant metabolism—this covers such substances as amino-acids, vitamins, phenolic compounds and auxins—and to the ability of organic matter to favour saprophytic organisms rather than parasitic, there are also various decomposition products that are toxic to fungi There is much contradictory evidence and obviously a need for further work to establish the significance of these compounds They are known to be produced, but the quantities concerned and the probable interactions are still largely speculative

Closely related to this review is an article on "The Biological Nature of Soil Productivity", by G V Jacks (26, No 3, 1963) This is designed to show how fertility is dependent on bio-physical rather than on physico-chemical changes in the soil It is the action of plants that converts radiant energy into energy for animals and micro-organisms, which in turn produce a structure out of structureless material. The cementing together of individual soil particles to form aggregates is essentially a physico-chemical process, but the building of the aggregates into a stable granular structure is dependent on the activity of living organisms. The agencies are varied and include organic acids and polysaccharides, bacterial gums and fungal hyphæ and mycelia, all stages in the decomposition of organic residues. There is also the action of plant roots in binding soil particles and giving rise to a porous crumb, and of earthworms in not only producing casts of mineral-organic aggregates but also of making channels for æration and water movement. Indeed, much of the organic matter in the soil consists of excrement from soil fauna.

The soil medium becomes, therefore, a climax association of plant and fauna with a definite level of productivity. This productivity can be enhanced by man, through the physical and chemical modifications brought about by cultivation and manuring; but it can also be reduced by destroying the environment built by natural agencies. It is possible to grow healthy plants without soil, but that is a specialized business; so long as soil is used the grower must endeavour to preserve or improve its structure.

RESOURCES OF PETROLEUM: HOW MUCH OIL?

EVER since petroleum became a world wide commercial proposition and the industry thus firmly established, the phenomenal and rapid developments of the world's oilfields with concomitant expansion of production, especially in the United States since the turn of the century, have periodically posed these questions: How long will oil resources last, is production outstripping supply? Economists, perhaps even more vociferous than technologists, have from time to time uttered dire warnings that the day may come when oil will become scarce; that other sources of fuel and energy must be harnessed to make up any deficiences in supply. For example, there was a memorable occasion in 1923 when it was thought that the United States had passed peak production; thenceforward a downward trend was predicted, with some 15–20 years ahead before calamity overtook the industry. In 1925 I myself stated: "Petroleum production has hitherto been, still is, and for some time is likely to be entirely dominated by the output from the United States. With the average figure of 15 per cent as representative of the rest of the world's contribution to total production, we have probably not got a real assessment of the potentialities of other countries, since their economic activities must largely be subservient to the greater influence. In other words, it is quite conceivable that in the event of material decline in United States output, more could be made good by external oil production than appears at first glance. Factors tending to this end include increased geological exploration, increased production from shut-in reserves, and a higher technique in petroleum engineering". "The possibilities of the world's 'peak' of production of oil having been passed in 1923 have been shown to be open to considerable doubt" (*Mining Magazine*, November 1925).

Subsequent events have more than justified that opinion and the present position is adequate answer to pessimistic prophecies of the years between. It is a fact that one-third of the world's proved reserves of petroleum to-day are in oilfields that were literally unknown, probably still less imagined, before 1950. This fact, its significance and the theme "How Much Oil" are the substance of an article by Mr. M. J. Rathbone, chairman of the Standard Oil Co. (New Jersey), in a recent issue of the house-journal, *The Lamp* (45, No. 2; 1963). Therein he speaks with authority and makes some cogent comments on the present world oil situation. A nice distinction is rightly drawn between 'reserves' and 'resources', two words often loosely applied and economically misleading out of proper context. He comments, "If you read that the world's proved oil reserves are estimated at 300 billion barrels, that oil is being consumed at the rate of nearly 9 billion barrels a year, and that this rate of consumption will probably double by 1980—you may well wonder how soon we will reach the bottom of the barrel . . . that figure of 300 billion barrels of 'proved reserves' . . . is one of our most misunderstood statistics. It does not measure the world's true oil resources at all. It is no more than an estimate of the oil we can obtain from fields already discovered, using present recovery techniques. Despite rising world consumption rates, 'proved reserve' figures go up every year". The fact is that petroleum to-day is being discovered faster than it can be used. More oil is being obtained from old fields, new fields are being proved simultaneously. Submarine oilfields, often in extension of known continental developments, have to be reckoned with. One example is the shelf region off the Louisiana coast, opened to exploration only last year and, according to Mr. Rathbone, now proved to contain billions of barrels of oil. Another case he cites is that of Libya, where six years ago there were no known oil reserves, but to-day considered to be a major source of supply.

Thus, reserves are proved on a very large scale. Resources, that is, extensive land-areas of the world potentially oil-bearing but as yet untouched by the drill, remain to be explored quite apart from under-water researches. In view of the drastic readjustment of our ideas concerning geographical distribution of favourable oil-pool structures, occasioned by the discoveries of the past decade, the location of oil and gas-fields in regions where twenty or thirty years ago no hopes whatever were entertained, then we may agree with Mr. Rathbone's contention that ". . . we have solid grounds for reassurance that petroleum resources are abundant relative to foreseeable demand".

MONOMER – DIMER FORMS OF BENCE JONES PROTEINS

By Dr. GEORGE M. BERNIER and Prof. FRANK W. PUTNAM

Department of Biochemistry, College of Medicine, University of Florida, Gainesville

BENCE JONES proteins, the abnormal biosynthetic products excreted in the urine of myeloma patients, are defined as low-molecular-weight proteins, antigenically and chemically related to γ-globulin[1,2], which precipitate when heated to temperatures near 50° C, dissolve on boiling, and reprecipitate on cooling[3]. Isotopic investigations have shown that this protein probably represents an aberrant synthetic portion of γ-globulin[4]. Edelman and

Gally[5] have presented evidence that L-chains obtained by reductive cleavage of 7 *S* myeloma globulins are closely related to, if not identical with, the Bence Jones protein from the same individual. These L-chains have a molecular weight of approximately 20,000, and these authors postulate that the usual 3·5 *S* Bence Jones protein exists as a dimer of L-chains. Although most Bence Jones proteins have sedimentation coefficients of 3·5 *S*, some do occur naturally as 1·8–2·5 *S* units[6], and earlier work by Putnam and Stelos showed that 3·5 *S* Bence Jones proteins dissociate into smaller components at *p*H 4 (ref. 7). In the present investigation, the existence of polymerism in several Bence Jones proteins has been demonstrated. The results are illustrated by a description of chemically and antigenically identical monomer and dimer forms of one such protein.

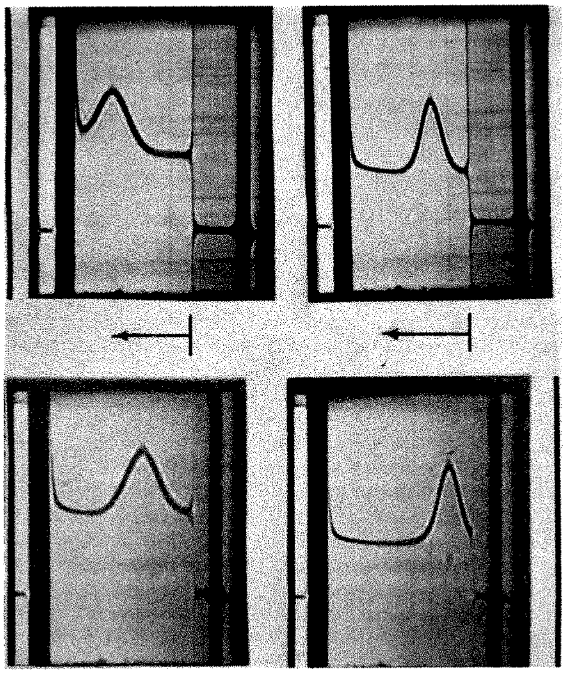

Fig. 1. Ultracentrifuge diagrams of monomer and dimer in 0·15 M sodium chloride, 20° C, 59,780 r.p.m. Above, dimer; below, monomer. In each case the pictures were taken 64 and 128 min after start of run. The arrow shows the direction of migration; the tail of the arrow indicates the meniscus

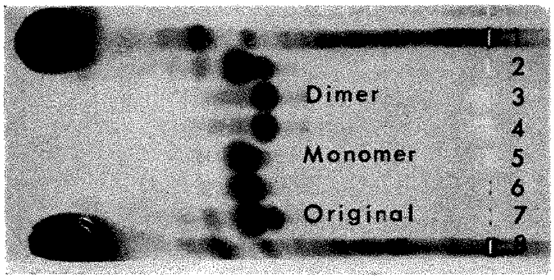

Fig. 2. Starch gel electrophoresis at *p*H 8·65, discontinuous buffer system, of normal human serum (1 + 8), original Bence Jones (*Ag*) (2 + 7), dimer (3 + 4), and monomer (5 + 6)

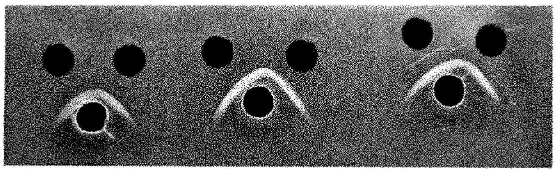

Fig. 3. Ouchterlony double diffusion in agar. The top left well in each triangle is monomer, and the top right well is dimer. The rabbit antisera are anti-normal human γ-globulin (left), anti-type I Bence Jones protein (centre), and anti-type I macroglobulin (right). The reactions are those of identity except that the monomer has precipitated closer to the antiserum well in each case. The same reaction was given by specific antisera prepared against the monomer

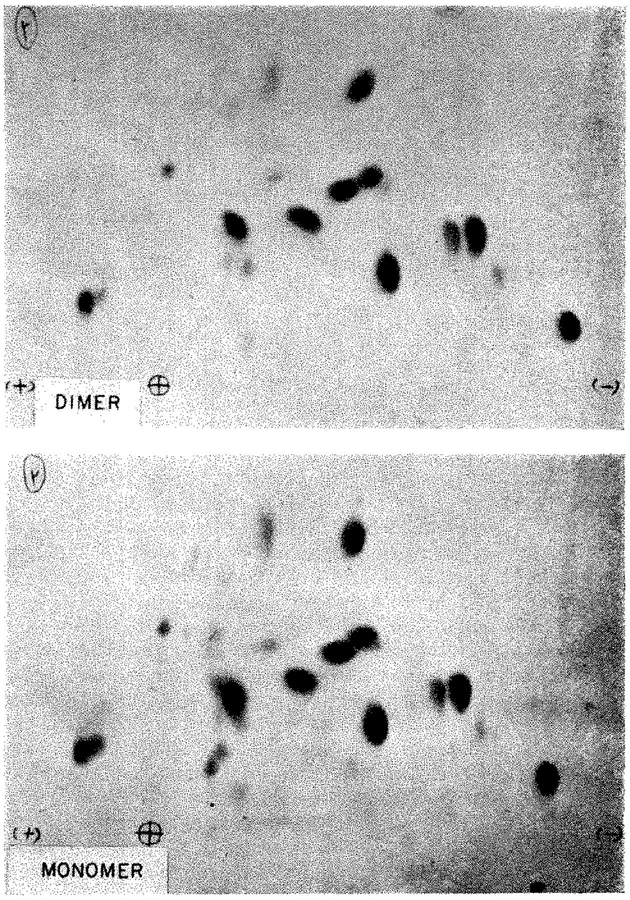

Fig. 4. Maps of tryptic peptides of dimer (above) and monomer (below). The samples were chromatographed for 20 h in butanol/acetic acid/water (4 : 1 : 5) and electrophoresed at *p*H 3·7, pyridine/acetic acid/water (1 : 10 : 289)

This Bence Jones protein was obtained by ammonium sulphate precipitation from the urine of a myeloma patient (*Ag*). Although more than 90 per cent homogeneous in Tiselius electrophoresis, this protein showed characteristic multiple banding in vertical starch-gel electrophoresis with a discontinuous buffer system of *p*H 8·65. It was chromatographed on the Beckman Model 130 Spectrochrom, using DEAE 'Sephadex (*A*-50)' with starting buffer *p*H 8·0, 0·02 M potassium phosphate and limiting buffer *p*H 8·0, 0·02 M potassium phosphate–1·0 M sodium chloride. Fractions so obtained were further chromatographed on 'Sephadex *G*-100'. A number of components were isolated, each of which migrated largely as a single band in starch-gel electrophoresis.

Two of the isolated fractions which were obtained in appreciable amounts had sedimentation coefficients in saline of 3·6 *S* and 2·4 *S* respectively (Fig. 1). The two fractions differed in starch-gel mobility (Fig. 2), but were identical by immunological testing (Fig. 3), peptide mapping (Fig. 4), and thermal solubility curves. Total amino-acid analyses (Table 1) were virtually identical. Significantly, methionine, an amino-acid often absent in Bence Jones proteins, was present as one mole per 21,900 g of the smaller protein, and as two moles per 42,400 of the larger. Half-cystine was present as four residues per monomer. There are 12 lysine and 6 arginine residues present in the monomer. From the known specificity of

Table 1. AMINO-ACID COMPOSITION OF MONOMER AND DIMER

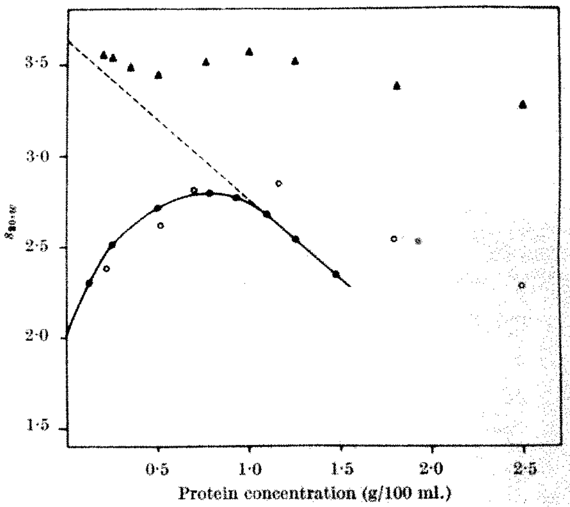

Fig. 5. Concentration dependence of $s_{20,w}$ of monomer at *p*H 6·8 and *p*H 8·6, and of another Bence Jones (*Sh*) at *p*H 6·8. All buffers were 0·1 M. ▲, Bence Jones (*Sh*) *p*H 6·8; ○, Bence Jones (*Ag* monomer) *p*H 8·6; ●, Bence Jones (*Ag* monomer) *p*H 6·8

trypsin, 19 tryptic peptides would be anticipated. The peptide maps shown here each contain some 20 peptides. Twelve of these have been isolated and their composition determined. The presence of slightly less than 2 moles of *N*-terminal aspartic acid per 44,000 g of this protein has earlier been reported[8].

Further proof of dimerization was established by the curvilinear concentration dependence of $s_{20,w}$ exhibited by the monomer, analogous to the behaviour of α-chymotrypsinogen[9]. Fig. 5 contrasts the concentration dependence of the *Ag* monomer (antigenic type I) and that of another Bence Jones protein (*Sh*) of antigenic type II. In our experience all Bence Jones proteins having an $s_{20,w}$ of 2·5–3 *S* at neutral *p*H have been of antigenic type I, but it is premature to conclude that this type dissociates more readily than type II.

These findings give further evidence that the usual 3·5 *S* Bence Jones proteins exist as dimers of two identical polypeptide chains which have molecular weights of approximately 22,000. It makes more plausible the presence of a 22,000 molecular weight Bence Jones-like polypeptide chain in the papain-produced 3·5 *S* 'slow' (*S*) fragment of myeloma globulin, about half of which appears to consist of Bence Jones protein by peptide mapping. At least two analogous (Bence Jones-like) polypeptide chains must occur in normal human γ-globulin though, to be sure, these may vary in structure among different antibodies just as the Bence Jones proteins of individual patients differ[10].

ORIGIN OF OSTEOCLASTS FROM THE FUSION OF PHAGOCYTES

An investigation of the sequelæ of partial ischæmia by the intra-arterial injection of particulate suspensions of bone charcoal in the nutrient arteries of femurs in growing rabbits reveals evidence in support of the view that osteoclasts arise by fusion of mononuclear wandering cells (histiocytes, macrophages). Our findings support the idea of Hancox[1] that "it is in the histiocytic state alone that cells (whose origin is then irrelevant) are capable of fusing to form osteoclasts".

Our experiment involves the injection of 8–15 c.c. of a 2 per cent suspension of dextran sulphate and bone charcoal in physiological saline into the nutrient artery of the right femur in 43 8-week-old New Zealand white rabbits. The contralateral femur was injected with isotonic saline and served as the control. The treated animals were killed immediately after the injection and serially up to 240 days. Both femurs were fixed in 10 per cent neutral formalin, decalcified, embedded in celloidin, sectioned, and stained in hæmatoxylin and eosin.

Up to 4 days post-injection, the bulk of the charcoal was found to be localized in the vascular channels (arterioles and capillaries) of the femoral metaphysis. Some isolated macrophages in the vicinity of the vessels laden with charcoal contained a few finely dispersed charcoal particles less than a micron in size. At 5 days post-injection, a larger population of macrophages as well as some spindle-shaped cells contained the charcoal (Fig. 1). It was difficult to differentiate histologically some of the spindle cells from a reticular cell. These cells could best be described as phagocytic reticular cells. Although the free macrophages surrounding osteoclasts were heavily burdened with charcoal, the osteoclasts were free of particulate material. This led us to conclude that the osteoclasts were incapable of phagocytizing the charcoal.

At 12 days post-injection, the particulate material was found in macrophages, spindle cells (phagocytic reticular cells), and a few osteoclasts. At this time only a few finely dispersed charcoal particles were found in occasional osteoclasts, while between 15 and 35 days there was a progressive increase in the number of osteoclasts and spindle cells laden with charcoal (Figs. 1 and 2). The

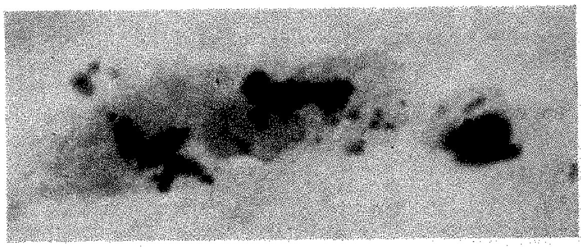

Fig. 1. Spindle-shaped cell (probably a phagocytic reticular cell) with particulate charcoal within its cytoplasm. (× 900)

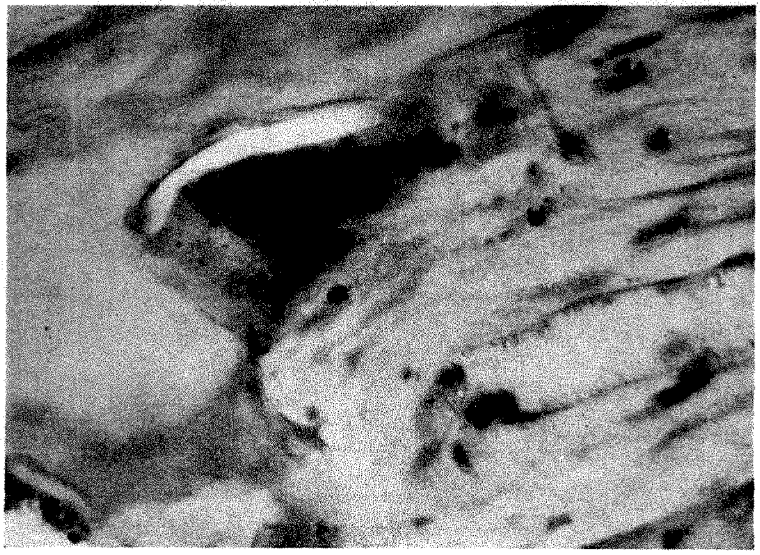

Fig. 2. Examples of osteoclast formed by the fusion of macrophages, containing charcoal in part of its cytoplasm. (× 800)

distribution of the charcoal in the osteoclasts was uneven (Figs. 2 and 3). These charcoal-laden osteoclasts were observed to arise from the coalescence of macrophages (histiocytes) containing the particulates. It should be emphasized again that when the charcoal was phagocytized by the macrophage, the particulate was absent in osteoclasts. At no time did we observe any charcoal in osteoblasts.

It was difficult to determine whether the macrophages transformed into spindle (reticular) cells. The difficulty arose because they both contained charcoal at the same time. It is generally agreed that the phagocytic reticular cell (free macrophage[2]) is capable of phagocytosis. A huge population of charcoal-laden osteoclasts and spindle cells were observed between 15 and 30 days. The appearance of these cells was related to massive osteoclasis of the femoral metaphysis as a consequence of the partial ischæmia. A more detailed description of these dynamic events will be reported elsewhere.

Recent contributions to the question concerning the origin of the osteoclast have been reported in the investigations of the inter-relationships of the cells of bone using the technique of tritiated-thymidine autoradiography. These investigations have re-affirmed that osteoclasts are formed by coalescing uninucleated precursors. However, the same investigations have led to different conclusions that the precursors are osteoblasts[3] or osteoprogenitor (mesenchymal, spindle, reticular) cells[4,5]. Our findings support the view that the osteoblasts are not the prerequisite cells for the formation of osteoclasts. Many workers believed that the osteoclast arose by the fusion of mononuclear wandering cells (histiocytes, macrophage). Hancox cited these investigators and their contributions in his excellent review on osteoclasts[1].

To sum up, we have evidence to support Hancox's hypothesis[1] that the cells in the phagocytic (histiocytic) state do fuse to form osteoclasts. Therefore, the cells of bone marrow possessing the ability to phagocytize and mobility are capable of coalescing to form osteoclasts.

[5] Young, R. W., *J. Cell Biol.*, **14**, 357 (1962).

IN 1873 Kölliker[1] proposed that osteoclasts were formed by the fusion of osteoblasts. Since then many alternative claims have been made. These have included the origin of osteoclasts by fusion of fibroblasts, reticulum cells, bone cells with cartilage cells liberated from skeletal matrix, histiocytes, macrophages, monocytes, lymphocytes and liberated chondrocytes. Unfortunately these investigations have been generally conducted at the metaphyseal regions of long bones which contain numerous cell lines. This is a serious drawback in that many cells cannot be properly distinguished, for example, spindle cells, reticular cells, pre-osteoblasts, etc.

In order to avoid this difficulty and to increase the specificity of the observations, investigations were conducted at the periosteum using tritiated-thymidine (^{3}HTDR) autoradiography[2-4]. At the periosteum the origin of the osteoclast can only be attributed to pre-osteoblasts and/or osteoblasts, since these cells exclusively make up the osteogenic layer. The specific results which are achieved with the use of ^{3}HTDR have led us to the unquestionable evidence that osteoclasts are formed by fusion of osteoblasts and possibly pre-osteoblasts as well[4]. Young's ^{3}HTDR investigations[5] on ribs and tibiæ which followed presented good evidence that pre-osteoblasts were equally involved. Recently, excellent ^{3}HTDR evidence has been presented for the origin of osteoclasts from fusion of mononuclear leucocytes in newt limbs[6].

It appears that not all osteoclasts are produced by the same precursors. In periosteum, they are formed from osteo-

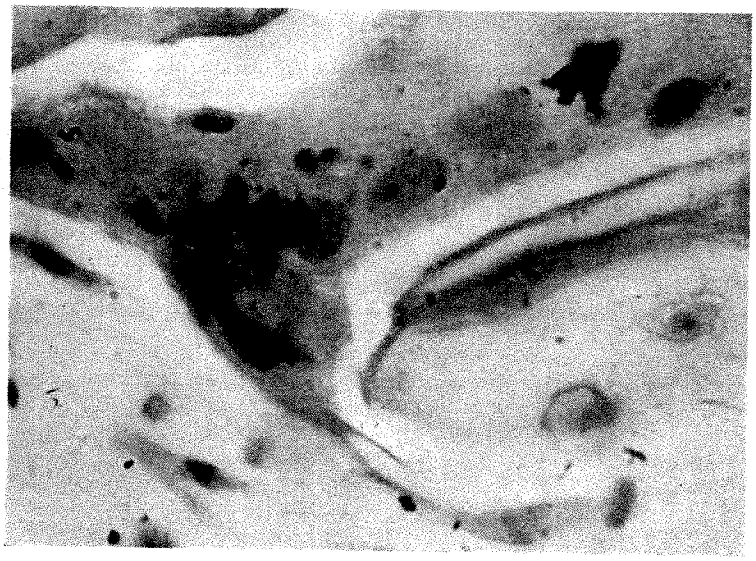

Fig. 3. An osteoclast surrounding a bone spicule with uneven distribution of charcoal particles within the cell. (× 800)

blasts and pre-osteoblasts, at the metaphyseal region other cells claimed to be precursors may well be. However, interpretations at metaphyseal sites are extremely difficult to make

Jee and Nolan have claimed that histiocytes are the precursors of osteoclasts on the basis of observations made on tissues of animals previously injected with charcoal particles Within the first 4 days charcoal was seen almost exclusively in vascular channels Not until the 12th day was there evidence of an occasional osteoclast containing charcoal, whereas, from the 5th day on, macrophages in the vicinity of osteoclasts were heavily burdened with charcoal

In ^{3}HTDR investigations, Young[5] saw labelled osteoclasts within 9 h Kember[7] observed osteoclasts at the metaphysis by 24 h We[4] have observed them at the metaphysis in 18 h and 36 h at the periosteum If histiocytes were the precursors of osteoclasts, Why was charcoal not observed in osteoclasts earlier? Why did it take a long period of 12 days for them to contain charcoal? Osteoblasts do not phagocytize charcoal and if they were to participate in osteoclast formation at the metaphysis, the results would not be different On the other hand, it is well-known that osteoclasts themselves are phagocytic However, this does not mean that the phagocytic property is unlimited or unspecific Jee and Nolan's work shows clearly that osteoclasts do not normally phagocytize charcoal particles, but does not discount the possibility of active phagocytosis by osteoclasts of cells which may have lost their ability to cope with life after gorging themselves with charcoal particles This could easily lead to the conclusion that histiocytes are the precursors of osteoclasts. However, this seems highly unlikely since 12 days were required before several charcoal containing osteoclasts were observed.

At present it appears that several cellular types are capable of fusion to form osteoclasts, perhaps also histiocytes In view of the extremely long period which was required to find charcoal containing osteoclasts in adversity to several and repeated ^{3}HTDR investigations, where labelled osteoclasts were found after 9 or more hours, it is believed that, contrary to the conclusions of Jee and Nolan, their investigation shows that histiocytes are not the major contributors to osteoclast formation and may well not be involved at all.

SITE OF SYNTHESIS OF CYTOPLASMIC RIBONUCLEIC ACID

By PROF HENRY HARRIS and L F. LaCOUR

Sir William Dunn School of Pathology, Oxford, and Department of Cell Biology, John Innes Institute, Bayfordbury, Hertford

ALTHOUGH the question has been investigated extensively over the past decade, in both animal and plant cells, it has not yet been decided whether RNA is synthesized in the cytoplasm of the cell or whether synthesis of RNA occurs only in the nucleus Numerous chemical[1,2] and autoradiographic[3–8] experiments have demonstrated that when cells are exposed to a radioactive RNA precursor the RNA in the nucleus becomes labelled more rapidly than the RNA in the cytoplasm When labelled cells are transferred to non-radioactive medium the amount of radioactivity in the nuclear RNA falls and the amount in the cytoplasmic RNA rises It has been claimed that the disappearance of radioactivity from the nuclear RNA and its appearance in the cytoplasmic RNA represent the passage of RNA from the nucleus to the cytoplasm, and experiments of this sort have been quoted as evidence that all the RNA in the cell is synthesized in the nucleus[6,8]

However, these observations are open to more than one interpretation, and the kinetics of labelling of the nuclear and cytoplasmic ribonucleic acids can be explained equally well by assuming that the rapidly labelled nuclear RNA has a short life in the cell and that the cytoplasmic RNA is synthesized independently The work of Harris and Watts[9–13] indicates that much of the rapidly labelled nuclear RNA does undergo breakdown within the cell to acid-soluble compounds, and an increasing body of experiment[12–17] suggests that this breakdown occurs, for the most part, within the nucleus These experiments make it clear that redistribution of radioactivity between nuclear and cytoplasmic RNA does not necessarily represent transfer of RNA from nucleus to cytoplasm, but they do not demonstrate where the cytoplasmic RNA is synthesized

A more direct approach to the problem has been made by examining the ability of enucleated cells to synthesize RNA It has been shown that under certain conditions enucleate amoebae[18,19] and enucleate fragments of HeLa cells[20] do not incorporate radioactive nucleosides into RNA although they do incorporate radioactive aminoacids into protein These experiments do indeed suggest that the cytoplasm does not have the ability to synthesize RNA, but the objection has been raised that the process of enucleation is itself exceedingly traumatic and that the synthetic capacities of enucleate cytoplasmic fragments may not be a true measure of the synthetic capacities of the cytoplasm in the intact cell The force of this objection is enhanced by the experiments of Schweiger and Bremer[21] on *Acetabularia* These authors have shown that under the correct conditions of growth, but only under these conditions, a clear-cut net synthesis of RNA may occur in the cytoplasm of these cells after removal of the nucleus On the other hand, it may be argued that *Acetabularia* is a rather special case and that results obtained with it cannot be extrapolated to other organisms

Some recent experiments with tissue culture cells have shown that the antibiotic, actinomycin *D*, can, at certain concentrations, abolish all RNA synthesis in the cell except the terminal or sub-terminal incorporation of nucleotides into the soluble RNA[22–25] Since actinomycin *D* has been shown to form specific complexes with DNA[26] and to inhibit the DNA-primed synthesis of RNA *in vitro*[27,28], the fact that it can inhibit all RNA synthesis in the intact cell has been interpreted as evidence that all cellular RNA is made in the nucleus[22] However, it has now been found that in *L* cells there is some synthesis of both nuclear and cytoplasmic RNA which is resistant to very high concentrations of actinomycin D[17]. Moreover, when the synthesis of RNA in animal cells is stopped by actinomycin D the rapidly labelled RNA in the cell nucleus breaks down to acid-soluble compounds, but no transfer of RNA from the nucleus to the cytoplasm can be detected[13-17].

It is clear from the foregoing observations that the most convincing demonstration of cytoplasmic RNA synthesis would be one in which a substantial synthesis of RNA could be demonstrated in the cytoplasm of a typical animal or plant cell either after enucleation or under conditions in which synthesis of RNA on the chromosomes has been suspended. Such conditions are found in all animal and higher plant cells during the period of mitosis. It has been shown that incorporation of radioactive precursors into the nuclear RNA ceases completely by mid-prophase and does not resume until mid-telophase[29-31]. Prescott and Bender[30] and Feinendegen and Bond[31], using autoradiographic techniques, have examined the incorporation of radioactive precursors into RNA during mitosis by exposing cultures of HeLa and Chinese hamster cells to tritiated uridine and cytidine for periods of 5–30 min. These authors found that cells in metaphase and anaphase were not labelled and concluded that no synthesis of RNA occurs in the cell during these stages. However, under the conditions of labelling used by these authors there may be little or no incorporation of radioactivity into the cytoplasmic RNA of interphase cells in a 30 min period. It is therefore scarcely surprising that cells in metaphase and anaphase were not labelled. Indeed, under such conditions of labelling, it is doubtful whether these cells are a suitable material for the examination of the problem, since their mitotic time is probably not much more than 30 min.

In the present investigation the synthesis of RNA during the mitotic period has been re-examined with two important modifications in the experimental design: (1) cells with a longer mitotic time were chosen, (2) the conditions of labelling were such as to permit a rapid and virtually linear incorporation of precursor into cytoplasmic RNA in the cells in interphase.

It has been shown that, under standard conditions of culture, the meristematic cells in the root tips of the broad bean *Vicia faba* have a mean mitotic time of 3.9 ± 0.2 h (ref. 32). Four hours seemed long enough, since, even under the usual conditions of labelling, radioactive RNA precursors are incorporated into cytoplasmic RNA in interphase cells within this period. This material was therefore chosen for the experiments recorded here.

Since radioactive adenosine, cytidine and uridine can be incorporated terminally or sub-terminally into soluble RNA, the choice of guanosine as a precursor was indicated. No terminal incorporation of guanine nucleotides into soluble RNA has been reported[33]. A further indication that guanosine might be a suitable precursor arises from a consideration of the metabolic pathways by which adenylic and guanylic acids are synthesized[34]. It appears that the conversion of guanosine into adenine nucleotides is in general a much slower process than the conversion of adenosine into guanine nucleotides[35]. This would make it probable that, during a short period of incubation, radioactive guanosine would be incorporated mainly into RNA guanine residues.

The concentration of the radioactive precursor is also of importance. In most autoradiographic experiments tritiated precursors of very high specific activity are used and the actual concentration of the precursor in the medium is trivial. Under such conditions there is usually a lag before any appreciable radioactivity can be detected in the cytoplasm. The duration of this lag is variable, but in some cells it may be as long as an hour[36]. It has, however, recently been shown by Watts[37] that this lag may be greatly reduced, and in some cases virtually eliminated, if high concentrations of precursor are used. This effect is probably due to the repression of endogenous synthesis of purines and pyrimidines by high concentrations of related exogenous compounds[38].

Seedlings of *Vicia faba* were grown in aerated tap water until secondary roots were produced. The leaves were then removed and the roots of the plant were immersed at room temperature (approximately 20° C) in half-strength Knop's solution containing tritiated guanosine at a concentration of 5×10^{-4} M (Radiochemical Centre, Amersham, Bucks, specific activity 481 mc./mM). Samples of roots were removed at 30, 60 and 90 min, washed in water and fixed in acetic alcohol for 4 h. The fixed roots were hardened overnight in 4 per cent formalin, then washed in water and extracted for 30 min in 5 per cent trichloroacetic acid at 4° C. They were then washed in water, dehydrated through an alcohol series and embedded in paraffin wax. Sections were cut at 2μ. The mounted sections were extracted again with 5 per cent trichloroacetic acid at 4° C for 30 min and then washed in distilled water. Some of the sections were treated for 4 h at 37° C with ribonuclease at a concentration of 1 mg/ml. (Worthington Biochemical Corp., Freehold, New Jersey). Kodak 'V1042' stripping film was applied to the sections and the autoradiographs were developed after 80 days. The sections were stained, after the autoradiographs had been processed, with Ehrlich's hæmatoxylin and counter-stained with eosin.

Cells in full metaphase or anaphase were sought in the sections and the number of grains over each of 50 such cells was counted. Counts were made at the same time of the number of grains over the cytoplasm of two interphase cells adjacent to each cell in anaphase or metaphase.

The work of Gray and Scholes[39] on the duration of the stages of mitosis in the root cells of *Vicia faba* permits one to calculate that, in a total mitotic time of 4 h, prophase would last about 2.5 h and metaphase about 50 min. It is thus very unlikely that any of the cells in full metaphase or anaphase would have been in the first half of prophase 30 or 60 min previously, although a few might have been in this stage 90 min previously. Since synthesis of RNA on the chromosomes ceases by mid-prophase, any labelling of RNA in cells in full metaphase or anaphase must therefore represent labelling of cytoplasmic RNA, except, perhaps, in a few of the cells from roots exposed to the precursor for 90 min. In fact, none of the cells in metaphase or anaphase showed any evidence of chromosomal labelling even in the 90 min sample. This would be detected in an experiment of this sort by a greater concentration of grains over the chromosomes than elsewhere in the cell.

In order to determine whether all the acid-insoluble radioactivity was in nucleic acid, some roots were extracted with 5 per cent trichloroacetic acid at 90° C for 30 min and the amounts of radioactivity in the extract and residue determined. Some roots were subjected to overnight hydrolysis in 0.3 N potassium hydroxide, and the amount of radioactivity in the RNA purines was determined after these had been isolated and separated by paper chromatography[11].

Table 1 shows, for each period of exposure to the radioactive precursors, the mean number of grains over 50 cells in metaphase or anaphase and the mean number of grains over the cytoplasm of 50 pairs of adjacent cells in interphase.

Table 1. MEAN NUMBER OF GRAINS PER CELL

Period of incubation with labelled precursor (min)	30	60	90
Cytoplasm of cells in interphase	8.13 ± 0.6	17.28 ± 1.0	25.59 ± 1.0
Cells in metaphase and anaphase	16.08 ± 0.7	36.82 ± 0.9	65.24 ± 2.1

It will be seen: (1) The number of grains over the cytoplasm of the interphase cells increases in a linear fashion from zero time. This finding illustrates that the lag in cytoplasmic labelling can be eliminated if the right precursor is used under the right conditions. (2) The number of grains over cells in metaphase and anaphase increases progressively with time and is at all times at least twice as large as the number over the adjacent interphase cells This indicates that substantial incorporation of tritiated guanosine into acid-insoluble material occurs in the cytoplasm at a time when there is no synthesis of RNA on the chromosomes The large difference between the counts over cells in mitosis and adjacent cells in interphase may be due, at least in part, to the fact that for cells in mitosis the number of grains over the whole cell was scored, whereas for cells in interphase the area over the nucleus was excluded It is conceivable that, in sections, about half the radioactivity in the cytoplasm may be lost if the area overlying the nucleus is omitted from the count, although it is difficult to calculate the magnitude of this factor Another possibility is that in cells in interphase the rapid synthesis of RNA in the nucleus competes with the cytoplasm for the labelled precursor, whereas in cells in mitosis this competition is suspended In any event, it is clear that the amount of precursor incorporated in the cytoplasm of the cells in mitosis cannot be much less than the amount incorporated in the cytoplasm of the cells in interphase (3) While the increase in the number of grains over the cytoplasm of cells in interphase is linear for the whole of the 90-min period, the number of grains over cells in metaphase and anaphase is greater in the 90 min sample than the value obtained by a linear extrapolation through zero time and the 30 and 60 min samples The reason for this high value in the 90 min sample is obscure It could be explained by the fact that some of these cells might have been in the first half of prophase 90 min previously and might thus at metaphase contain some labelled chromosomal RNA If this were the case one would expect a proportion of the metaphase cells in the 90 min sample to show unusually high grain counts, and these would not be accompanied by correspondingly high values in the adjacent interphase cells But a statistical analysis of the grain counts revealed no evidence of this type of labelling Moreover, if the chromosomal RNA were labelled in some of the cells one would expect that the mean number of grains over cells in metaphase would be greater than over cells in anaphase But no significant difference was found between metaphase and anaphase in this respect

Treatment with ribonuclease almost completely removed the radioactivity from the cells in mitosis and from the cytoplasm of the cells in interphase This indicates that the cytoplasmic acid-insoluble material into which the precursor was incorporated was RNA All the acid-insoluble radioactivity in the roots was extracted by treatment with 5 per cent trichloroacetic acid at 90° C for 30 min Isolation of the RNA purines after alkali hydrolysis of the roots revealed that the radioactivity was almost entirely in guanine residues, the amount of radioactivity in RNA adenine residues was scarcely greater than background

Tritiated guanosine is incorporated into cytoplasmic RNA during those stages of mitosis in which synthesis of RNA on the chromosomes is suspended The amount of precursor incorporated into the cytoplasmic RNA of cells in mitosis is at least comparable with the amount incorporated in the same time into the cytoplasmic RNA of cells in interphase The tritiated guanosine is incorporated almost entirely into RNA guanine residues These findings do not support the view that all the RNA of the cell is synthesized on the chromosomes; they indicate that substantial synthesis of RNA takes place in the cytoplasm

STUDIES OF RADIATION-INDUCED CHANGES IN CELLULAR PROLIFERATION, USING A DOUBLE LABELLING AUTORADIOGRAPHIC TECHNIQUE

By Dr D. R. DAVIES* and Dr D E WIMBER†

Biology Department, Brookhaven National Laboratory, Upton, New York

RADIATION-INDUCED perturbations in proliferating cell populations can be due to the death or premature differentiation of a portion of the cell population, or to retardation of movement of certain phases of the mitotic cycle The last phenomenon is one that has long been recognized as one of the earliest consequences of radiation exposure Initially, the interruptions of the orderly progression of proliferating cells through the mitotic cycle were recognized through changes in the mitotic index[1], but critical analyses of the phenomenon became possible

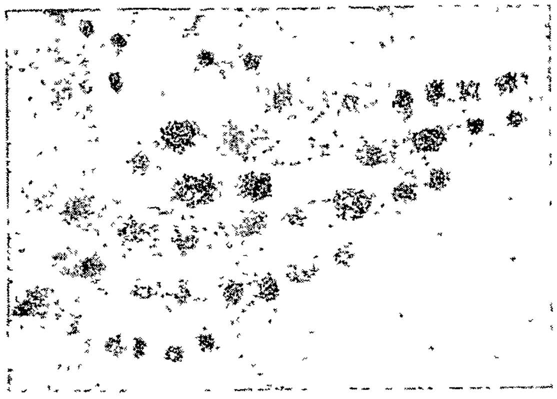

Fig 1 Autoradiographs of staminal hair cells tagged with tritium-labelled thymidine

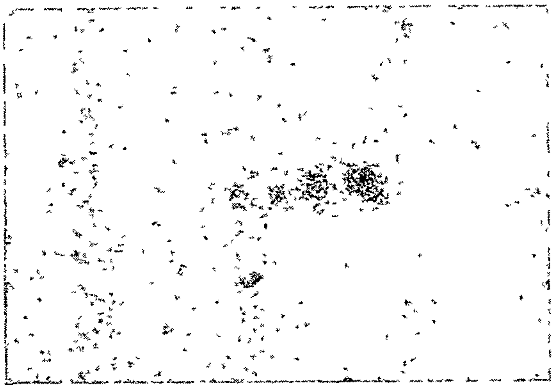

Fig 2 Autoradiographs of staminal hair cells that have been doubly labelled with ^{3}H- and ^{14}C-thymidine Cells with the silver grains directly over the nuclei are labelled only with tritium, those with a halo of grains around the nuclei are labelled with carbon-14

only after the advent of high-resolution autoradiographic techniques These have indicated that both the nature and extent of the changes induced are dose-, species- and probably tissue-dependent A few examples will suffice to indicate the diversity of responses observed G_2 (post-DNA-synthesis) blocks have been observed in HeLa[2], *Vicia*[3], *Pisum*[4], and mouse *S* (ref 5) cells, G_1 (pre-DNA-synthesis) blocks in *Tradescantia*[6–8], *Vicia*[9] and human cells[2,10] and blocks or delays in *S* (DNA synthesis) in mouse[11] and human[10] cells The doses used in the induction of these blocks have varied greatly if measured in terms of roentgens or rads, but until the nature and size of the relevant target or targets are known, comparisons of doses in these terms are not likely to be very meaningful[12]. The consequences of these delays or blocks, and the pattern of recovery with time, will probably also be varied and complex

In the experiments recorded here, an analysis was made (over an extended period of time) of the changes in the kinetics of an asynchronous cell population following a low dose of X-rays The double-labelling autoradiographic technique, and the particular tissues used, allowed a more critical evaluation of these changes than has previously been possible Moreover, from previous experience[13] it was known that the dose of X-rays used was sufficiently low that virtually no death or premature differentiation of the cells occurred, and the changes could be solely attributed to phase changes

The tissues used were staminal hairs produced within the flowers of a diploid clone (Sparrow's 02) of a variety of *Tradescantia occidentalis* Each flower has six filaments, each of which bears about 50 hairs (under the environmental conditions of the experiment—24 h light, 950 ft candles 21 ± 1° C) Each hair is a chain of single cells and its pattern of growth is as follows a cell in a filament divides in such a way that one of the daughter cells protrudes obliquely out of the filament This protruding cell is meristematic and becomes the terminal cell of the hair, continuing to divide until the mature hair (20–30 cells) is formed behind it The sub-terminal cell always divides once after its formation and occasionally an intermediate cell also divides Thus at any given time it is usually only the terminal and subterminal cells that are meristematic These terminal hair cells were superior to many tissues used in similar experiments because they were all known to be meristematic and because their unique position on the staminal hair eliminated complications introduced into most analyses by cell division In addition, cell lineages could to some extent be followed

The double-labelling autoradiographic technique utilized was similar to that described by Wimber and Quastler[8] The rationale of the technique is that a cell population is pulse labelled with tritiated thymidine and at a later time with thymidine labelled with carbon-14, or vice versa, and fixed immediately after administration of the second label Autoradiographs then reveal three groups of cells (*a*) those labelled with tritium alone, (*b*) those with carbon-14 (with or without tritium), (*c*) those with no label (Figs 1 and 2) If the tritium were given first, theoretically one would expect the number of terminal and subterminal cells labelled with tritium alone to increase as the interval between tritium and carbon-14 administration was increased (Fig 3) This increase would occur over the period of time it would take for the cells labelled with tritium (that is, those in *S* at the time of labelling) to move through G_2, *M* and G_1 If ^{14}C-thymidine were available at the time this block of cells commenced to synthesize DNA again, they would take up carbon-14 and so the number of tritium-labelled cells would decrease

Inflorescences were used which were still attached to the parent plant Each inflorescence contained a large number of buds The tips of buds with actively dividing hair cells were removed and the inflorescences immersed for 1 h in a water solution containing 1 μc /ml tritium-labelled thymidine (3 1 c /mM, New England Nuclear) One drop of 'Tween 80' per 20 c c solution was added to facilitate penetration of the thymidine into the bud As a further aid to penetration the whole plant with its inflorescences immersed in thymidine was placed in a vacuum for about 5 min at the beginning of the labelling period Preliminary experiments had shown that an adequate replacement of the air trapped within the buds, by thymidine solution, was difficult to achieve without this A low (1 μc /ml) concentration of tritium-labelled thymidine was used, as the work of Wimber and Quastler[8]

Fig 3 Diagrammatic representation of the ^{3}H-,^{14}C-thymidine double-labelling method used in these experiments Cells are visualized as passing through the nuclear cycle from left to right The cell populations are initially labelled with ^{3}H-thymidine and then at various later times are treated with ^{14}C-thymidine Fixation follows the second labelling

had indicated that the endogenous radiation from tritium could in itself affect the patterns of cellular proliferation. At the end of the labelling period the buds were thoroughly washed in water, the control series returned to the growth chamber and the irradiated series exposed in air to 54 r. of X-rays (6 m.amp, 250 kV, 1 mm aluminium filter, dose rate 108 r./min) prior to its also being replaced in the growth chamber. The inflorescences were wrapped in polyethylene 'gloves' after treatment to prevent undue drying of the buds following excision of their tips. At various intervals of time of 2–37 h after exposure to the tritium-labelled thymidine, the buds were immersed in a water solution of 2 μc./ml. ^{14}C-2-thymidine (25 mc./mM, New England Nuclear) for 1 h, under the same conditions as for the tritium-labelled thymidine exposure. Immediately after the treatment with carbon-14 the buds were washed and fixed in 3 parts absolute alcohol: 1 part glacial acetic acid. Later they were hydrolysed in 1 N hydrochloric acid for 6 min at 60° C, stained by the Feulgen method, the filaments dissected out, and squash preparations made of the filaments and hairs. Autoradiographs were prepared using two dips of Kodak *NTB* liquid emulsion, the slides were exposed for 3·5 months and were developed using standard procedures. After developing, the slides were counterstained in 1 per cent fast green to aid in the recognition of the terminal cells of the hairs. These terminal and subterminal cells were then scored for the presence and type of label and division stage. A differentiation of tritium-labelled cells into those which were in G_2, that is, those which had not divided, and those in G_1, that is, those which had divided, was also possible at the earlier fixation times (Fig. 4). Initially it was only the two meristematic end cells that took up label—after division the cells which were not going to divide again remained in G_1 for a considerable time. Ultimately these cells synthesized more DNA—this time without any further division, and accumulated up to 8C and possibly higher quantities of DNA (Davies, unpublished observations). Between 400 and 700 terminal cells were scored at each of the fixation times for control and irradiated series, and data on a similar number of subterminal cells also collected for the earlier fixation times. There was no significant difference between the pattern of behaviour of terminal and subterminal cells.

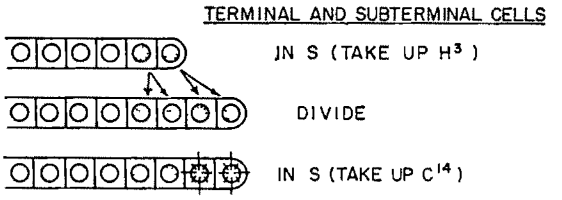

Fig. 4. Labelling patterns observed in the meristematic cells of the staminal hairs. Only the first two cells are meristematic at any one time. By observing the labelling distribution it is possible to determine whether cells are in G_2 or G_1 after double labelling. Those having two tritium-labelled cells distally are in G_2, while those having four tritium-labelled cells distally are in G_1

Control series. The percentage of cells in S, that is, those labelled with carbon-14, remained fairly constant throughout the cycle (Fig. 5)—the mean value for all fixation times being 52·0 per cent. There may have been a slight reduction in the number in the period 2–10 h after administration of the tritium label, probably due to a reduced flow of cells from G_1 to S (Fig. 5). A similar effect of the endogenous radiation from an incorporated radioactive label has been observed by Wimber and Quastler[8]. The rate of movement of cells in the mitotic cycle was given by the slope of the line denoting the increase in tritium-labelled cells, 2–8 h after labelling. This increase was due to cells leaving S and moving into G_2, M and G_1, the time at which they started decreasing again therefore represented the sum of G_2, M and G_1.

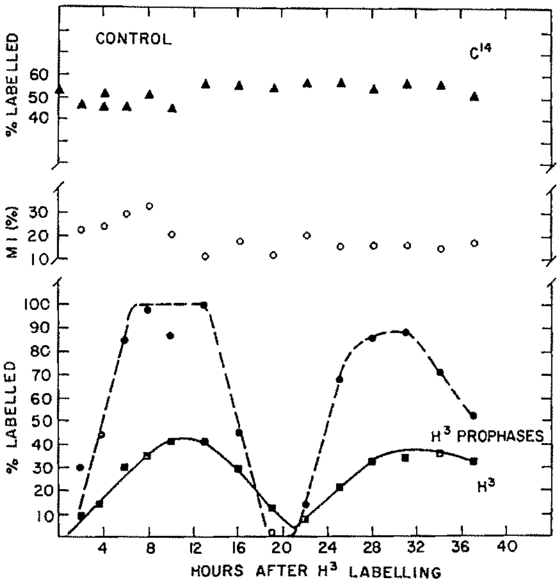

Fig. 5. Control series. Data collected from apical cells only. Top, carbon-14 labelling indices; middle, mitotic indices; bottom, labelled prophase curves and tritium-labelling indices. See text for interpretations

In other words, those cells which were in S at the time of tritium labelling were starting to enter S again—this time they would take up carbon-14, and the tritium label would not be recognized. The slope of the increase in number of tritium cells from 2–8 h was 4·77 per cent/h (Fig. 7). Since the mean number of cells in S was 52·0 per cent, the total time of S must have been approximately 10·9 h minus 1 h labelling time—9·9 h (1*a*)

S could also be estimated, but not as accurately as in (1*a*), from the distance between the 50 per cent points on the upward and downward slopes of the labelled prophase curve—12 h minus 1 h labelling time—11 h (1*b*)

The total cycle time (T) could similarly be calculated from the rate of movement of cells and was 21·0 h (2*a*)

Another estimate of T, from the distance between the two 50 per cent labelled prophases points on the upward slopes of the successive cycles, was 20 h (2*b*)

Yet another was 20·5 h—the distance between the 20 per cent tritium-labelled cells on the upward slope for the two cycles (2*c*)

The mitotic index, being based on many fewer cells, was somewhat variable but had a mean value of 19·3 per cent, indicating a time of 4·0 h for mitosis (3)

The G_2+M+G_1 time could be obtained from the time taken to reach the peak of tritium labelling (Fig. 5), and was approximately 11 h. Similarly the difference between T and S from earlier estimates (1) and (2) was also approximately 11 h. The time of G_2+M was given by the distance between the lines representing the increase in tritium-labelled cells, and increase in divided tritium-labelled cells in Fig. 7. This interval G_2+M was 5 h, and knowing M to be 4 h (estimate 3) G_2 must have been 1 h (4)

The usual method of estimating G_2 is to determine the time between labelling and the 50 per cent labelled prophases point on the upward slope. One-half of the duration of the prophase and labelling time should be subtracted from this figure to give the value for G_2 approximately 3·5 h—not 1 h as calculated earlier. However, the slope of increase in number of labelled prophases was, in this experiment, very much shallower than the theoretically expected vertical line. This in part was due to the length of prophase (2 h), to the variation in the length of G_2 and to the length of the labelling period. Hence the best estimate of G_2 must be 1 h (4) and by difference $T-(M+S+G_2)$, an estimate of G_1 was $21·0-(4·0+9·9+1)=6·1$ h (5)

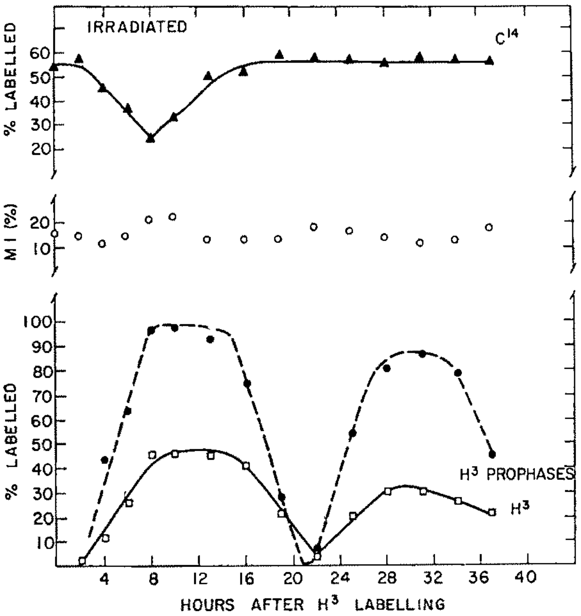

Fig. 6. Irradiated series. Data collected from apical cells only. Top, carbon-14 labelling indices; middle, mitotic indices; bottom, labelled prophase curves and tritium-labelling indices. See text for interpretations.

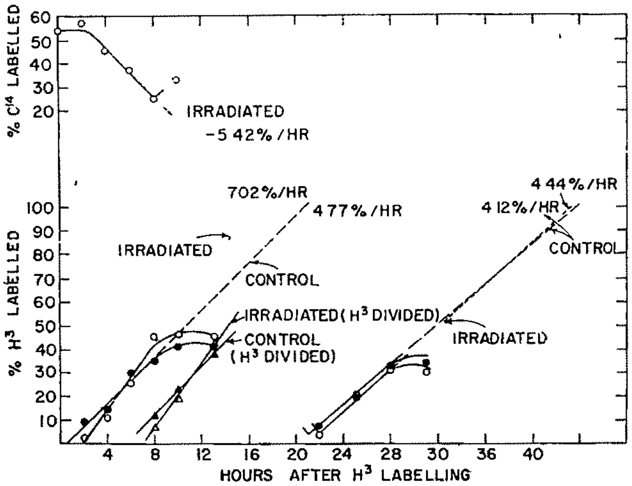

Fig. 7. Irradiated and control series compared. Top, decreasing carbon-14 labelling indices for the irradiated material, indicating a block in G_1; bottom, tritium-labelling indices for both control and irradiated material with slopes plotted. In addition, the increase in divided tritium cells is plotted for both irradiated and control populations. These are determined by the method illustrated in Fig. 4.

Irradiated series. The time for the first post-irradiation mitotic cycle appeared little changed from that seen in the control (Figs. 5 and 6). However, within the cycles there were considerable differences. Emergence of cells from S was slightly delayed (compare the time of emergence of tritium-labelled cells after labelling in Figs. 5 and 6). However, after this initial delay, the cells moved through G_2, M and into G_1 at a faster than normal rate—7.0 per cent as opposed to the control value of 4.8 per cent/h (Fig. 7). The maximum proportion of cells labelled with tritium was similar in both the irradiated series and control, but the maximum level was maintained for a longer period of time. This indicated an increase in the time of G_2+M+G_1. Since the distance between the tritium-labelled line and the divided tritium-labelled line, that is, G_2+M, was similar for control and irradiated (Fig. 7), it must have meant a radiation-induced increase in G_1. That this was the case was shown conclusively by the carbon-14 labelling index, that is, the number of cells in S at any given time. Up to 2 h after tritium labelling and irradiation there was no change, but this may well have been due to a block both in cells leaving S, as considered earlier, and in the entry of cells into S from G_1. However, after 2 h the carbon-14 index dropped to a low value of 23 per cent at 8 h (Fig. 6). This decrease could be interpreted as being due to an almost complete blockage of cells in G_1—the theoretical line predicted for a complete block would drop to 14 per cent at 8 h, if the rate of cells leaving S were 7.0 per cent/h. Movement of cells from S to G_2, M, and G_1 (that is, increase in tritium-labelled cells in Fig. 6), it must be remembered, was not retarded. From 8 h onwards the number of cells taking up carbon-14 increased rapidly. If the flow into and out of S had been restored to its normal value, S would have remained at its low level (23 per cent). The rapid increase in the number of labelled cells back to the normal value indicated a more rapid than normal flow from 'G_1' into S. The definition of S in the particular context of this experiment now becomes ambiguous. It is conveniently equated to that stage in which precursors are incorporated into DNA. However, the cells which were prevented from incorporating thymidine (2–8 h post-irradiation) were possibly 'competent' in every respect other than their DNA content, and, once the block to thymidine incorporation was removed, surged through 'S' at a faster than normal rate. The radiation-induced lesion—the possible nature of which has been summarized by Stocken[14]—was temporary in nature and its influence transient, having no effect on the subsequent mitotic cycle. In the second cycle, rates of movement of cells, the number of cells in S, etc., all appeared similar to that seen in the control (Figs. 5, 6, 7).

The experimental material utilized here appeared similar, in its type of initial response, to *Tradescantia* roots[7,8], but not in its pattern of recovery. Even with the low doses of radiation used on the root systems (1 and 10 rads), there was no marked recovery within 20-h post-irradiation. The extent of the 'G_1 effect'—leading to a 40–50 per cent depression in the number of cells in 'S'—was similar for both, and similar to that observed in human bone marrow cells[10]. In the case of the latter tissue it was suggested that either the G_1 population was heterogeneous in terms of radiosensitivity, or that its rate of movement was halved. In contrast to these results, the present experiments showed that most of the G_1 to S cells were for a period of time impaired with respect to their ability to take up tritium-labelled thymidine. They then recovered at a rapid rate. If there had been a blockage and an accumulation of a large number of cells in a normal G_1 state, then a partial synchronization of cells would have resulted, and changes in the mitotic index observed. There was no direct correlation between the effects on DNA synthesis and on the actual process of cell division (the mitotic index was essentially unchanged throughout) and in contrast to most experiments the blockage in G_1 was induced at a lower dose than the latter. Furthermore, the long-term consequences of this effect on DNA synthesis must be negligible, at least in terms of survival of the cell, since 54 r. has little effect on this parameter[13].

TREATMENT OF CANINE NEOPLASMS WITH AUTOGENOUS VACCINIAL PREPARATIONS

By Dr. C. W. RIGGS
University of California Medical Center, Vivarium, San Francisco

IN a previous report[1] a procedure was described wherein it was demonstrated that an immune response was invoked in *A* strain mice against sarcoma 37 when the mice received implants of their own sarcoma 37 which had been grown in a strain of mice normally resistant to this tumour. Twenty of one hundred experimental mice were afforded complete protection from a single implant of the altered tumour. The average life-span of the eighty which eventually died of sarcoma was twice that of control animals. In another similar experiment (not reported) involving the mouse mammary carcinoma *E*0771 in 100 mice, 25 per cent survived and the life span was again double the controls in those which developed tumours and died.

The procedure was based on the premise that a significant change might occur in a neoplasm if the neoplasm could survive and receive its nutrients in a genetically foreign host. Such a change could render the tumour antigenic when returned to the original host so that the host might reject the altered transplant. The antigens produced against the altered tumour might also be effective against the closely related original tumour. If the growth rate of spontaneous neoplasms is dependent on the host's ability to produce a limited amount of tumour antibodies, it is possible that the addition of even a weak antigen would tip the balance of tumour antibodies enough to bring about tumour regression.

An attempt was made to utilize the same technique on an aged female beagle hound which had a scirrhous mammary carcinoma with nineteen palpable breast lesions ranging from pea size to two lesions approximately 1,000 c.c. in volume. There was radiological evidence of lung metastases and the bitch evidenced severe dyspnœa, anorexia, loss of weight, and lethargy. The abdominal skin was darkly pigmented in large patches.

The largest lesion on the beagle was removed surgically, a fragment was minced and one piece implanted subcutaneously into each of ten 3-week-old Swiss strain mice. The mice were each injected with 1 mg of prednisolone daily, and at the end of one week palpable tumours were growing in five of the ten mice. A section of the mouse-grown tumour is illustrated in Fig. 2. A biopsy of the beagle's second large lesion was taken for histological study and comparison of the tumour before (Fig. 1) and after treatment (Fig. 3).

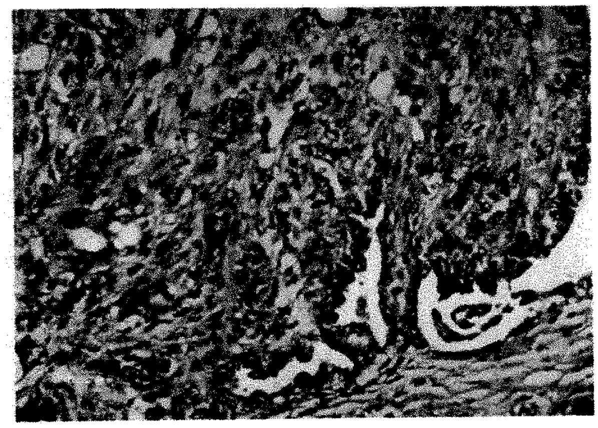

Fig. 1. Scirrhous mammary carcinoma of beagle, before treatment

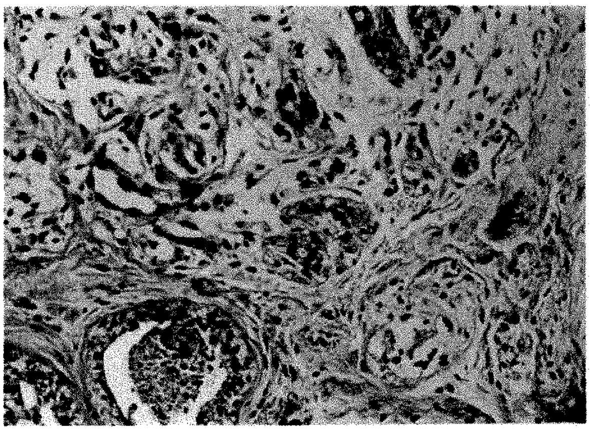

Fig. 2. Beagle tumour after growing in mouse 7 days

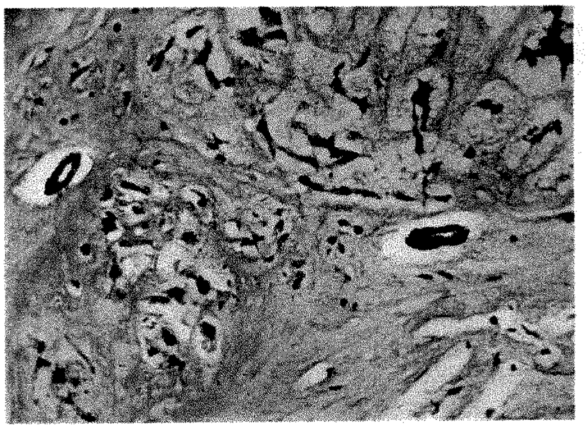

Fig. 3. Section of tumour shown in Fig. 1, 45 days after treatment

One mouse bearing the canine tumour was killed on each of the seventh, eighth, ninth and tenth days after implant, and the tumour tissue from each was returned to the beagle within 1 min after collecting. Implants were made subcutaneously by means of a 19*ga* trocar and cannula in the dorsal cervical region on the four successive days. Induration occurred at each implant site and persisted for approximately four days, but no growth of the mouse tumours occurred after their return to the beagle. The beagle received no other form of therapy.

Two of the eighteen breast tumours were measured on the day of the first mouse-grown implant. One, almost cuboid in shape, had a volume of 930 c.c., and the second, a shallow lesion, had an area of 7·5 cm². Measurements one week later were 600 c.c. and 3·75 cm², respectively. The tumour dimensions continued to decrease slowly, and three months after treatment the largest lesion volume was 345 c.c., while the smaller had completely disappeared. Eight other small lesions were no longer evident. The bitch weighed 6·2 kg before treatment and 9 kg three months later. Dyspnœa and anorexia subsided and normal vigour was restored. Pigmentation of the skin was no longer evident. The gross appearance of the largest lesion changed throughout the course of observation from a soft lumpy mass to a hard nodular mass. Biopsy sections taken 45 days after treatment with the mouse-grown tumours showed marked fibrosis, no mitotic figures, crenated and pyknotic nuclei. The animal lived 1·5 years after treatment with no apparent recurrence of her carcinoma, and died of causes incident to old age.

Another case treated in a similar manner, as an 'out-patient', deserves mention although it was not followed long enough to draw any definite conclusion. This was a ten-year-old male Afghan hound with generalized lymphoblastic sarcoma involving gross enlargement of all palpable lymph nodes. The animal was treated in September 1959 with a single dose of nitrogen mustard. A slight regression of size of node was observed for a 2-week period, followed by rapid growth of nodes and development of diarrhœa, anorexia, vomiting and weakness.

A 1 mm cube of an enlarged cervical lymph node from the Afghan hound was implanted into each of ten prednisolone-treated mice. Rapid growth of the tumour occurred in seven of the ten mice. On the fifth, sixth and seventh days of growth in mice, the tumour was returned to the Afghan.

Seven days after the first treatment with mouse-grown tumour the dog was brought to the laboratory, by its owner, for examination. All palpable glands were half or less the size they had been at the onset of treatment. The appetite had improved, vomiting stopped, the animal was stronger, but the diarrhœa was more severe. No other therapy was given.

A week later the owner called to report the dog had appeared to improve, except for the diarrhœa, had been struck by a car three days prior to his call, died in its sleep that night, and had been buried. No post-treatment sections were available.

The regression of lesions in the case of the beagle hound, the Afghan hound, and the inhibition of growth of a sarcoma and a carcinoma in mice similarly treated, suggest the possibility of producing what might be termed an autogenous vaccinal preparation for treatment of neoplasms. Prolonged growth of a neoplasm in a foreign host would not be necessary for production of such a preparation. Any growth at all should be sufficient to produce some alteration of molecular structure such as transposition of elements in nucleic acids, substitution of some side-chains, etc. Such preparations might be highly host specific if the structure of ætiological agent of any given neoplasm is closely related to the genetic make-up of its host, so that an autogenous preparation, effective in one animal, would be ineffective in another with a similar-appearing tumour.

BIOMETRICS OF THE KARYOTYPE OF *PROTEMNODON BICOLOR*, WITH REFERENCE TO THE LIMITATIONS IN ACCURACY OF IDENTIFYING HUMAN CHROMOSOMES

By RUTH C. MOORE and Dr. G. GREGORY
Cancer Institute Board, Melbourne, Australia, and Department of Statistics, University of Melbourne

THE identification of human chromosomes depends mainly on the measured differences in their relative lengths and arm ratios at metaphase[1]. Both these parameters may vary in standard preparations owing to distortion or stretching caused by fixation and flattening of cells.

Identity can also be based on the appearance of characteristic constrictions and heteropyknotic regions. At the present time the significance of satellites on some human chromosomes is still *sub judice*[2-4]. The presence of constrictions on others has been noted[5,6] which, with further refinements of technique, may be sufficiently uniform to serve identification.

The magnitude of the variation in length and arm ratio is such that only the three largest human chromosomes and number 16 can be identified unequivocally; and this in turn means that it is impossible to assess variation and errors of measurement. However, the chromosomes of the Black-tailed Wallaby, *Protemnodon bicolor*, can be identified with ease. This species has a diploid number of 10 female, 11 male[7], the male having 2 Y chromosomes, perhaps due to centric fusion between the true X and a large acrocentric autosome which is the homologue of Y_2 in the male[8].

Two male wallabies were obtained with the co-operation of the Victorian Fisheries and Wild Life Department. The technique of Moorhead *et al.*[9] was used to examine chromosomes from peripheral blood.

A typical idiogram is shown in Fig. 1. Each of the four pairs of chromosomes is distinguishable. The X is similar in size to autosome 2, but can be identified by a constriction at the base of the short arm.

42 cells (21 from each specimen) were photographed on quarter-plate Kodak orthochromatic high-contrast film, and printed at a final magnification of 3,750. A piece of fine wire was laid along the midline of each photographed chromatid from the end to the estimated position of the centromere and the straightened wire measured against a ruler graduated

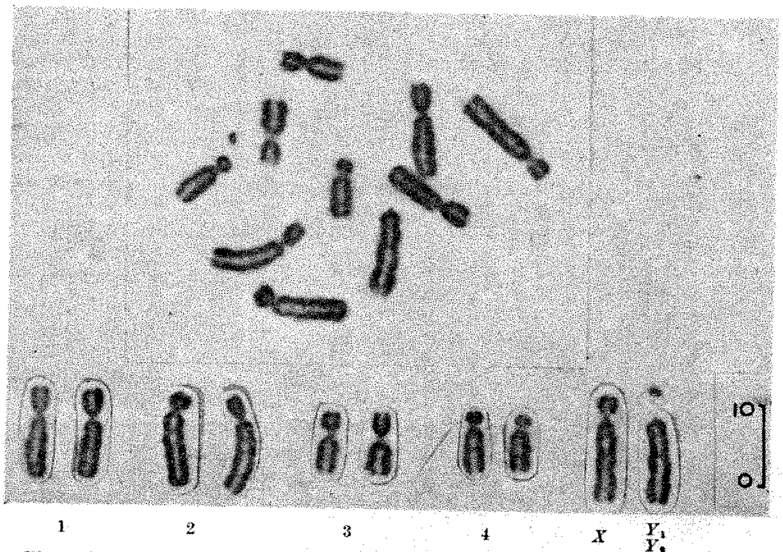

Fig. 1. Karyotype of a male black-tailed wallaby (*Protemnodon bicolor*) (scale in μ)

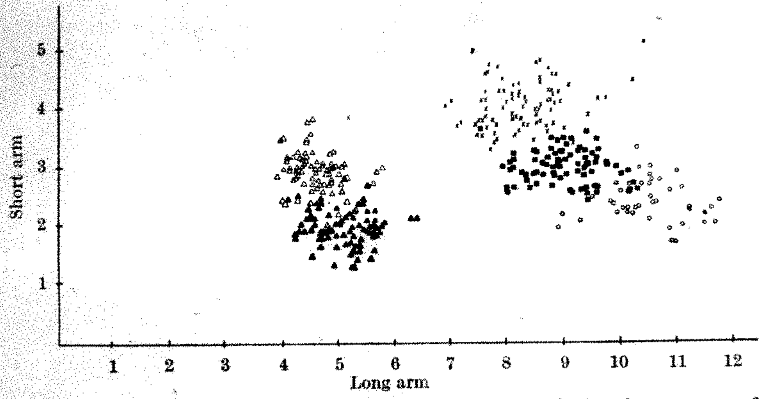

Fig. 2. Plot of short-arm versus long-arm measurements of the chromosomes of *Protemnodon bicolor*. Arm-length is expressed as a percentage of the total chromosome length in the cell. Crosses, chromosome 1; squares, chromosome 2; open triangles, chromosome 3; closed triangles, chromosome 4; circles, *X* chromosome

to 0·5 mm. Arm-length was taken as the sum of the chromatid lengths.

The Y_1 chromosome entering metaphase showed marked positive heteropyknosis and was, therefore, excluded.

The data were examined to find some criteria of identification the errors of which had a recognizable pattern. Initially, observed shorter versus longer arm-lengths were plotted, length being expressed as a percentage of total chromosome length per cell (Fig. 2).

The tendency for the results from each chromosome to cluster round some mean value is very noticeable. Identification with a high degree of confidence is still possible even in regions of overlap by considering the relative position of points corresponding to other chromosomes in the cell.

The larger chromosomes appear more variable than the smaller ones, and there is a tendency for the observations to be scattered in the shape of a sector of a circular annulus. That is, the two arm-lengths did not vary independently, but showed a weak negative correlation, presumably due to errors in determining the position of the centromere.

There appear to be two sources of variability-location of the centromere and total length of the chromosome. This suggests consideration of two parameters—the angle subtended at the origin by the plotted points (which, unlike the arm ratio, has the advantage of symmetry in the two arm measurements) and total chromosome length. These two variables were uncorrelated for each chromosome, indicating that the sources of variability are independent.

For any chromosome the following variables are defined: y = length of short arm as a percentage of total chromosome length in the cell; x = length of long arm as a percentage of total chromosome length in the cell; $\theta = \text{artan}\ y/x$, expressed in radians.

The data on the wallaby chromosomes are summarized in Table 1.

The wallabies are numbered in the order in which the measurements were made. The measurements on the second wallaby tend to be less variable, due, it is felt, to improvement in technique and greater discrimination in selection of material, and consequently rather more emphasis should be placed on the reliability of observations on the second wallaby.

The decrease in the variability of $x+y$ as the average value of $x+y$ decreases suggests a logarithmic transformation[10] to stabilize the variance.

If $z = \log\ (x+y)$, the standard deviations of z show greater stability and there is no relationship between mean and standard deviations.

The relationship between z, θ, x and y is shown in Fig. 3. The assumption is now made that the variability in the measurements on human chromosomes is governed by the same laws and can be analysed by the same procedures and hence that in a sample of sufficient size the variances of z and θ will be constant for all chromosomes.

Analysis of human chromosomes. 36 and 22 metaphase plates respectively from the peripheral blood of 2 male subjects were photographed under a Leitz 90 times objective and printed at a final magnification of 5,300. Measurements were made as before on pairs (1) and (2) and the largest and smallest pairs, arranged in order of length irrespective of arm ratio, of the 6–12 + X group (Denver classification).

Short-arm versus long-arm plots are shown in Fig. 4.

One immediate conclusion was that in the largest chromosome the shorter measurement does not always correspond to the same arm of the chromosome, hence the truncation of the region of variability along the 45° line, suggesting that the true value of the arm ratio is nearer 50 per cent than has previously been claimed. This has the effect of biasing the estimate of θ towards a lower value, although the variability of z is not affected.

Table 2 summarizes the data on human chromosomes. Chromosomes 1 and 2 exhibit stability in the means and standard deviations of their z values, and in the means of the θ values, but the standard error of θ for chromosome 1 is significantly lower due to the truncation mentioned

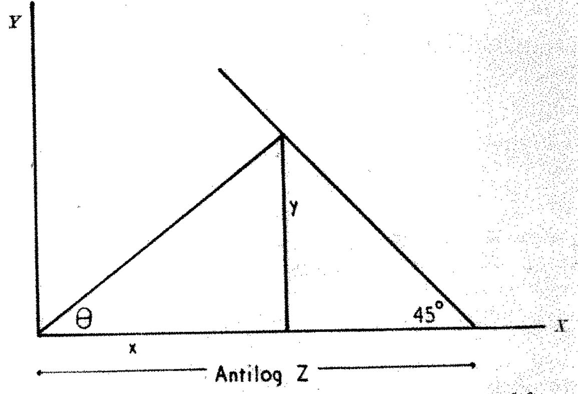

Fig. 3. Relationship between the parameters x, y, z and θ

here. The observations on the largest of the 6–12+X group indicate that the same chromosome has not been measured throughout. The criterion of selection was length, and the decreased standard deviation of z is consistent with the statistical theory of the extreme value of a sample[11]. The same conclusion can be drawn for the smallest pair in the group. In both cases, the increased standard derivation of θ indicates a mixed population. The two smallest chromosomes of the group have distinct arm ratios but similar lengths[12] (Fig. 5). The standard deviation of z in the smaller sample is approximately the same as for chromosome 2, but that of θ is larger.

Correlations between z and θ were not significant at the 5 per cent level for each subject and chromosome measured. This computation was not carried out for chromosome 1 owing to the unreliability of the estimate of θ.

In computing z values for Fig. 5, the lengths relative to the total lengths of the eight chromosomes measured have been taken. The more customary measure is the length relative to the total length of the 22 autosomes plus the X chromosome. The effect of the restricted measure is to add a constant to the mean, and to change the standard deviation. The size of this change depends on the relative size of the chromosome under consideration and the chromosomes measured. In the present case it can be calculated that the standard deviation of z for chromosome 2 relative to the complete haploid set is underestimated by approximately 6 per cent. Values of θ are unaffected by the scale of measurement of length. Correcting by the data published by Levan and Hsu gives relative lengths of 8·1 and 7·8 per cent for the first and second chromosomes respectively.

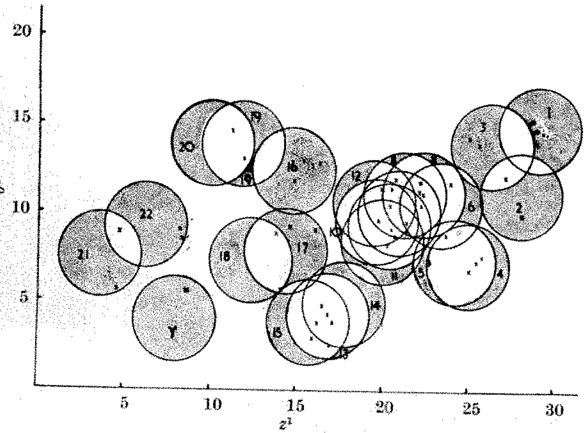

Fig. 5. Plot of z^1 versus θ^1 for the 22 human autosomes and the X and Y chromosomes, using the mean values of Levan and Hsu (ref. 12). The circles represent the boundaries of the 95 per cent tolerance regions. Shaded areas are those regions in which a value can be identified unequivocally. The crosses represent values of z^1 and θ^1 calculated from measurements of a single male metaphase cell

As chromosome 1 (and, to a certain extent, chromosome 3) will give a spuriously low standard deviation of θ, the standard deviation of chromosome 2 (0·50) is taken. The value of 0·032 for the standard deviation of z is found by taking the value from Table 2 for both subjects and correcting for using a limited sample. The magnitude of this standard deviation is a measure of the efficiency of one of us in taking the observations, and relates only to that individual. The smaller the value, the more accurate will be the identification procedure, but over-scrupulous selection of material to reduce errors in those chromosomes which can be identified is no assurance that the standard deviation of other groups will be similarly reduced.

The assumption of the normality of errors in z and θ permits the definition of tolerance regions for observed values about some assumed mean value for each chromosome. If the scales are corrected so that $z^1 = z/0{\cdot}32$ and $\theta^1 = \theta/0{\cdot}050$, z^1 and θ^1 are independent normal values with unit variance and the tolerance regions are circles centred at the mean value. For 95 per cent and 99 per cent confidence the circles will have radii of 2·45 and 3·03 respectively. These are the square roots of the corresponding percentage points of a chi-square distribution with 2 degrees of freedom.

Taking the mean values of Levan and Hsu, this gives the 95 per cent tolerance regions depicted in Fig. 5. In fact, as these authors have pointed out, individual means within a group are probably displaced outwards from their true value.

The difficulties of identification are depicted in Fig. 5. The shaded regions denote areas of the (z^1 θ^1) plane which are contained in one tolerance region only, and there would be cause to allocate a chromosome the point of which lay in such a region to the corresponding number. The remaining interior points would lie in the overlap of 2 or more regions and if possible could be allocated by default. But with present techniques there seems no possibility of allocating within particular groups.

An interesting feature of the diagram is that there are regions within the general regions of dispersion where points are unlikely to be found. An observation in one of these regions suggests an abnormal chromosome.

Examination of further cells from the same individual could confirm the deduction. If an abnormality had the effect of transforming the appearance from one group to another, this again would be discovered from the diagram.

It would obviously be advantageous if measurements could be reckoned on the basis of comparison with the autosome set only, as this would mean that male and female could be referred to a common plot As the X chromosome cannot be identified this is impossible, but the sexes can be compared if a correction factor is applied to measurements from one sex to reduce the estimated z values for chromosomes 1, 2 and 3 to a common value Similarly a correction value could be calculated for any abnormal idiogram with a gross change in total chromosome length, for comparison with normal chromosomes In the case of many abnormalities this correction would be small and could be ignored

It is suggested (1) That before any claim that an aberrant chromosome has been found is substantiated, the chromosome complement should be measured and the measurements specified, as the presentation of individual idiograms can be misleading owing to normal variations

(2) That the exercise undertaken by many authors of pairing off chromosomes within a group is unnecessary and can be misleading and that the recommendation by the Denver study group that the X chromosome be separated from the 6–12 group is inadvisable

(3) That the presence of any sporadic and unique chromosome aberrations (for example, after irradiation) can be confirmed only by a system of allocation like that described here Admittedly many aberrations will not be detected, but the practice of identifying them only by eye, although in fact depending on the same method, has no value, as different workers may vary considerably in acuity of visual perception and powers of self-persuasion

Note added in proof Since submitting this paper for publication, we have examined the chromosomes of some other marsupial species, and find that, for short chromosomes, both z and θ errors are increased In the human chromosomes 19–22 and the Y chromosome will have larger errors for z and θ than chromosomes $1\text{–}18+X$ This difference will be discussed in greater detail elsewhere[12]

We thank the Victorian Department of Fisheries and Wild Life, which provided the animals for this investigation, and Mrs J Uren, Misses B Lady, M Byrne and V Ferguson for assistance

EFFECT OF POSTERIOR PITUITARY EXTRACTS ON THE LIFE-SPAN OF OLD RATS

By Prof SYDNEY M FRIEDMAN and Prof CONSTANCE L. FRIEDMAN
Department of Anatomy, University of British Columbia, Canada

INVESTIGATIONS in the rat and in man have consistently shown a disturbance in salt and water metabolism with age Detailed analysis of electrolyte partition in muscle in the old rat has shown that there is a gain of sodium both in cells and in their fluid environment, a corresponding loss of potassium from cells, and a shift of water from cells to environment[1] This type of salt and water distribution is also characteristic of a preponderance of adrenal mineralo-cortical activity in relation to the concurrent level of neurohypophysial function[2] In this relation, adrenal cortical activity may be subnormal and still dominant if neurohypophysial function is ever lower The failure of an intracarotid injection of hypertonic sodium chloride to elicit an appropriate antidiuretic effect in the old rat indicates that a decline in neurohypophysial responsiveness[3] or effectiveness[4] does, in fact, obtain More recently, we have found that in such animals vasopressin tends to restore salt and water distribution towards normal, and, in association with this, improves their ability to perform work[5] The effectiveness of vasopressin is enhanced by the concurrent administration of a trace of aldosterone, suggesting that adrenal cortical function is also sub-normal in age

Since the metabolism of salt and water plays so critical a part in the body economy, an improvement in the old rat sufficient to affect work performance might well be expected to produce a demonstrable effect on life-span The experiments recorded here were designed to test this Because the experiments were necessarily long and our colony of aged rats limited, these first investigations were confined to two posterior pituitary extracts only Pitressin tannate in oil was selected as one test extract because of our previous experience of its effects and because of its sustained action Whole posterior pituitary powder (U S P , Armour) suspended in saline by sonic agitation (3 mg/ml) was selected as the second test extract to provide more complete neurohypophysial replacement This latter extract was freshly prepared each week, and its potency assessed in terms of its pressor activity in the rat

Male rats of an inbred Wistar strain 24 months old at the start of the experiment were used In this colony, rats of this age are clinically old and usually few survive more than another 6–8 months Two experiments were carried out In the first, 3 matched groups of 15 old rats were set out in individual cages One group remained untreated, a second received pitressin tannate and the third received posterior pituitary powder in suspension The treated rats were given 100 mU/100 g three times weekly in either case This dose corresponds to 50 mU/100 g/day which is the approximate replacement requirement for the rat with diabetes insipidus[2] In the second experiment, 2 matched groups of 16 were set out, the first to remain untreated and the second to receive 75 mU/100 g of pitressin tannate plus the same amount of posterior pituitary powder thrice weekly The experiments were terminated arbitrarily, the first after 7 months, the second after 6 months In both, a control group of 12 young rats, 4 months of age at the start, were maintained alongside the old groups Since nothing untoward occurred in these young groups and all survived the experiments in good condition they will not be considered further No special or individual care was given to any animal in these experiments

Although obviously not objective, the weekly technician's reports, especially during the first 3 months of treatment, directed attention to the healthier appearance of animals receiving the powder suspension The actual findings for the old animals are presented in Fig 1 Objectively, posterior pituitary powder decreased the mortality rate during an effective period of approximately 4 months By contrast, only one mortality rate operated for both the untreated and pitressin-tannate-treated groups, and there is even a small suggestion that the

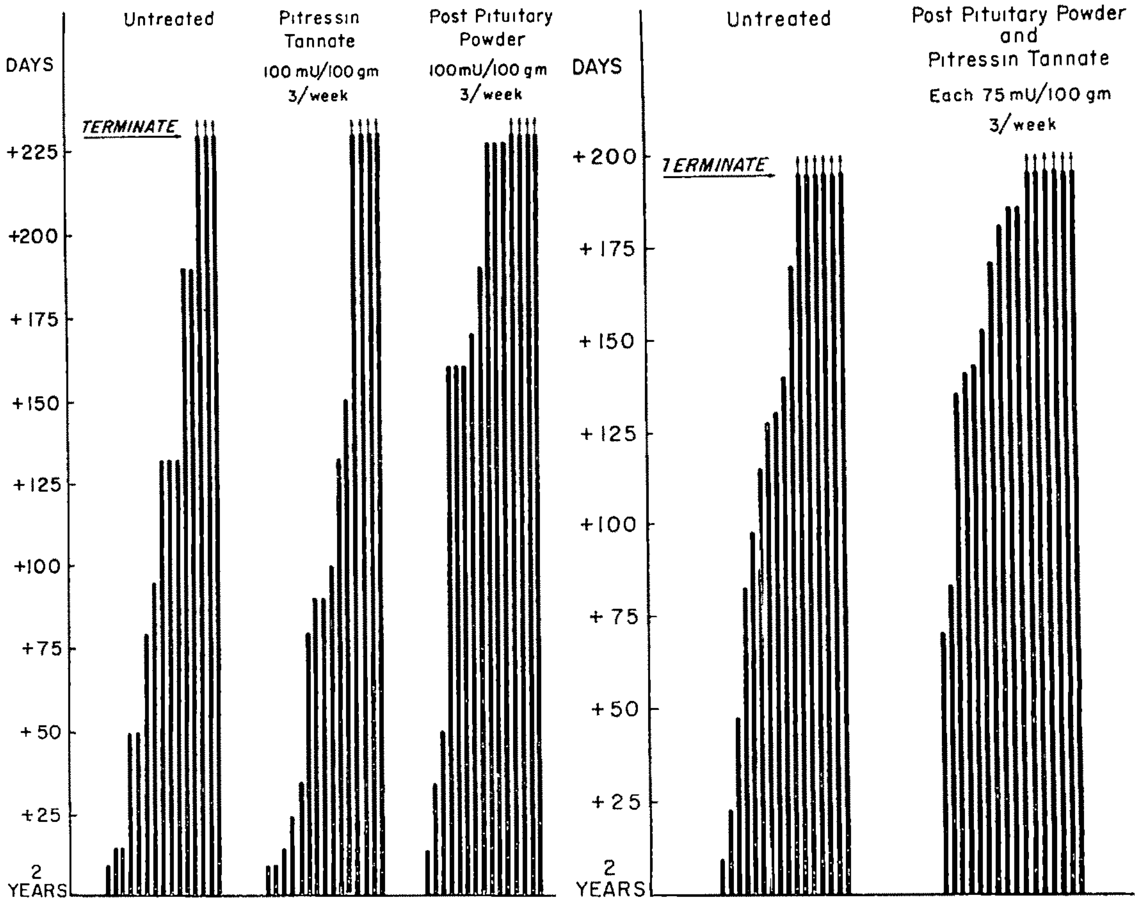

Fig. 1. Life-span in old rats treated with pitressin tannate and/or with posterior pituitary powder compared with untreated controls. Each animal is indicated by a bar and survivors at the time of termination by arrows. Experiments begin with 2-year-old animals

prolonged use of pitressin tannate may have been harmful. The beneficial effect was sharpest in the first experiment in which the larger dose of posterior pituitary powder and no pitressin tannate was used. Here the number of deaths in the untreated group 1 exceeded ($P < 0.012$) those in the treated group 3 by the 135th day of the experiment and this difference was maintained for almost one month. In the second experiment, a similar absolute significance, that is, survivors/deaths, was reached at the 130th day ($P < 0.026$) but was quickly lost. The concordance of the two experiments, of course, heightens the overall significance of the observations. Although a definite logic dictated the use of whole posterior pituitary powder, we must bear in mind that the results obtained with such a crude material might be due wholly to unrelated causes.

Since treatment with a suspension of whole posterior pituitary powder, imprecise as it was, temporarily reduced the death rate almost to zero over a span of approximately 3 months, more precise treatment should narrow the gap between average and longest individual life-span still further. The addition of a trace of aldosterone, for example, is indicated and an investigation of this has now begun. Certainly these, as well as previous beneficial results of therapy directed at the neurohypophysial–adrenal cortical integration, show that at least some of the phenomena associated with senescence can be delayed. The question of how long such a delay can be maintained remains open.

AGE RESISTANCE BY TURKEYS TO *EIMERIA MELEAGRIMITIS* TYZZER, 1929

By E. W. WARREN, S. J. BALL and JOAN R. FAGG
Veterinary Pesearch Station, May and Baker, Ltd., Ongar, Essex

ACQUIRED immunity to *Eimeria* spp. is dependent on previous infection in both chickens and turkeys. However, turkeys also show an innate immunity, age resistance, to infections of *Eimeria meleagrimitis*[1] and *E. adenoeides*[2,3]. This phenomenon is not shown by chickens[4-6]. So far, age resistance in turkeys has been demonstrated by showing that infections which are pathogenic to young poults are not pathogenic to older birds.

On inspection of recent results obtained in this laboratory in an attempt to obtain a clearer picture of this host–parasite relationship, the correlation between the

Table 1. Showing the Mean Number of Oocysts given and passed for Each Sub-group

Group*	Age at infection (days)	Sub-group	Mean weight (g)	Mean absolute No. of oocysts given	Mean No. of oocysts given/g body-weight	Mean No. of oocysts passed as millions per bird
A	8	1	79·2	7,920	100	152·87
		2	82·2	23,280	288	145·30
B	22	1	232·8	23,280	100	305·12
		2	238·8	60,280	255	192·78

* Uninfected control groups not included.

numbers of oocysts passed per oocyst given (reproductive index[7]) and age seemed to offer a useful criterion of resistance particularly when the number of oocysts given per gram body-weight was fairly constant.

To examine this hypothesis the following experiment was performed. At 14-day intervals day-old poults of either sex were obtained from a commercial hatchery and maintained free of extraneous infection as evinced by fæcal examination[8] twice a week, until 8 days (group *A*), 22 days (group *B*), 36 days (group *C*), 50 days (group *D*) and 64 days (group *E*). All the birds were then weighed and selected into groups by the method of Gardiner and Wehr[9], the main groups *A*–*D* having three sub-groups and main group *E* having two sub-groups. There were 4–5 poults in each sub-group.

All birds of sub-groups *A*1–*E*1, the experimental series, were given, orally, 100 sporulated oocysts of *E. meleagrimitis* (the same strain as used previously by Ball and Warren[10]) per gram body-weight according to the scheme shown in Table 1. Control sub-groups *A*2–*D*2 received the average number of oocysts given to the sub-group in the experimental series, which was 14 days older than itself. The oocyst dose of 100 per gram was selected in an attempt to minimize any 'crowding effects'[11,12]. The control groups, sub-groups *A*3–*D*3 and *E*2 were the uninfected controls.

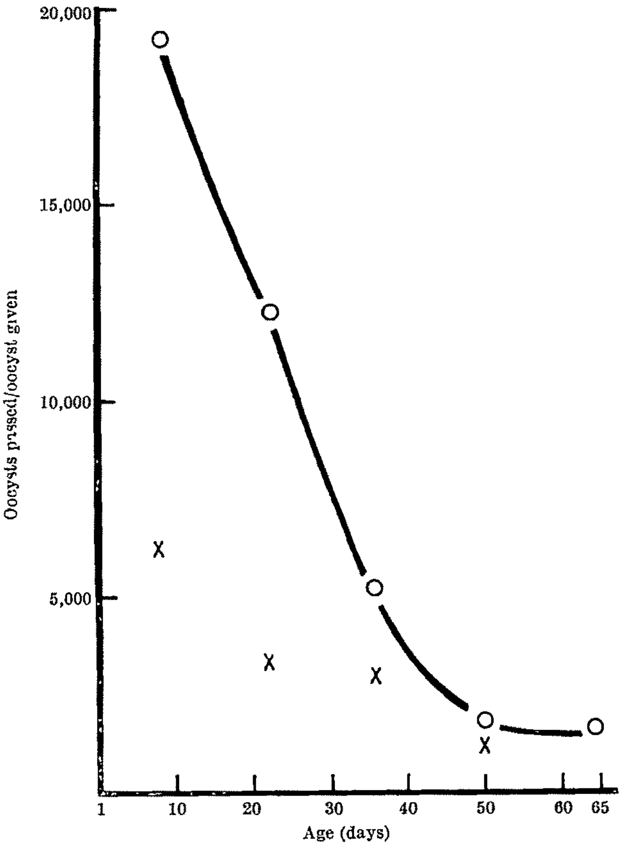

Fig. 1. Relationship between the numbers of oocysts passed per oocyst given and the age of turkey poults infected with *E. meleagrimitis*. O, Means for sub-groups 1; ×, means for sub-groups 2.

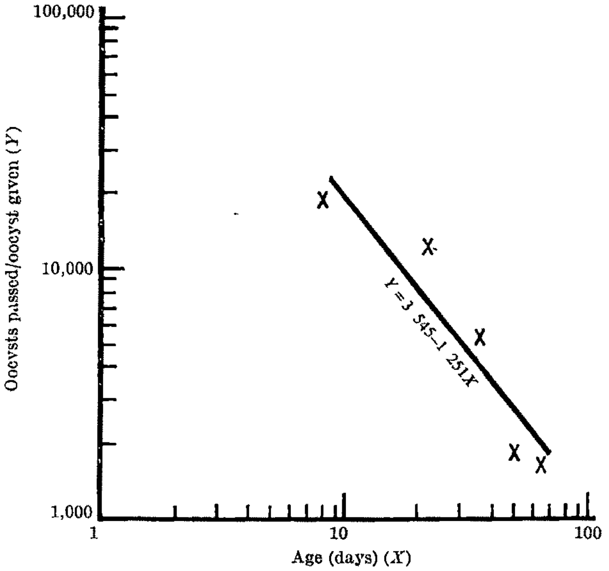

Fig. 2. The relationship (plotted on a log scale) between the numbers of oocysts passed per oocyst given and the age of turkey poults given 100 sporulated oocysts of *E. meleagrimitis*/g body-weight.

The poults were housed individually in wire-floored cages, in one of two rooms with continuous artificial lighting and heated according to their requirements. Unmedicated food and water were given *ad lib*. From four days after infection total oocyst counts[8] were determined at 24-h intervals for each individual poult until thirteen days after infection, when oocyst production ceased. No oocysts were seen in the fæces of any of the uninfected control groups throughout the test. The results are shown in Table 1 and are plotted in Fig. 1, as age against oocysts passed per oocyst given. Sub-groups 1 are comparable on the basis of a constant number of oocysts given per gram. Sub-groups *A*2 and *B*1, *B*2 and *C*1, *C*2 and *D*1, and *D*2 and *E*1 are comparable on the basis of total numbers of oocysts given.

Age resistance is shown in sub-groups 1 by the fact that the reproductive index decreases with age. If there were no age resistance, a horizontal line would be expected in Fig. 1, and this was obtained with a similar type of experiment using *E. acervulina* infections in chickens, for which age resistance has not been postulated.

The graph for sub-groups 1 (Fig. 1), showing the mean number of oocysts passed per oocyst given plotted against age in days suggests a curved relationship of the type

$$y = ax^{-b}$$

where y represents the mean number of oocysts passed per oocyst given and x represents age in days.

Transformed using logarithms (Fig. 2), this gives a straight line of

$$Y = 3{\cdot}545 - 1{\cdot}251X$$

the slope of which is significantly different from zero at $P < 0{\cdot}02$.

We conclude from this that given a constant number of oocysts per gram, the log number of oocysts passed per oocyst given is inversely related to log age.

No relationship could be found within the sub-groups for either the reproductive index or the total number of oocysts passed when plotted against weight.

Despite the older birds receiving fewer oocysts per gram than the younger birds, a similar relationship (Fig 1) was found to hold for sub-groups 2 as for sub-groups 1 If age resistance did not exist then it would be expected that the reproductive index for sub-group *A*2 would be the same as for sub-group *B*1 as they both received the same absolute number of oocysts, and similarly for sub-groups *B*2 and *C*1, *C*2 and *D*1, and *D*2 and *E*1 However, in each case except for sub-group *C*2, the sub-groups 1 are above their corresponding sub-groups 2 receiving the same number of oocysts If age resistance were the only factor affecting the results of these comparable groups, then the reproductive index for sub-group 1 would be less than that of their sub-group 2, but this is not so This could be due to a 'crowding effect'[11,12] within the gut This possibility is further supported by the fact that, although the falling off of the reproductive index with age of the sub-groups 2 is similar to that for sub-groups 1, it is less marked, which is probably due to the decreasing numbers of oocysts given per gram with age, so that the effects of 'crowding' become less in the older birds Presumably an arbitrary inoculum of 100 oocysts per gram is too many to avoid overcrowding using this experimental design and fewer oocysts per gram might avoid this

Inspection of previous results with *E adenoeides* suggests that the above relationship may also hold for this species, but a test designed to examine this has not been attempted

ROLE OF NON-COVALENT BONDS FOR THE HOLDING, ACTIVATION AND RELEASE OF MITOCHONDRIAL ENZYMES

By E EGGER and Prof. S RAPOPORT

Physiologisch-Chemisches Institut, Humbolt-Universitat, Berlin

WORK by us on latency, activation and release of mitochondrial enzymes has led us to a general conception of the relationship between their holding and activity The main points are as follows

(1) The enzymes are 'held' in the mitochondrion, that is, fixed by various bonds in the mitochondrial structure

(2) Release of an enzyme is brought about by the breaking of non-covalent bonds If such bonds mask the active centre of an enzyme, the phenomenon of latency is observed; activation is the breaking of the masking bonds

(3) Two types of mitochondrial enzymes may be distinguished (*a*) Non-sessile enzymes, held by weak bonds, which may be broken by freezing and thawing Thereby such enzymes are released and, if previously latent, activated (*b*) Sessile enzymes, which are held by additional types of bonds Activation of such enzymes is caused by breaking masking bonds of the first type

(4) Release and activation of enzymes are independent of mitochondrial swelling

Examples of activation and release of some mitochondrial enzymes are shown in Tables 1*a* and *b*

It would appear that all types of non-covalent bonds, which occur in the protein molecule, may also play a part in the holding and masking of mitochondrial proteins This is supported by our observations that the same conditions which affect the predominant breaking of such bonds also affect the mitochondrial enzymes

(*a*) *Role of imidazole bonding* The release of any $NADH_2$-cytochrome-*c*-oxydo-reductase from the mitochondria of rat liver and the conversion of the enzyme in a soluble diaphorase depend on the breaking of two imidazole bonds[1,2], which are responsible for the holding of the enzyme in the mitochondrion The breakage is caused by the ionization of the imidazole group This conclusion was based on *p*H-dependence and heat of reaction inactivation of the enzyme The *p*H-dependence of the activation of mitochondrial malic dehydrogenase follows an analogous course (Fig 1*A*) Liberation of mitochondrial proteins shows likewise similar *p*H-dependence[3] (Fig 1*B*)

The remarkable correspondence in the *p*H-dependence in all three types of processes would suggest that the imidazole bonds, which may be hydrogen bonds, are of general importance for holding and masking mitochondrial enzymes.

Table 1*a* ACTIVATION AND RELEASE OF ENZYMES BY FREEZING AND THAWING RAT LIVER MITOCHONDRIA

Enzyme	No of exp	Activity*		Final activity†	Activity in the final supernatant‡

§ Activity in 10^{-3} μmol SCN^-/min

Mitochondria were frozen at − 40° C Statistical significance of activation was proved by variance analysis, probabilities of error are given in the last column

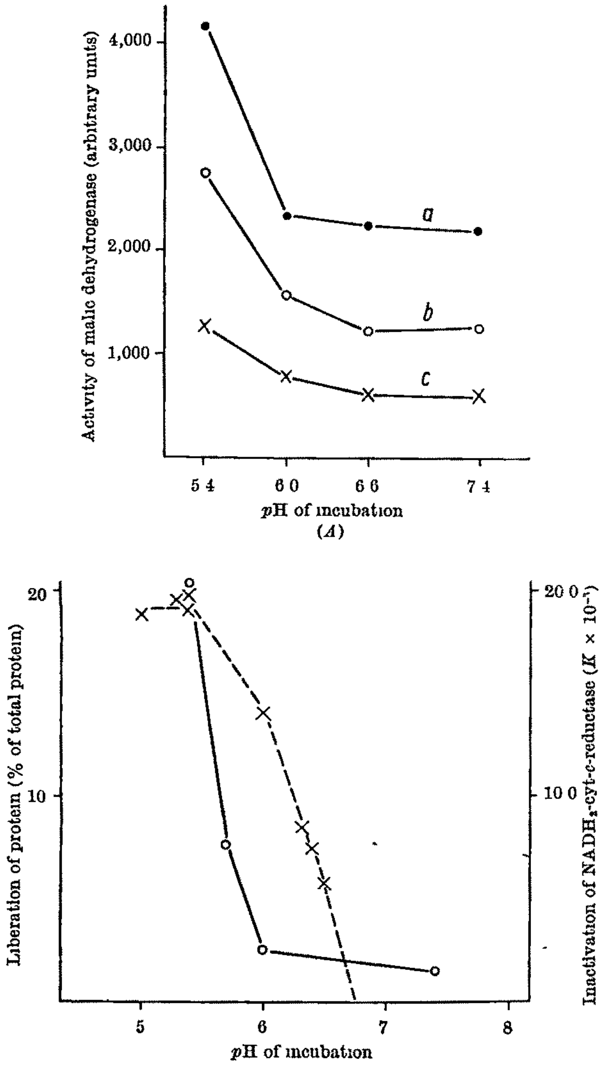

Fig 1 (A) pH-dependence of activation and liberation of mitochondrial malic dehydrogenase Incubation of mitochondria suspensions (a) 180 min at 25°, (b) 48 h at 0°, (c) activity in the supernatant of (b) (B) pH-dependence of liberation of mitochondrial proteins (ref 10) (full line, left scale) Mitochondria were incubated at 37° in 0 1 M phosphate buffer Values are the percentage of total mitochondrial proteins, released between 30 and 270 min of incubation For comparison rate of inactivation of the mitochondrial NADH$_2$-cytochrome c-oxydo-reductase at 0° is also shown (broken line right scale, the values are rate constants)

(b) *Peptide-hydrogen bonds* The importance of such bonds is suggested by the influence of urea In Fig 2a it is shown that activation and liberation of NADP-dependent isocitrate dehydrogenase of rat liver mitochondria by freezing and thawing may be enhanced by urea in low concentrations[4] In other work it has been shown that the latent NADP-dependent isocitric dehydrogenase of rabbit reticulocytes may be activated and liberated by incubation with urea[5] (Fig 2b) Liberation of mitochondrial proteins by freezing and thawing is likewise greatly increased by dilute urea solutions[4] (Fig 2c).

(c) *Electromagnetic interactions and hydrophobic bonds* The importance of these types of bonds is based on several observations Liberation of proteins, as well as activation and release of enzymes, is much greater in an ionic, as compared with a non-ionic, medium The effect of freezing and thawing depends on both the temperature and the duration of storage in the frozen state (Fig 3) Here also are differences between ionic and non-ionic media In sodium chloride the liberation of protein increases with lower temperatures, with sucrose the reverse is the case

It may be assumed that this effect is caused by the interaction of polar and hydrophobic bonds The stability of hydrophobic bonds, which are stabilized by entropy effects[7,8], decreases with lower temperatures, which may be the explanation for the effect of freezing and thawing

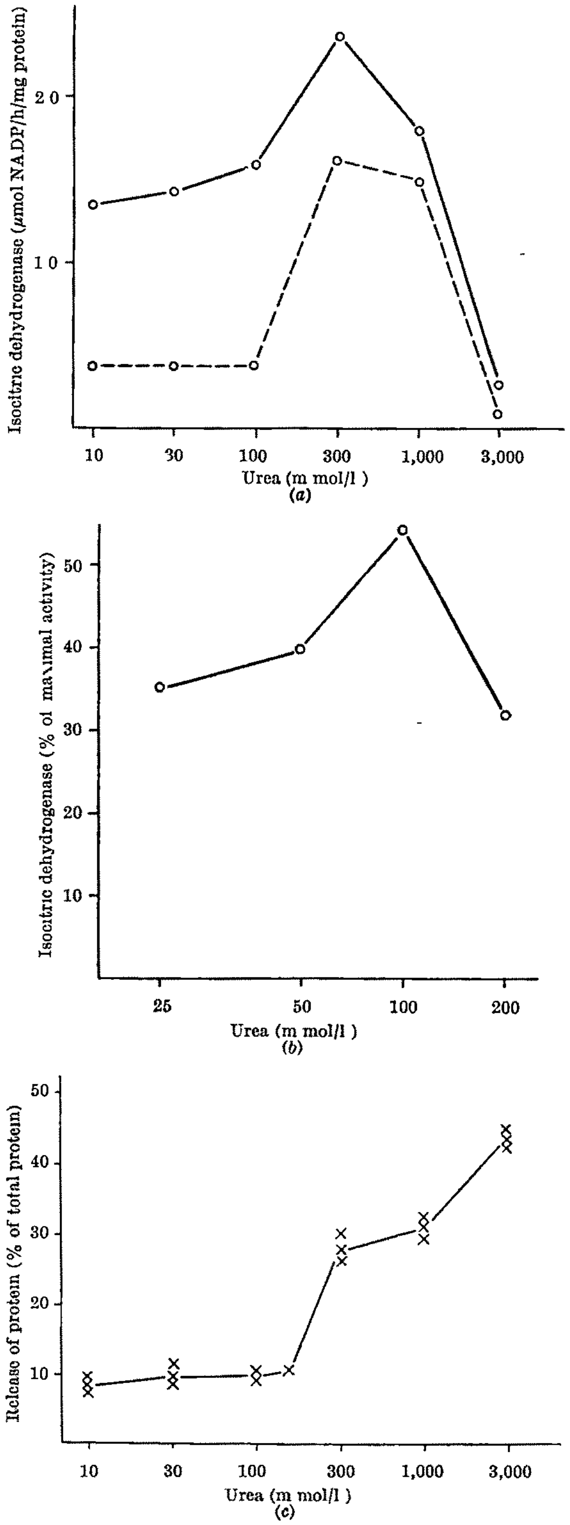

Fig 2 (a) Effect of urea on activation and liberation of NADP-dependent isocitric dehydrogenase from rat liver mitochondria by freezing and thawing at −36° Upper curve, activity of the suspension, lower curve, activity of the supernatant
(b) Effect of urea on the activation of NADP-dependent isocitric dehydrogenase in osmotic hæmolysates of rabbit reticulocytes by short-time incubation at 25°
(c) Effect of urea on the release of proteins from rat liver mitochondria by freezing and thawing at −36°

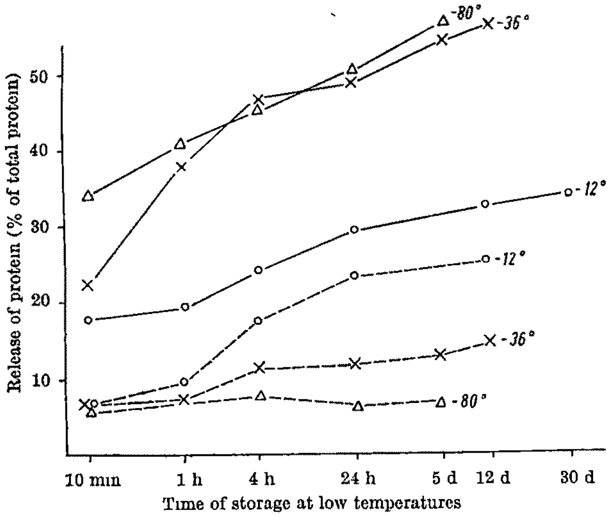

Fig 3 Effect of temperature and duration of storage in frozen state on the release of proteins from rat liver mitochondria in saline and in 0 25 M sucrose (ref 11)
——, 0 16 M sodium chloride, – – –, 0 25 M sucrose

The greater release in salt media is presumably caused by the breaking of both polar and hydrophobic bonds The fact that maximal liberation in salt media requires extremely low temperatures suggests a certain stabilization of the hydrophobic bonds by the ionic medium However, kinetic effects and modifications of the structure of ice may play a part An explanation on the basis of mechanical disruption of the mitochondrial membrane by ice crystals is difficult to imagine

Breakage of each type of bond may cause activation and release of a mitochondrial enzyme, greater liberation of proteins is observed when several effects are combined (for example, urea plus freezing and thawing, salt plus freezing and thawing) This speaks in favour of the co-operation of various bonds in masking and holding of the mitochondrial enzymes Such bonds may be of importance for the sessile, as well as the non-sessile, enzymes in the membrane as well as in the matrix of mitochondria

Mitochondrial swelling, although sometimes concurrent with activation or release of enzymes, may be shown to be an independent process (Fig 4) Usually it has a lower time constant[9]

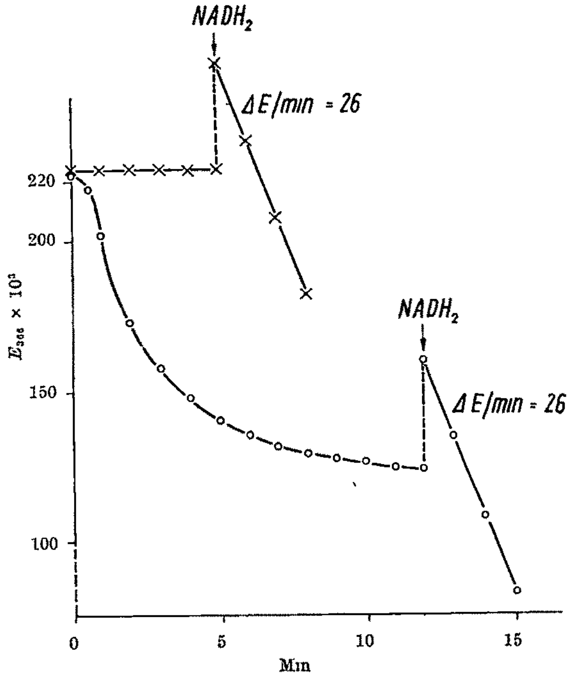

Fig 4 Activity of malic dehydrogenase in swollen and unswollen rat liver mitochondria Swelling is demonstrated by decrease of optical density before addition of NADH₂ Strong swelling results with phosphate, no swelling with salicylate (ref 12) Salicylate medium, sucrose 250, *tris* buffer *p*H 7 4 25, sodium salicylate 5, oxaloacetate 1, phosphate medium, sucrose 250, *tris* buffer *p*H 7 4 25, phosphate buffer *p*H 7 4 25, oxaloacetate 1 (m mol/l in the final test mixture)
×, Salicylate medium, O, phosphate medium

The question of permeability of the mitochondrial membrane will be considered elsewhere

FLUORESCENCE OF STYRENE HOMOPOLYMERS AND COPOLYMERS

By Dr S. S YANARI and Dr F A. BOVEY*

Central Research Department, Minnesota Mining and Manufacturing Co , St Paul, Minnesota

AND

Prof. R. LUMRY

Department of Chemistry, University of Minnesota, Minneapolis

THERE have been no fundamental investigations of the fluorescence of synthetic high polymers in solution, although polymer fluorescence has received some attention as a complicating factor in light-scattering measurements[1] The fluorescence of synthetic polymers, particularly polystyrene, in the solid state has been examined chiefly in connexion with their performance in scintillation devices, in which the polymer serves as solvent and energy donor[2] We have undertaken an investigation of the fluorescence of styrene homopolymers (both isotactic and 'atactic') and copolymers in dilute solution in the hope of obtaining new information concerning both the transfer of energy in large molecules and the conformations of synthetic polymers We have also carried out a very limited investigation of the fluorescence of films of these polymers The results of the first part of this work are reported here

In order to observe primarily those effects due to energy transfer within, rather than between, polymer molecules, we used dilute polymer solutions, ranging from 0 002 per cent for polystyrene (about 2 × 10^{-4} M in styrene units) to 0 015 per cent for the copolymer containing the lowest proportion (16 mole per cent) of styrene These dilute solutions also have the decided advantage of having

* Present address Bell Telephone Laboratories, Inc , Murray Hill, New Jersey

optical densities no higher than about 0.05 at the absorption maximum, thereby assuring that the exciting beam has a nearly uniform intensity within the sample cell. Commercially available fluorescence spectrometers are unsuitable for the measurement of dilute solutions of simple benzenoid compounds, and therefore, with the assistance of Mr Dale Burling (University of Minnesota), we have constructed a highly sensitive apparatus suitable for the examination of substances which absorb below 270 mμ and have very low fluorescence quantum yields. Briefly, it consists of a high-pressure xenon arc, the light from which enters an excitation monochromator after being chopped mechanically at 150 c/s. Monochromatic light is focused on a 1-cm square quartz sample cell held in a rotatable hollowed turret through which water is circulated to maintain a temperature of 20.0 ± 0.1°. The fluorescence is analysed at right angles to the exciting beam by an exit monochromator, the output of which is focused on a 1*P*28 photomultiplier. The signal from the photomultiplier is fed to a two-stage a.c. amplifier peaked for 150 c/s. Apparent excitation and fluorescence spectra are recorded by synchronized wave-length and recorded chart drives. Spectra were corrected for the combined effects of the wave-length response of the photomultiplier and attenuation of light by the analysing monochromator. Quantum yields were calculated from the areas of the corrected fluorescence spectra, tryptophan in aqueous solution being employed as a quantum standard[3].

The choice of suitable solvents is severely limited by the solubility of the polymers and by the necessity of being essentially non-absorbing and non-fluorescent from 250 to 350 mμ. *Cyclo*hexane (Eastman Kodak 'Spectro' grade) and 1,2-dichloroethane (Matheson 'Spectroquality') were found to be satisfactory. Most of our work was done in the latter.

Polystyrene, assumed to be 'atactic' or nearly so, was prepared in carbon tetrachloride, using stannic chloride as catalyst[4]. The molecular weight was low (*Mv* approximately 2 × 10^3) (ref. 4), facilitating solution in a variety of solvents. Isotactic polystyrene was obtained from Montecatini. The preparation of polymethyl methacrylate and the styrene methyl methacrylate copolymers has been described[5]. The polymethyl methacrylate showed only an extremely weak fluorescence, such as might be expected from aromatic end groups arising from the benzoyl peroxide initiator. It is probable that the fluorescence behaviour of our polymers was not significantly influenced by the terminal groups due to initiator. Although these groups might quench benzene fluorescence, they are present in very low concentration.

Typical fluorescence-emission spectra are shown in Fig. 1 which also contains the near-ultra-violet absorption spectra of solutions of 'atactic' polystyrene and isotactic polystyrene. Toluene, the two forms of pure polystyrene polymer and the copolymers were found to give substantially identical absorption spectra. The emission spectra of toluene and the 'atactic' polymer were identical within error. The most striking feature of the emission spectra is the appearance of a new band at 324 mμ in the isotactic polystyrene spectrum. This same band, but peaked at 320 mμ, is found in concentrated solutions of toluene or benzene and in the pure liquids, but not in *p*-xylene[6]. These substances show concentration-independent absorption spectra and the new band in toluene and benzene has been attributed to a dimeric species formed between an excited phenyl ring and one in the ground-state[7]. This species is called an excimer. It does not appear, however, that proof of the existence of this species has been given, at least for benzene and toluene. Since our polymers have identical absorption spectra, the new band might be due to excimer formation. For convenience, we shall henceforth call the dimeric or polymeric species responsible for the new band an excimer, realizing that this species may ultimately prove to be of a more complicated type.

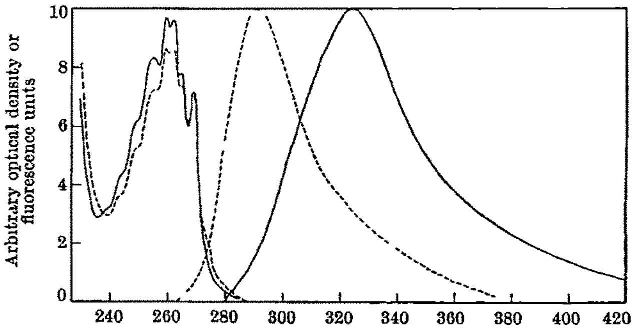

Fig. 1. Absorption and fluorescence spectra of 'atactic' and isotactic polystyrene in 1,2-dichloroethane. Solid line, isotactic; broken line, 'atactic'

The red band is developed in dilute solutions of isotactic polystyrene to about the same degree as in very concentrated solutions of benzene and it may be concluded that interaction between phenyl rings on the polymer is very efficient. It is reasonable to suppose that each phenyl ring can form an excimer with either of its nearest neighbours. If so, congruent plane-to-plane contacts between phenyl rings are not necessary for excimer formation, since such contacts are not possible in isotactic polystyrene.

In Table 1 the absolute quantum yields, Q_f, the wave-lengths of maximum fluorescence emission, λ_{max}, and the band-width of emission at half height are given for toluene, 'atactic' polystyrene and several copolymers of styrene and methyl methacrylate. The most notable features of these fluorescence characteristics are the increase in Q_f with decreasing proportion of styrene, the increase in λ_{max} with increasing styrene content and the increase in peak broadening with increasing styrene content. The behaviour of λ_{max} and of the peak width appears to be due to excimer formation here, too, since just these changes are observed in toluene solutions of increasing toluene concentration. However, the shift in λ_{max} is somewhat larger than might be expected on this basis and may be due in part to the increasing local polarizability as the styrene content is increased.

Since the 324 mμ band was never detectable in these solutions, the number of pairs of phenyl rings able, by reasons of geometry or time, to form excimers must be much smaller than in the case of isotactic polystyrene. It is not possible to decide, on the basis of our data, whether the small amount of excimer formation which does occur in these polymers is between adjacent phenyl rings on the polymer or between phenyl rings brought close together by close approach of two sections of polymer distant from each other along the polymer chain. Both situations would seem to be possible, but the high efficiency of excimer formation in isotactic polystyrene suggests that most excimers in the 'atactic' polystyrene and the copolymer are formed between adjacent phenyl rings. If so, quantitative measurement of the parameters of the emission spectra will provide an index of the number of 'isotactic pairs' of such groups. Of more utility, perhaps, would be the measurement of the 324 mμ band as a simple criterion to distinguish between isotactic and 'atactic' polystyrene.

The absolute values of Q_f, all but toluene, as given in Table 1, would appear to be reliable within ±10 per cent. The Q_f values for toluene solutions were erratic and will bear further study. Care was taken to deoxygenate solutions by repeated freezing. The decrease of Q_f in oxygen-free solutions can be seen to parallel the increase in λ_{max} and thus presumably the increase in excimer formation in the excited state. This suggests that the intrinsic lifetime of the excimer is significantly shorter than that of an isolated excited phenyl side-chain. However, Ivanova, Mokeeva and Sveshnikov[6] have reported

Table 1 FLUORESCENCE QUANTUM YIELDS (Q_f) OF POLYSTYRENE, STYRENE METHYL METHACRYLATE COPOLYMERS AND TOLUENE (0 002–0 015 PER CENT IN 1,2-DICHLOROETHANE, 20 0 ± 0 1°)

		λ_{max} mμ	Half-height width (mμ)	Q_f N_2	Q_f Air	Q_f O_2
Polystyrene, 'atactic'		292	30	4	3 5	3
Polystyrene, isotactic		324	47	1 5		0 7
Styrene methyl methacrylate copolymers

75 25	69	288	28	5	4	3
50 50	53	286	26	6	5 4	3
25 75	33	286	26	10	6	3 4
10 90	16	285	25	12	8 5	5 5
Toluene		281	26	8 ± 2		3

for benzene and toluene a longer lifetime and a larger fluorescence yield when excimer formation is increased by lowering the temperature In contrast to our results, benzene solutions have larger Q_f and presumably a longer fluorescence lifetime, the higher the benzene concentration It may be that the decrease in Q_f for the polymer is a consequence of the close association of phenyl rings, which might make resonance-transfer mechanisms possible In such a situation the migration of the quantum along the random chain of phenyl rings could lead to enhanced inter-system crossing to a non-radiative state, or, if traces of quenching agents still remained in these experiments, the efficiency of these substances could be enhanced by the rapid migration of quanta to a phenyl group already in contact with a quenching molecule[7]

It will be noted in Table 1 that the efficiency of oxygen as a quencher decreases as styrene content increases Hence, there is no net enhancement of fluorescence quenching as conditions are made more favourable to resonance energy transfer There is furthermore no evidence from absorption or emission spectra to indicate the presence of situations favourable to long-range migration of electronic quanta For example, there is no hypochromism in the spectra of 'atactic' or isotactic polystyrene From investigations of deoxyribonucleic acids[8,9] and helical polypeptides[10–14], hypochromism might be expected if the conditions for the occurrence of exciton behaviour were present in the polystyrenes We note also that Ivanova *et al* [6] have found self-quenching even in pure toluene or benzene to be very inefficient

Yet our experiments in systems with and without oxygen show that the Q_f of both excited monomeric side-chains and excimer formed from such side-chains decreases rapidly with increasing content of styrene Since these reductions in Q_f presumably imply a reduction in fluorescence lifetime and cannot be attributed to enhanced efficiency of quenching by external quenching agents, it seems necessary to suppose that linkage of the phenyl groups to the polymer introduces a new internal quenching mechanism or that the natural lifetimes of the excited states of monomeric and dimeric side-chains are reduced by their linkage to the polymer The reduction in lifetime is proportional to the styrene content of the polymers Hence, isolated phenyl groups are not strongly influenced, although some change in these units may occur

The predominant effect, however, appears to depend on the density of styrene units in the polymer The orientation of these units governs the amount of excimer formation but has only a secondary effect on the lifetime, since Table 1 shows that the fluorescence yield of isotactic polystyrene is reduced by only a factor of two when compared with Q_f of 'atactic' polystyrene If quenching by terminal groups is unimportant, as seems probable at this time, it might be supposed that there is an electronic coupling between the phenyl side-chains mediated by the polymer backbone which enhances quenching of the first excited singlet state of the phenyl groups However, we cannot suppose that the natural lifetime changes, since changes in Q_f would require a five-fold decrease in lifetime passing from toluene to atactic' polystyrene This change would require a very large decrease in area of the absorption spectrum, which is not observed Hence, it is necessary to postulate a quenching process in the polymer not involving in a significant way the energy or crossing probabilities for low-lying excited states, but rather a physical quenching dependent on the density of phenyl groups Apparently, the quenching process involves an approach of phenyl rings in such a way that excimer formation does not occur, or, if it does occur, has little bearing on the quenching reaction Such a process appears to be consistent with our several observations and particularly with the observation that the integrated area of the absorption band does not undergo any significant change with increasing styrene content The behaviour is inconsistent with the poor efficiency of self-quenching in liquid benzene or toluene and thus appears to be peculiar to the polymers

A preliminary investigation of the fluorescence of polymer films has also been carried out and provides information complementary to that supplied by solution spectra Films (about 2 cm² in area) were prepared by evaporating a 1,2-dichloroethane solution of the polymer on a 'Spectrosil' plate, which was then placed diagonally in the cell compartment in such a way that the fluorescence was analysed from a direction opposite to that of the reflected light Films of the copolymers containing the lowest proportions of styrene exhibited fluorescence spectra very similar to those of the solutions However, the fluorescence of the homopolymer film was very different from that of the solution, λ_{max} being shifted to much longer wavelength The thinner the film, the more striking was the effect Thus, a film prepared from a solution containing 0 25 mg of 'atactic' polymer per ml exhibited a λ_{max} at about 320 mμ, whereas a film prepared by evaporation of a solution containing 2 0 mg/ml had a λ_{max} at about 310 mμ The fluorescence spectra are evidently highly sensitive to differences of chain orientation occurring during evaporation

We are continuing work with styrene polymers and other polymers containing aromatic fluorophors We have also examined the fluorescence of a number of small molecule model compounds having aromatic rings strained and oriented in various ways Investigations of styrene polymers may provide useful information about the behaviour of excited states of benzene and related compounds Perhaps the most interesting result of this work is the difference in fluorescence properties of concentrated solutions of benzene and the polymers of high styrene content

CHARACTERISTIC BEHAVIOUR OF SOME CARBOXYLIC EXCHANGERS IN RELATION TO THE ABSORPTION AND DESORPTION OF POLYELECTROLYTES

By Dr C S KNIGHT, V C. WEAVER and B N BROOK

Whatman Research Laboratories, W and R Balston, Ltd , Springfield Mill, Maidstone, Kent

ALTHOUGH the usefulness of ion-exchange celluloses for the isolation, purification and separation of large ions is now established, the selection of a suitable derivative for a particular purpose is still based on a relatively small amount of fundamental information It is known that desirable properties are imparted to ion-exchange celluloses for use in the foregoing context by the physical and chemical characteristics of the cellulosic structure Thus, cellulose exhibits a very large surface area which is not dependent on macro-particle size In addition, the hydrophilic character of the cellulose molecule has the effect of enhancing accessibility of the ion-exchange sites in aqueous media Rapid rates of absorption and desorption, the latter under relatively mild conditions, are features of chromatography of large ions on selected ion-exchange cellulose derivatives

This article is an attempt to correlate the absorption and desorption characteristics of some new cellulose derivatives with the chemical and physical characteristics of the products It has been found convenient to compare the performance of cellulose derivatives with that of corresponding derivatives of 'Sephadex' (cross-linked dextran) and synthetic resin

Crystalline insulin was selected for use in this investigation because of its availability in pure form and its well-characterized properties

A standard solution was prepared by dissolving 1 0008 g of dry crystalline insulin in a mixture of 9 2 ml of 0 1 N hydrochloric acid and 100 ml of distilled water After solution the total volume was made up to 250 ml

Table 1 lists the derivatives used in this investigation together with their properties .

Table 1 CHARACTERISTICS OF SOME CARBOXYLIC EXCHANGERS

Exchanger	Ion-exchange capacity m equiv /dry g	Water regain	Physical form	Ionic form
'*CMC* (*a*)'	0 25	1 50 H 1 60 Na	Powder	Sodium
'*CMC* (*b*)'	1 0	1 78 H 2 57 Na	Powder	Sodium
'*CMC* (*c*)'	4 5	1 71 H 3 35 Na	Powder	Sodium
'*CM* Seph *C* 25'	4 4	4 85 Na	Powder	Sodium
'*CM* Seph *C* 50'	4 4	6 04 H 19 85 Na	Powder	Sodium
'Zeo Karb 226'	10	0 8–1 0 H	Beads	Hydrogen

The exchangers were cycled through their sodium and hydrogen forms on a Buchner funnel using 0 5 N sodium hydroxide and 0 5 N hydrochloric acid and retained in their hydrogen form Excess acid was removed by washing with de-ionized water until the filtrate was of neutral *p*H In the case of the cellulose and 'Sephadex' exchangers the samples were shaken with de-ionized water for a further 24 h, filtered, and finally washed to neutral *p*H All the exchangers were retained for use in a swollen state

A calculated excess of standard insulin solution, the same for each sample, was rapidly added to a sample of exchanger (about 0 5 g) with continuous stirring Filtered samples (1 ml) of the ambient solution were taken at timed intervals Each sample was diluted with 5 ml de-ionized water and its ultra-violet absorption at 276 5 $m\mu$ measured

The exchanger, saturated with insulin, was filtered off and washed with de-ionized water until free of excess insulin A calculated excess of 0 01 N hydrochloric acid was added rapidly to the exchanger with continuous stirring Filtered (1 ml) samples of the ambient solution were taken at timed intervals, diluted with de-ionized water (5 ml) and their ultra-violet absorption measured at 276 5 $m\mu$

Any insulin still remaining bound to the exchanger was removed by washing with 0 1 N sodium hydroxide Excess alkali was washed from the exchanger which was then reconverted to the hydrogen form, washed, dried and weighed

A summary of the results obtained on the carboxylic exchangers is recorded in Table 2 The significance of the measurements recorded in this table is as follows

The fraction of the theoretical capacity used up by the absorbed insulin is dependent on the relative affinity of the exchanger for, and the accessibility of the exchanger to, the insulin ion whereas the fraction of the absorbed insulin which is afterwards released is dependent only on the relative affinity of the exchanger for the insulin

The time taken to complete 50 per cent of the absorption provides a convenient means of comparing the relative speeds of the absorption process on the different exchangers and provides an indication of the part played by the accessibility factor in determining the fraction of the theoretical capacity used up during absorption

Table 2 ABSORPTION OF INSULIN ON AND DESORPTION OF INSULIN FROM CARBOXYLIC EXCHANGERS

Derivative	Nominal capacity m equiv / dry g	Water regain	Insulin Absorption				Insulin Desorption			
			Insulin absorbed m equiv / dry g	Fraction of theoretical capacity used (%)	Time taken to complete 50% reaction (min)	Order of reaction	Insulin released m equiv / dry g	Fraction of absorbed insulin released (%)	Time taken to complete 50% reaction (min)	Order of reaction
'*CMC* (*a*)'	0 25	1 50 H 1 60 Na	0 072	29	<1	2	0 072	100	<1	2
'*CMC* (*b*)'	1 0	1 78 H 2 57 Na	0 308	31	2 5	2	0 205	67	1 5	2

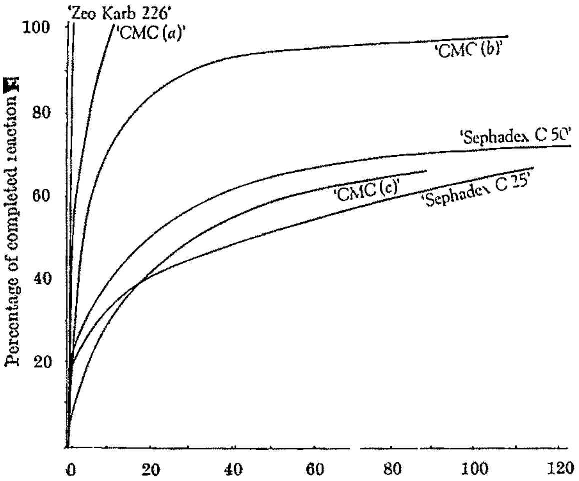

Fig 1 Absorption of insulin on carboxylic exchangers

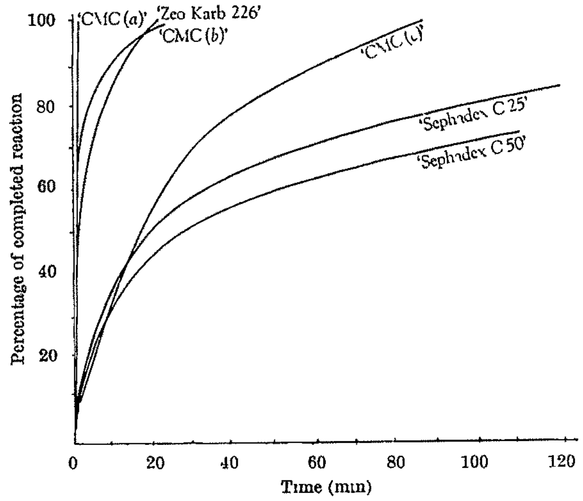

Fig 2 Desorption of insulin from carboxylic exchangers

The water regain value, together with the relationship between the rates of absorption and desorption, indicates the resistance of the system to changes in volume with changing ionic form and hence to the dimensional stability of the exchanger

The order of the reaction provides an indication of the manner in which the ion-exchange sites are disposed in the exchanger, an order of 2 being consistent with reaction at readily available surfaces

The relative rates of absorption and desorption of insulin are further compared in Figs 1 and 2

Cellulose, in its natural state, possesses a type of molecular structure which is able to confer unique characteristics on later derived ion-exchange materials In contrast to various other types of synthetic ion exchangers which offer a more or less uniform network of molecular pores, it is possible to prepare ion-exchange celluloses which are characterized by aggregates of polysaccharide chains in various states of order and disorder, within and between which are located pores of widely differing size The largest pores are readily accessible even to polyelectrolytes At the same time the regions of higher order provide a supporting matrix which effectively controls expansion and contraction of the pore structure, enabling high accessibility to be combined with high dimensional stability

The results recorded in Table 2 reflect the fundamental structural differences between synthetic resin, cross-linked dextran and cellulose ion-exchange derivatives

It is significant that the experiments were carried out using pre-cycled, undried exchangers Although the hydroxyl character of cellulose and dextran matrices is an asset in the application of these materials to large ion investigations this same character necessitates special precautions in the use of the exchangers For example, intermolecular hydrogen bonding induced on drying the exchangers tends to create inaccessible regions in the structure It is because of this that it is necessary to pre-cycle the exchangers prior to use and to retain them in a swollen state

The highly cross-linked, high capacity 'Zeo Karb 226' with its backbone of hydrophobic polymer chains is virtually inaccessible to the insulin ion Exchange is confined to the near surface of the resin particles Thus, absorption of insulin, accounting for only 0 4 per cent of the nominal capacity of the exchanger, is completed in less than a minute Subsequent desorption of even this small amount of insulin at pH 2 is relatively slow and incomplete, however, due presumably to the de-swelling of the surface structure on conversion to the hydrogen form Low accessibility, low dimensional stability and resultant irreversible absorption combine to characterize the application of a synthetic resin of this type to problems involving insulin or larger ions

In the 'Sephadex' ion exchangers the hydrophobic backbone of the resin has been replaced by a hydrophilic structure The effect of this hydrophilic backbone on the swelling of the exchanger in aqueous media increases the accessibility of the structure to large ions Thus, in spite of lower nominal capacities the 'Sephadex' exchangers absorb larger quantities of insulin than the 'Zeo Karb 226' (Table 2). Penetration of the insulin into the internal structure of the exchanger is reflected in the slow rate of absorption The relatively low dimensional stability of the 'Sephadex' exchangers, however, results in an initial rapid absorption being followed by a relatively slow uptake of insulin as the exchanger de-swells Desorption of insulin from the 'Sephadex' exchangers follows a pattern similar to the absorption 'Sephadex *C* 50' is more highly swollen than 'Sephadex *C* 25' and is also less stable dimensionally The effect of swelling changes on absorption and desorption of insulin is particularly marked with this exchanger The rate of desorption of insulin from Sephadex *C*.50' is slower than that of the initial absorption process for this reason

In dextran-derived exchangers, therefore, the occurrence of a hydrophilic backbone structure increases the accessibility of the exchanger to insulin relative to that of a synthetic resin exchanger The retention of the more or less uniform molecular porous network of a gel structure, however manifests itself in relatively large dimensional changes during absorption and desorption of large ions This effect is particularly pronounced in the higher swelling variants and leads to relatively slow kinetics, particularly during desorption A fraction of the insulin thus has the appearance of being preferentially held on the exchanger

Viewed in the foregoing context, cellulose exchangers differ in their performance in being able to combine, by virtue of their unique molecular structure, high accessibility with high dimensional stability The extent to which these characteristics are shown is dependent on the ion-exchange capacity of the exchanger as is indicated in Table 2 The percentage of insulin desorbed at pH 2 from the '*CMC*' variants shows that selectivity for insulin increases with increasing ion-exchange capacity The higher selectivity of '*CMC* (*c*)', however, is achieved at the expense of accessibility and kinetics Table 2 illustrates the similarity between '*CMC* (*c*)' and the 'Sephadex' exchangers in relation to selectivity for, and rates of absorption and desorption of, insulin A significant difference in performance is shown in Figs 1 and 2, however The higher dimensional stability of the cellulose exchanger gives rise to more regular rates of absorption and desorption of insulin. It is consequently easier to remove the more deeply penetrated insulin from cellulose compared with cross-linked dextran exchangers even when all other features such as total absorption, capacity and selectivity are the same.

Significant departure from synthetic resin and cross-linked dextran exchanger type behaviour, as recorded in Table 2 and Figs. 1 and 2, is shown by '*CMC.(a)*' and '*CMC.(b)*'. Because of their relatively low capacity the selectivity of these exchangers for insulin, particularly that of '*CMC.(a)*', is lower than that of the previously discussed exchangers. The influence of this lower selectivity on total absorption of insulin is compensated for by the higher accessibility and faster kinetics on the lower capacity '*CMC*' variants. The performance of '*CMC.(a)*' and '*CMC.(b)*' reflects those characteristics which are peculiar to cellulose-based exchangers and which could not be reproduced on the other particular exchangers investigated. Rapid absorption and desorption. relatively high accessibility and the lack of any tendency for irreversible absorption even when maximum loadings are used are significant features arising from the results recorded on these two exchangers.

To sum up, therefore, the comparative results obtained in this investigation have indicated that although a hydrophilic matrix is a highly desirable feature of an exchanger used in large ion studies, for more versatile and efficient use, under both batchwise and chromatographic conditions, an exchanger must also possess specialized structural features at a molecular level. A combination of these features has been found to exist in selected cellulose exchangers.

We thank the Directors of W. and R. Balston, Ltd., for permission to publish this work.

LAVA TUNNELS AND SOME POSSIBLE GAS EFFECTS IN BUFUMBIRA

By E. J. WAYLAND, C.B.E.

MR. L. A. J. WILLIAMS'S account of "Lava Tunnels in Suswa Mountain, Kenya"[1] recalls records of similar phenomena in Bufumbira, the Uganda embayment of the remarkable Birunga volcanic field (Virunga of the Belgians) lying to the north of Lake Kivu in the Western rift valley of East Africa.

The following hitherto unpublished facts are embodied in the first of two field journals covering my preliminary reconnaissance of the southern and western portions of the Uganda Protectorate, undertaken more than forty years ago.

Under the sub-head "4.4.19, Exploration of Kegezi Camp" it is recorded that a line drawn from the right front corner of the camp compound towards Bihungi and on to the highest peak of Chansi crater (Chansi and Mount Muhavara appear to be one and the same) passes through a tall, conspicuous and solitary tree by the side of which is the mouth of a large lava cave, or tunnel, running below the flat surface of the ground. I went along this tunnel for about eighty yards, at which point it becomes very narrow, low, damp and infested with bats. Its direction parallels the strike of the high sedimentary country to the east of it (S. 15° E.). In numerous places lava tunnels have responded to structural control (lines of strike and jointing) imposed by pre-lava rocks well below them. A case in point is provided by the Kegezi tunnel, as for convenience I call the one considered here.

In vertical section the tunnel, where I traversed it, is nearly semi-circular with plenty of headroom. There are about 6 ft. of soft deposit on its floor (black at bottom and top with a white zone in the middle). A grindstone, presumably of no great age, was unearthed near the top and a few microlithic artefacts were near the bottom. Among the latter was a beautifully made 'lunate', almost certainly belonging to the Wilton culture.

It seemed obvious that the tunnel was in a measure consequent on differential chilling of flowing lava. Temperature control at the ground beneath the molten rock and at the interface between the latter and the covering air could provide the required primary conditions at opposing surfaces and, given a slope sufficient to prevent stagnation, provide a temporary flowage of lava between solidified sheets of itself. But this would not make a tunnel, for the molten lava would in its turn solidify sourcewards. Thus would the stony sheets thicken and coalesce; and it is not difficult to visualize conditions in which the flow of sub-surface lava would cause sheet-collapse of a solidified and jointed zone above it. Such results are seen.

Clearly, a factor conducive to tunnel production in these circumstances would be a channelled ground surface disposed to increase the speed of lava flow to a maximum controlled by viscosity and temperature along its course, and indeed beyond its beginning to a starting point of lava movement until the source-supply was abolished by solidification or, more likely, by cessation, temporary or otherwise; but the channelled molten rock would continue, for a while, its onward journey, only to be frozen in its turn; a long gap, a tunnel, in fact, would thus appear between the proximal and distal portions of the once recalcitrant sub-surface lava stream.

Apart from penecontemporaneous additions such as lava stalactites of which very few were seen in the Kegezi tunnel, its walls and roof are smooth.

Old tunnel entrances are in most cases concealed by vegetation, and because they are unassociated with tip heaps they are not easily found. The Duke Adolphus Ferdinand of Mecklenburg, who, with his exploring party, entered Birunga (Virunga) in 1907, states that:

> "Spacious caverns formed under the crust of the lava streams have remained to the present day. We searched around for them, and crept into some of them so as to inspect the interiors. The entrances mostly lie concealed under shrubbery, and it occasionally takes a long time to find an opening."[2].

One is moved to ask, "Have any of these tunnels been put to sustained use?". At least one in Bufumbira has functioned as a vault. It was seen to house an astonishing number of human bones, some of which are deeply patinated and possibly of great antiquity. It is conceivable that they may have been collected as bones, from elsewhere.

I was shown this communal mausoleum, for the place has imposing features, under oath of secrecy; nor was I permitted to remove any bones—an unfortunate restriction, for it became my practice to send all crania and pieces of human skull that I chanced to come across or to discover to Sir Arthur Keith.

I have visited the Bufumbira country and the Belgian Congo (Birunga) beyond it several times, but nineteen years were to elapse after the first occasion before I was privileged to behold lava tunnels in action.

Mount Nyamlagira (summit 10,026 ft. above M.S.L. at Mombasa and rising 5,000 ft. above its base) in Birunga had awakened again, as it does from time to time, to belch forth lava and all the products of seeming ill temper to which volcanoes are prone. J. Verhoogen, the volcanologist, was flown out from Belgium to study the phenomena[3], and I, with similar intent, hurried westwards.

Here I must restrict my remarks to lava tunnels and to some ancillary matters. To recall all the experiences and observations that emerged from my stay on the Mountain would be to fill a book; they begat, however, at a later date much detailed field work, mapping and profound petrological enquiries, all of which matters are set forth in two official volumes and several scientific papers[4].

There is a tendency for the tops of lava tunnels to drop in for a few yards from place to place, and in some cases for extended stretches to do so, thus producing lava rifts which have sometimes been wrongly attributed to tectonic activity. Commonly, however, in Birunga, bridge-like roof-remains provided chances to stand over the thalweg of a lava stream, thus to peer down and watch the incandescent turmoil until driven away by unbearable heat. Through one such opening on Nyamlagira the racing magma passed over a point where in other circumstances a small waterfall might have danced onwards, so to say, to the tune of its own music; but now molten lava poured over the site in ominous treacly silence. A rock tossed into the glowing stream occasioned no splash. It was rapidly absorbed and ceased to exist.

There are numerous large caves of one sort or another in Uganda. Some of them have been used for refuge during tribal raids or wars; others, or the same caves at different times, for impounding cattle, but I was unable to discover that they had been utilized for either of these purposes in Bufumbira. In Birunga, on the other hand, to continue the Duke of Mecklenburg's pronouncement:

"These caves served the Wanjaruanda not seldom as secret lurking places Even as late as 1906 Captain von Grawert had arrows showered upon him from the mouth of one of these caves whilst engaged on a punitive expedition."

Some of the tunnels, I was told, were shunned by everyone, but I did not learn why this was so. Perhaps it was for the same reason as certain of the Elgon caves were, and likely enough still are, avoided because of fear of revengeful wraiths or because they have been cursed by evil beings of malicious intent. In either case the result is said to be the same—a distressing illness ending, more often than not, in death.

The supernatural or occult can be discredited. Not so the sickness, it seems, for it is claimed to follow inhalation of certain airborne fungal spores. A similar explanation has on occasion been applied to ancient Egyptian tombs of sinister reputation.

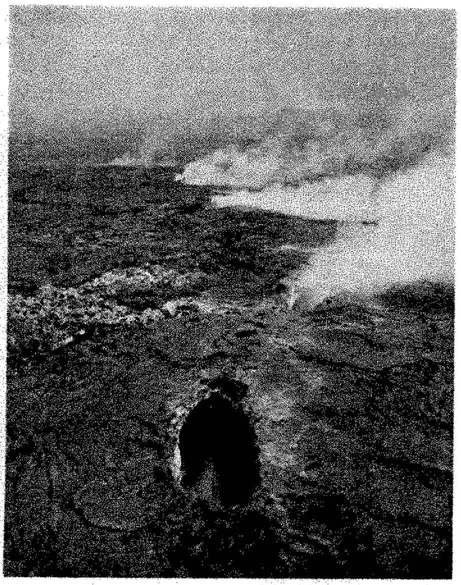

Fig. 1. A lava tunnel opened in four places by falls of roof. While three of the openings emit vapour, the nearest shows a breach to an older tunnel below it. The vapour-giving lava stream appears to have entered the lower tunnel at a spot between the third and the nearest roof collapse

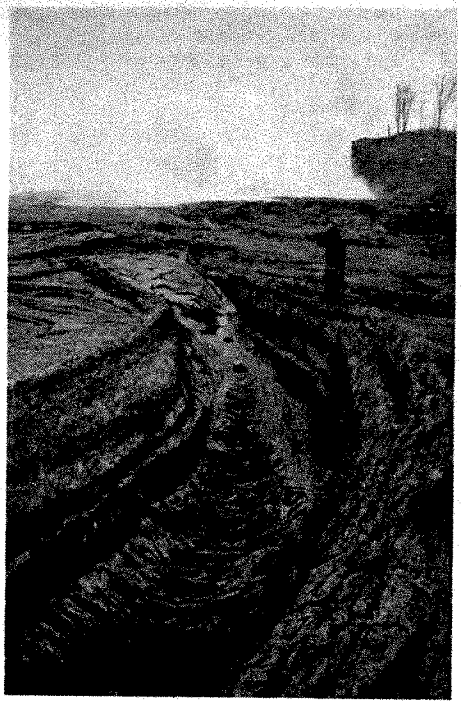

Fig. 2. A lava stream in an open channel produced by lengthy collapse of a lava tunnel roof

Williams writes: "Although the complete pattern of the Suswa tunnels is as yet unknown, it seems remarkable at first sight that they should have developed immediately above each other in successive lava flows. Such an arrangement is readily explained, however, because the dividing lava was thin, allowing the mobile central portion of the overlying flow to drain away through collapsed areas of its floor. Lava flow in open channels, if it ever occurred, probably played only a minor part in the development of these features, and formation of the earliest tunnels probably depended on unusual circumstances, such as extrusions of the lava over patches of hot ground which helped to keep portions of the flow mobile".

These may be unusual circumstances; certainly the claimed effect would scarcely have been anticipated. The patches of hot ground are unlikely to have been lineal unless they were themselves already channelled. Lava flows in open channels, by the way, are by no means unknown in the Bufumbira–Birunga field (Fig. 2).

Lava tunnels in other widely flung volcanic terrains are well known: some are almost famous. Williams goes on to say that such openings "have not been reported from surrounding areas in the rift valley where many of the volcanic rocks are phonolites and soda trachytes" (like those of Mount Suswa ?).

As already mentioned, the fluidity of a molten material depends in large measure on its viscosity: the higher the viscosity the lower the degree of fluidity of a lava, and the flatter the cone built of it. Nyamlagira, it may be mentioned, is a flat cone.

In general the viscosity of a lava is a function of the percentage of its silica. Phonolite and trachyte are silica-rich (about 60 per cent according to the type) and would not be expected to display a propensity to tunnelling, except where the molten rock was so canalized that gravity hastened its progress while the upper and lower portions froze solid, after the manner already explained.

Lavas would seem to have a tendency to shrink on cooling. Hence the 'moat' to be seen on a number of volcanoes, Suswa included, surrounding more or less completely the consolidated lava columns which otherwise fill their craters.

Nyamlagira provides an instructive example, and vividly I recall the occasion when a small hut-like construction which had been erected over a narrow part of the moat was suddenly and unexpectedly shot into the air, together with its occupant, by reason of a singular and powerful belch up the moat of hot gas and 'steam'. This unique missile landed, fortunately, clear of the gaping chasm, into a cushion of fine black volcanic dust. No bones were broken.

Owing to the comparative freedom of movement occasioned by the presence of the surrounding moat, a solidified central lava column, compelled by gas or ascending magma, or by both, may rise high above the volcanic mass—like the spine of Mount Pelée.

But against thermal shrinkage in a cooling lava (setting aside for convenience paramount glass production, obsidian, for example) one must place expansion resulting from crystallization of most of its constituents as they congregate to form mineral species. These opposing states (the introverted strain of shrinkage, or I.S., and the extroverted strain of crystallization, or E.S., one might call them) will balance at one stage, or at a few stages only of the cooling process.

If the top and bottom of a lava flow have solidified sufficiently to permit of tunnel-formation, surface effects may occur vertically above a stretch wherein the tunnel-lava has been halted and has filled all available space in its vicinity. Should crystallization begin concurrently with cooling (it will scarcely start impressively before it) no consequent surface phenomena will result, provided that the cooling and the crystallization proceed *pari passu*, and that the introvert and extrovert stresses cancel out (I.S. = E.S.). When E.S. is effectively greater that I.S. it will be reinforced from below in consequence of thrust occasioned by the unyielding bottom and a lineal swelling may appear at ground surface and split longitudinally. When E.S. is effectively less than I.S. a channel or a shallow lineal collapse may occur revealing no tunnel beneath it.

The trace of a lava tunnel, or tube, is likely to have been the thalweg of a relatively flat valley-form hollow. Of no great size but very much wider than the molten stream that later came to fashion a tunnel, the hollow-way or valelet may or may not have positioned a predisposing water channel in pre-lava days. In either event, the result would have been very much the same. Had the lava filled much or all of the hollow-way, melt-chilling would have been vertically convergent and progressive, and a similar convergence would have operated laterally in accordance with lava thickness; so, too, with crystallization. Over the tunnel site E.S. would additionally operate slowly downwards, but it would not deform the roof-shape of the developing tunnel. None the less, a shallow linear sag might well appear at surface later to initiate another tunnel if and when a further copious lava spread occurred. Thus may one tunnel be superimposed, wholly or in part, above another.

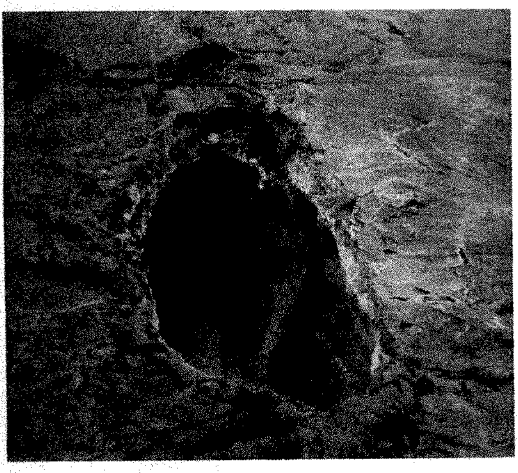

Fig. 3. Close view of nearest collapse depicted in Fig. 1

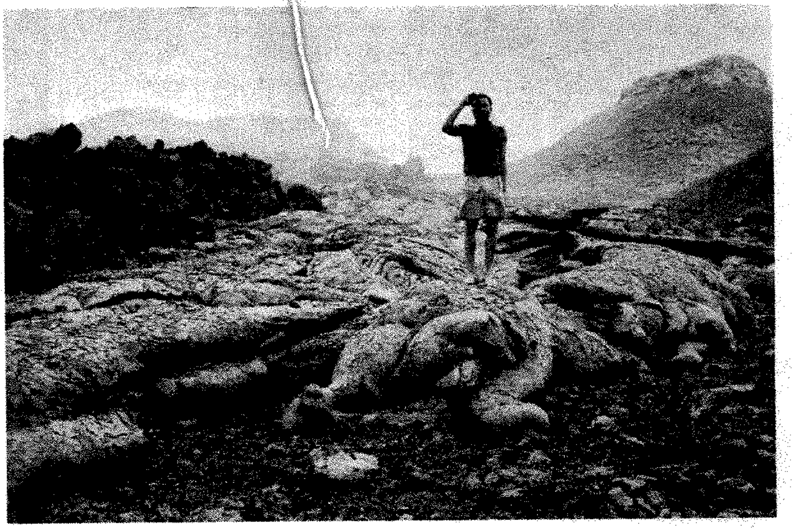

Fig. 4. Lava 'slugs'

(All photographs—unofficial—by the late A. D. Combe, of the Geological Survey of Uganda)

Williams writes of minor explosions caused by the combustion of gases generated from inundated vegetation. Nothing appears to be known of this phenomenon in the Bufumbira–Birunga field, but in this category perhaps may be placed some obscene-looking bubbloid excrescences, suggestive of connubial slugs of enormous proportions, occurring on Nyamlagira and some associated volcanoes. When first I clambered on to one of the 'slugs' I crashed through the top of it, but not to descend, as momentarily I feared I should, into an inferno below, but to solid ground at about 4 ft. 6 in. (Fig. 4).

There is much evidence of true volcanic explosion and gas activity in Bufumbira–Birunga. The following is extracted from my notes of April 3, 1919.

"Near Chanse crater there are many hummocks of lava without craters which require explanation. They suggest bubbles, but are up to 20 ft. in height; each has a base diameter of about three times the vertical measurement." Much bigger examples were later discovered, some breached to the base by emergent lava.

It was later discovered that these mamilliform excressions are not formed from lava but made up of ash and scoriæ of extremely frothy and pumiceous lava. Although not titanic bubbles, they represent a phase of an explosive episode. Thus they differ widely from the mamelons of Reunion Island and some of the puys of the Auvergne, to quote two well-known examples of lava plugs.

There is evidence in plenty that explosive volcanic action was widely developed in the Bufumbira–Birunga field. Indeed, it appears to have been the initial stage of the volcanicity.

MULTIPLE SOLUTIONS OF X-RAY DIFFRACTION DATA

By Dr. R. K. BULLOUGH

Manchester College of Science and Technology, Manchester, 1

It has been known for many years[1-3] that two quite different configurations of atoms can show the same X-ray scattering pattern. Equivalently the Patterson interatomic vector diagram can have two equally good alternative solutions. Such solutions are homometric. Weighted periodic or non-periodic homometric pairs of point sets (that is, sets with Dirac δ-functions of positive integral weight z_i at points $\mathbf{x}_i$) exist in any number m of dimensions[3,4]: it is known[3] that if two sets each of total weight Z (assumed integral) constitute a homometric pair in q dimensions they may be used to derive non-trivial homometric pairs of weight Z in $m > q$ dimensions and it has been shown[4] that they may also be used to generate homometric multiplets with 2^s members (that is, of order 2^s) and weight Z^s in $m \geqslant qs$ dimensions. The investigation of one-dimensional homometric multiplets therefore has an important bearing on multiple solutions of X-ray data in 3 dimensions.

In one dimension it is now known[5] that homometric r-tuplets exist for sets of $n + r$ points of equal weight for arbitrary $n, r \geqslant 2$. It follows: (1) that there are sets which constitute homometric multiplets of order $Z-2$ for every $Z \geqslant 4$; (2) that there are, therefore, multiplets of arbitrarily large order, that is, it is possible to construct one dimensional vector sets with as many equally good solutions as one pleases. From multiplets of order r and weight Z in one dimension can be constructed multiplets of order r^m and weight Z^m in m dimensions. It is evident here that although the maximum order of a multiplet is without limit the large order is achieved only at the expense of increasing the total weight Z—and this proves to be true whether this is done by increasing the total number of points N, or their individual weights z_i, or both.

It has been proved by me that for a given total integral weight Z the maximum order R of any multiplet of point sets is bounded above. In so far as the restriction to ('continuous') δ-function point sets and vector sets restricts the available solutions of the latter to ones approximately conforming to the known physical characteristics of a system of discrete atoms of positive density the existence of the number R demonstrates the existence under these physical constraints of a solution (albeit possibly still multiple) of the 'phase problem'. In contrast it has been proved that, if solutions are restricted only by a condition of continuity, R does not exist and the maximum multiplicity is not bounded: a further condition that solutions be everywhere positive is not of itself then sufficient to imply the existence of R. Since R exists for δ-function point sets and, as noted here, is $\geqslant Z-2$, R is an increasing function of Z for these sets. Clearly it is important for the assessment of the validity of crystal structures determined by X-ray diffraction to know how fast R increases with Z: it is also important to know how R is reduced by the additional constraints offered by symmetry, or by other physico-chemical information, or, for example, by the direct determination of a few phases.

The chance of any structure occurring in Nature being one of several homometric alternatives is probably very small; but errors in observed intensities and from their finite number could mean that for large enough Z the observed Patterson diagram differs from a vector diagram with multiple solutions by less than the uncertainty in the observed diagram. We shall need to know more about the dependence on the number Z of each of the errors in Patterson peak positions, of R, and of the number $Q(r, Z)$ of vector sets with precisely r solutions, to form a valid conclusion; but the fact that $R \geqslant Z-2$ suggests how dependent on other physico-chemical information may be the structures of large molecules elucidated by X-rays. In particular it seems at least possible that, because any observed vector diagram probably 'almost always' has a unique solution, that solution would always be obtained by any routine method of solution at the expense of a possibly very different solution equally acceptable when the error in the observed intensities is included.

The practical implications of the dependence of R on Z when the only constraints are those offered by δ-function point sets must be drawn cautiously. Nevertheless it seems of sufficient interest to report that, for one-dimensional sets of Z points of equal weight, R is almost certainly not asymptotically equal to $Z-2$ as it was earlier thought to be[5]. Indeed, the brief remark in the earlier paper[5] must be withdrawn because it is in fact easy to construct multiplets of equal points for which r increases not as Z but essentially as Z^2. It can be proved that $R = 1$ for $Z < 4$; $R(4) = 2$ and $R(5) = 3$; but $R(6) \geqslant 5$ as the example (2) below shows and its precise value is not known.

One of the only two families of pairs which can be constructed for $Z = 4$ is the periodic pair with co-ordinates[5]:

$$S_1 = (0, 1/13, 3/13, 9/13);\ S_2 = (0, 1/13, 4/13, 6/13) \quad (1)$$

with a unit cell of unit length and each point chosen for convenience with unit weight. This pair has a remarkable vector diagram consisting of 12 points of unit weight at 1/13, 2/13, . . . , 12/13, and with a point of weight 4 at the origin. For $Z = 6$ the following analogous pentuplet:

$$\begin{aligned} S_1 &= (0, 1/31, 3/31, 8/31, 12/31, 18/31)\\ S_2 &= (0, 1/31, 4/31, 6/31, 13/31, 21/31)\\ S_3 &= (0, 1/31, 8/31, 11/31, 13/31, 17/31)\\ S_4 &= (0, 1/31, 4/31, 10/31, 12/31, 17/31)\\ S_5 &= (0, 1/31, 3/31, 10/31, 14/31, 26/31) \end{aligned} \quad (2)$$

exists; the vector diagram has a zero vector of weight 6 and vectors of unit weight at 1/31, 2/31, . . . 30/31. The order r of this type of multiplet seems to increase about as $Z^2/10$. I have calculated them for Z = 3, 4, 5, 6, 8, 9, 10, 12, 14, 17 and find corresponding multiplet orders r = 1, 2, 1, 5, 6, 4, 6, 18, 20, 6; $r = 0$ for $Z = 7$, that is, there is no set at all of this type. It is not clear from this that r is even an increasing function of Z: however, each r satisfies the remarkable formula:

$$r = \varphi(M)/6k \quad (3)$$

where $M = Z^2 - Z + 1$, $Z - 1 = p^k$ with k an integer and p always prime, and $\varphi(M)$ is Euler's number theoretic function—the number of numbers prime to and less than M. It is easily proved that $6k$ is always a factor of $\varphi(M)$ and I have also proved (1) that $r \leqslant \varphi(M)/6k$; (2) that there are certainly $\varphi(M)/6k$ 'generators' of (probably distinct) sets with vector diagram ($1/M$, $2/M$, . . . , $(M-1)/M$) and a zero vector with weight Z (the 'generators' are distinct cubics irreducible over a Galois field of characteristic p: the problem is to show which distinct cubics generate distinct homometric sets); (3) that the 'average order' of r increases with Z: all the evidence suggests the truth of (3). The 'average order' of $\varphi(n)$ is $6n/\pi^2$, so that the normal order of r is (probably) at least $\sim Z^2/\pi^2 k$ and could be slightly higher if the numbers M contain a high density of primes for which $\varphi(M) = Z^2 - Z$ Examples are $Z = 18$, $M = 307$ prime and r (probably) 51, or $Z = 42$, $M = 1723$ prime and r (probably) 287, or $Z = 60$, $M = 3541$ prime and r (probably) 590

These sets are somewhat divorced from reality because they show a dearth of short bonds (it would be interesting to know the reduction in R if point sets are required to satisfy additional conditions on the relative distribution of vector magnitudes), but this apart they seem important to me because. (1) they show distributions of vectors spread uniformly over the unit cell and except for the dearth of short bonds and especially when convoluted[6] with a (Gaussian or other) peak of finite width approximate to the featureless vector diagrams of many organic molecules, (2) any particular homometric multiplet of weight Z and order r is a degenerate example of a large class of multiplets of weight ZZ_0 ($> Z$) and order r (ref 6), (3) they seem capable of giving a clearer idea of 'what sort' of multiplicity r of solution we can expect for large values of Z We may add that these particular sets have considerable number theoretic interest, they all constitute examples of 'finite projective geometries' and as such were first examined by Singer[7] to whose key theorem my method of calculation of the multiplets for $Z = 8$, , 17 is essentially due Singer himself also calculated some of these sets and in effect conjectured the remarkable formula (3)

Examination of some of these sets suggests that each can exist when and only when all its points have equal weight In this they show some indication of achieving an optimum arrangement with maximum multiplicity so that (3) may indeed be the precise value of R when $Z = p^k + 1$ On the other hand, if the points can take on unequal weights the possibility for multiplicity with a fixed number N of points is enormously increased it has already been reported[5] that homometric pairs of sets of the same or different unequal weights can then exist, but we must add here that multiplets of only three points exist and with order as large as one likes Again the order can be increased only at the expense of increasing Z, the total (positive) integral weight of the 3 points This example indeed is only of theoretical interest since typical data are $r = 2$, $Z = 168$, $r = 3$, $Z = 1157$, $r = 4$, $Z = 8088$, and $Z\ (r = r_0 + 1) \approx 7 \times Z\,(r = r_0)$ but from it can be constructed almost homometric multiplets with integral weights of practical significance Moreover with larger numbers of points we might expect similar behaviour for a smaller average weight of each point

If rational non-integral individual weights are permitted multiplets of arbitrary order and three points can be constructed for any Z one cares to choose As the order increases for any fixed Z, solutions remain discrete but become progressively 'closer' From these can be constructed, of course, homometric multiplets of three Gaussian (say) functions of arbitrary order and with different total non-integral density in each comparable 'atom' if the atoms are not restricted to pre-assigned or similar shapes possibilities of multiplicity again increase This again forcibly illustrates the fundamental importance of approximately positive integral (or at least positive and finitely discrete) atomic numbers and essentially spacially discrete atoms of similar or *a priori* known shapes to the existence of a solution of the phase problem It is easily proved that all continuous periodic sets can be deformed continuously to continuous sets by infinitesimal deformations which leave their convolution stationary, and even by finite deformations other than simple finite translations which leave their convolution invariant it follows that R does not exist in this case In contrast it has been proved that it is never possible to deform a non-negative point set of integrally weighted δ-functions continuously by other than translation and leave its vector diagram unchanged Indeed. in this case a majority (in some sense) of sets of data have a unique solution (with the necessary corollary that a unique phase determining method then exists) Nevertheless even in this very restricted but practically important case there remain multiple solutions of arbitrary order some of which are reported here, and if the restriction to atoms of the same shape is removed so that they cannot be represented by δ-functions the theoretical possibility of the existence of multiplets of an at least enumerably infinite order has still to be excluded This might put some limitation on the validity of the determination of peak shapes and thermal motion by X-rays It would be interesting to know what minimal sets (if any) of conditions implicit in the physical situation are sufficient for the proof of the existence of an always unique or at most boundedly multiple solution of the X-ray 'phase problem'

MAXWELL–MICHELL THEORY OF MINIMUM WEIGHT OF STRUCTURES

By PROF T M. CHARLTON

Department of Civil Engineering, The Queen's University of Belfast

IN 1869 [1] Maxwell stated the theorem "In any system of points in equilibrium in a plane under the action of repulsions and attractions, the sum of the products of each attraction, multiplied by the distance of the points between which it acts, is equal to the sum of the products of the repulsions multiplied each by the distance of the points between which it acts" He applied this theorem to plane pin-jointed frameworks as follows ' In a plane frame, loaded with weights in any manner, and supported by vertical thrusts, each weight must be regarded as attracted towards a horizontal base line, and each support of the frame as repelled from that line Hence the following rule

"Multiply each load by the height of the point at which it acts, and each tension by the length of the piece on which it acts, and add all these products together

"Then multiply the vertical pressure on the supports of the frame each by the height at which it acts, and each pressure by the length of the piece on which it acts, and add the products together This sum will be equal to the former sum If the thrusts which support the frame are not vertical, the horizontal components must be treated as tensions or pressures borne by the foundations of the structure, or by the Earth itself

"The importance of this theorem to the engineer arises from the circumstance that the strength of a piece is in general proportional to its section, so that if the strength of each piece is proportional to the stress which it has to bear, its weight will be proportional to the product of the stress multiplied by the length of the piece Hence these sums of products give an estimate of the total quantity of material which must be used in sustaining tension and pressure respectively "

Maxwell proved the theorem applied to frames by an argument using the concept of virtual work

In 1904[2] Michell deduced from Maxwell's theorem that "A frame therefore attains the limit of economy of material possible in any frame structure under the same applied forces, if the space occupied by it can be subjected to an appropriate small deformation, such that the strains in all the bars of the frame are increased by equal fractions of their lengths, not less than the fractional change of length of any element of the space"

In the following paragraphs Michell's theory is explained in modified form by means of the principle of virtual work, which is first explained in detail

If any system of forces in equilibrium is imagined to be subjected to any system of displacements which is compatible with the geometry of the force system, the net work done during the imaginary process is zero This is the principle of virtual work and it depends on the law of conservation of energy Application of the principle to frameworks is, perhaps, most easily appreciated by reference to pin-jointed frameworks Each joint of a loaded framework is in equilibrium under the influence of forces exerted by bars and external forces (loads or reactions), so that for an arbitrary imaginary or virtual displacement of a joint which is compatible with the geometry of the loaded framework

$$\Sigma f\Delta_B + \Sigma F\Delta_L = 0 \qquad (1)$$

where f is the force exerted by any bar connected to the joint, F is an external force acting on the joint, Δ_B and Δ_L are the components of the virtual displacement of the joint in the line of a bar and external force, respectively, and the summations embrace every bar and external force at the joint It should be noted that the products $f\Delta_B$ and $F\Delta_L$ are positive when the sense of the force and displacement component is the same Also the limit on the nature of virtual displacements is set by the condition of their interrelation on the basis of the geometry of the loaded framework, that is, they must not be such that gross distortion of the loaded framework is implied

The virtual work equations of all the joints of a framework may be added to give the virtual work equation of the whole, as follows

$$-\Sigma fel + \Sigma Fed = 0 \qquad (2)$$

in which the summations include all bars and all external forces, respectively Now the virtual work of the bars is expressed in terms of their forces and virtual changes in length, *el*, where *e* is a small fraction and the minus sign in equation (2) is to denote work done on a bar when it is subjected to a virtual change in length of the same sign as the force which it exerts, for example, virtual extension of a bar in tension The virtual displacements of the external forces F (loads and reactions), *ed*, are in the form of a fraction *e* times a length *d* which specifies the point of application of the respective force

Consideration of equation (2) indicates that if the system of virtual displacements of a framework is such that the loaded framework is imagined to shrink uniformly so that the same fraction *e* is applicable throughout, then

$$\Sigma fl = \Sigma Fd \qquad (3)$$

This is in accordance with Maxwell's concept for the purpose of proving his theorem applied to frameworks, as set out in the first paragraph

It is clear that for a definite system of loads and reactions the points of application of which are defined, the quantity on the right-hand side of equation (3) is constant, say, C An infinite variety of structures can, however, be used to transmit the loads and the fact that Σfl is the same for all of them is the salient feature of the analysis in relation to the least-weight aspect

Michell writes equation (3) here as follows

$$\Sigma f_p l_p - \Sigma f_q l_q = C \; (= \Sigma fl) \qquad (4)$$

where now f_p is the numerical value of the tension in any tie bar of length l_p and f_q is the numerical value of the thrust in any strut of length l_q He then goes on to say that if P is the greatest allowable tensile stress and Q is the greatest allowable compressive stress, the least volume of material in any frame (among those suitable for withstanding the specified system of loads and reactions) consistent with security is

$$V = \Sigma l_p \frac{f_p}{P} + \Sigma l_q \frac{f_q}{Q} \qquad (5)$$

The condition for V to be a minimum is the same as that for the expression

$$2PQV - (P - Q)C \qquad (6)$$

to be a minimum because V is the only variable Substitution from equations (4) and (5) in (6) shows, however, that V is a minimum when

$$(P + Q)\{\Sigma f_p l_p + \Sigma f_q l_q\} \qquad (7)$$

is least That is, V is least when the arithmetical sum of the products of lengths of bars and their forces is least This means that of all the frames which could be constructed in the space bounded by the points of application of the loads and the reactions, that which has the least volume of material has the smallest arithmetical sum of bar force and length products (This condition follows directly from equation (5) if $P = Q$)

Michell proceeds to derive the condition for $\Sigma f_p l_p + \Sigma f_q l_q$ to be least His method is rather tortuous and abstract and it is replaced here by what is believed to be a more practical, if less general, approach

Confining attention to the problem of the framework with the least volume of material to support a specified system of loads acting at specified points, with the aid of a specified system of reactions, the 'space' available is defined by the points of application of the loads and reactions Now the virtual work of the loads and reactions due to specified virtual displacements of their points of application causing virtual displacements throughout the structural space such that no bar suffers a change of strain numerically greater than ε is a definite quantity W The virtual work of the bars of any framework in the space for which the virtual displacements are compatible with those specified for the loads and reactions must then be equal to W, in spite of the fact that the number of bars and geometry of each possible frame are different Thus

$$W = \Sigma efl \qquad (8)$$

(where the summation is, of course, carried out algebraically taking account of the signs of *e* and *f* and includes all bars) for each of all possible frames within the limits of the space

Having regard to equation (8), it appears that the frameworks for which each of the terms *efl* ($e \leqslant \varepsilon$) has the same sign, that is, ties subjected to virtual extensions, struts to virtual contractions, make up the range of frameworks with the smaller values of $\Sigma f_p l_p + \Sigma f_q l_q = \Sigma |f| l$ If, in addition, all the virtual strains of the bars can be increases of the same amount ε, it follows that $\Sigma f_p l_p + \Sigma f_q l_q = W/\varepsilon$ is the smallest possible value This means that a framework attains the limit of economy of material possible in any framework subjected to the same system of applied forces with specified points of application, if the co-ordinates of its joints with reference to any specified origin can be imagined subjected to small changes such that the strains of all the bars receive equal virtual increases (It is emphasized that strain is defined as a fraction an increase of strain implies additional extension or contraction depending on whether the bar functions as a tie or a strut) Although the analysis is presented with reference to plane pin-jointed frameworks the implications appear to be quite general

Kallman's Bipolar Negative Resistor

Kallman has described a bipolar negative resistance element using a few grains[1,2] or thin layers[2] of semiconductor material Later[2] he describes a technique using "plain iron wire" The purpose of this communication is to emphasize the elegant simplicity of the latter method, it is found possible to demonstrate many of his results in less than 1 h, using only readily available materials

About 60 cm of 20 s w g soft iron wire was cleaned with metal polish, and heated in air by a current transformer to just below red heat (judged in semi-darkness) After 25 min heating, the wire was removed, cut in half and connected to a 'Tektronix' type 575 transistor-curve tracer The wires were arranged to cross and touch lightly

After suitable adjustment of contact position and pressure, a curve (Fig 1) was obtained A rounded turnover at +4 8 V and 0 3 m amp is indicated followed by a negative resistance region up to 0 7 m amp A slope resistance of about −1 0 kΩ is obtained Further adjustment produced Fig 2, where the turnover is at about +5 5 V and 0 2 m amp, followed by a negative resistance region up to 0 7 m amp A slope resistance of about −1 7 kΩ is indicated, together with a burst of oscillation presumably due to energy storage circuits within the curve tracer being maintained in self-oscillation at the most active part of the negative resistance characteristic Both curves were taken with a 20 kΩ limiting resistance, the scales being 0 5 V/div horizontally and 0 2 m amp/div vertically The sweep voltage was a full-wave rectified 50 c/s sinewave

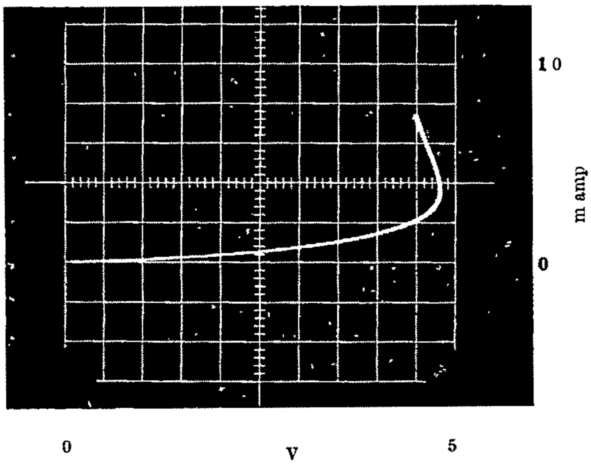

Fig 1

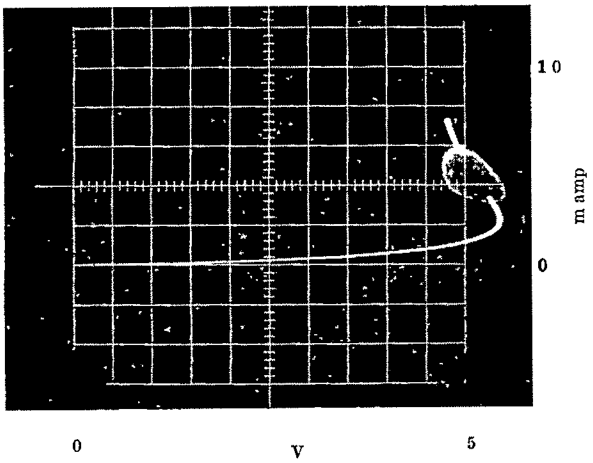

Fig 2

It was observed that a negative slope region could sometimes be formed from an all-positive-slope characteristic by suitable adjustment of the sweep drive, and that the negative slope could usually be destroyed by an increase of drive Kallman implies[2] that his characteristics were displayed with 1 2-kc/s sinewaves often gated to 60/sec 15 per cent duty factor so as to minimize heating

With the simple arrangement described here the characteristics shown were not as easily or stably produced or reproduced as suggested by Kallman, but the use of thinner wire (Kallman used 0·010 in diam) and a simple jig for adjusting the contact point and pressure should give a great improvement

Ultrasonic Excitation of Nuclear Magnetic Resonance of the Copper-63 and Copper-65 Nuclei in a Single Crystal of Copper

This communication reports the observation of the ultrasonic excitation of nuclear magnetic resonance in a metal single crystal Using the direct method of Bolef and Menes[1] it has been found possible to detect the additional attenuation of an ultrasonic wave due to the nuclear spin-level transitions for both copper-65 and copper-63 nuclei in a copper single crystal

The specimen was in the form of a half centimetre copper cube of purity 99 999 per cent, the cubic faces being aligned along the [100], [010] and [001] directions Because of its high electromechanical efficiency and good acoustic impedance match to copper, a barium-titanate ceramic (80 per cent $BaTiO_3$, 12 per cent $PbTiO_3$, and 8 per cent $CaTiO_3$) (refs 2 and 3) transducer was used This was in the form of a 0 47-cm disk, plated on one flat surface The fundamental thickness resonance frequency of the transducer was 5 0 Mc/s and it was possible to detect mechanical resonances of the specimen over a bandwidth of 4 Mc/s (ref 3)

The specimen was coupled into a Pound Knight Watkins marginal oscillator[4] using a double tuned transformer similar to that utilized by Bolef and Menes[1] The magnetic field was provided by a Newport Instruments electromagnet which was swept by applying a sweep voltage to the control circuits

The magnetic field was modulated at 250 c/s and synchronous detection was used

The specimen was driven at a mechanical resonance frequency (ν) of 5 223 Mc/s and the magnetic field was swept through the field value where the Larmor precession frequency of the nucleus concerned was approximately $\frac{1}{2}\nu$, that is, the ultrasonic excitation of transitions with magnetic quantum number changes of $\Delta m = \pm 2$ were observed The magnetic field was measured using a proton resonance magnetometer[5]

The line shape of the ultrasonically induced resonance broadens and the ratio of signal strength to ultrasonic power decreases with increasing transducer voltage, due to saturation of the nuclear spin-levels The unsaturated line width of the resonance is difficult to detect with the present experimental equipment but is approximately 25 gauss for the copper-63 resonance and 50 gauss for the copper-65 resonance Both lines are shifted to higher field values from that corresponding to the ultrasonic frequency equal to twice the Larmor frequency, by 85 gauss and 170 gauss respectively The relative sensitivities of the two lines can be estimated both from the strength of the absorption signal and the signal necessary to saturate the resonances The ratio in both cases is approximately 2 3 1, in agreement with the isotopic abundance ratio

Quantitative experiments are to be carried out with an improved experimental system, and the theoretical possibility that the line width observed may be due to exchange interaction between the nuclei via the conduction electrons[6,7] is being investigated

Dislocation Loops in Irradiated Iron

It has been suggested many times that the hardening of iron and steel on irradiation may result from the interaction of glide dislocations with dispersed clusters of point defects Two observations of such clusters using the technique of transmission electron microscopy have been reported in the literature[1,2] The work reported in this communication was undertaken to determine the crystallography of dislocation loops observed in pure iron

Thin foils of iron (approx 1000 Å thick) were irradiated with protons and Fe^+ ions of energy 150 KeV at temperatures in the range 20°–600° C Dislocation loops produced by this treatment had diameters ranging from 50 Å at low temperatures to 1500 Å at the higher temperatures The projected shape of the loops was elliptical in the proton irradiated foils and lozenge shaped in the foils irradiated with Fe^+ ions

A full crystallographic analysis has so far only been made for loops produced by irradiating with Fe^+ ions to a total dose of $\sim 1\ 7 \times 10^{16}$ ions/cm^2 at a rate of $\sim 4 \times 10^{14}$ ions/cm^{2}sec The specimen temperature was 500°–600° C

The crystallographic directions of the sides of the loop were determined by measuring the projected directions of the loop sides in a plane perpendicular to the electron beam On tilting the specimen through a large angle and repeating this procedure, the true directions of the sides were found Determining the directions of a pair of non-parallel sides gave the plane of the loop unambiguously All the observed loops were shown to be square, lying on $\{100\}$ planes with sides in the $<100>$ directions Sometimes loops were observed edge on and in these cases it has been possible to confirm that their poles lay very close to $<100>$

The Burgers vectors of the loops were determined uniquely by the standard diffraction contrast technique as pure $<100>$ edge dislocations[3] In the absence of any diffraction contrast within the loops which would indicate the presence of a stacking fault, it is likely that the Burgers vector is $a <100>$

The sense of the Burgers vector defines whether the dislocation loop has been formed by the condensation of vacancies or of interstitial atoms Methods[4,5] of determining the sense of b from diffraction contrast observations confirm that the loops result from the condensation of interstitial clusters

Estimates of the energies of various modes of condensation of point defects in the body-centred-cubic lattice indicate that the observed mode has low energy Other low-energy modes have $b = \frac{1}{2}a <111>$ since this is the slip vector, such loops may be sucked out of the foil by the image forces and hence would not be observed

METALLURGY

X-ray Asterism and Work-hardening in Crystals

This communication reports some observations pertaining to an experiment on the plastic behaviour of age-hardenable alloy single crystals The experiment formed a part of a senior year laboratory course and was intended to illustrate the strengthening effects due to well-known[1] precipitates in aluminium base copper alloys and also the fact that predictable lattice rotations are obtained for a given amount of tensile deformation in cases where only one slip system prevails[2] To this end it was planned that a number of crystals would be grown, their orientations determined, various heat treatments performed and elongations predetermined so as to give limited amounts of crystal rotation on the $<110>\{111\}$-system which could be checked by a second orientation determination after tensile deformation

It was found possible to grow single crystals of commercial 'Alcoa 2011' alloy by the strain anneal technique in spite of the high impurity concentration The nominal composition of this alloy is copper 5 5 per cent, lead 0 5 per cent, bismuth 0 5 per cent, silicon 0 4 per cent, iron 0 7 per cent, and zinc 0 3 per cent with the balance aluminium Half-inch diameter rod was rolled to a reduction of 57 per cent Tensile specimens were then machined, given a 5-min anneal at 550° C, pre-strained 2 per cent in tension and lowered into a 550° C salt bath at a rate of 0 5 in /h This produced single crystals throughout gauge-lengths several inches long Six crystals were given heat treatments which produce well-known[1] conditions in pure binary aluminium base copper alloys These were (*a*) Guinier–Preston zones of the first kind (*GP*I) The first coherent metastable decomposition product of the supersaturated solid solution—quench plus age 24 h at 130° C, (*b*) Guinier–Preston zones of the second kind (*GP*II)—quench plus age 24 h at 190° C, (*c*) θ′ (first over-aged, partially incoherent metastable precipitate)—quench plus age 24 h at 240° C, (*d*) θ, the equilibrium precipitate—quench plus age 24 h at 460° C, (*e*) θ, as produced by slow furnace cool from 550° C, (*f*) supersaturated solid solution—quench from 550° C Treatments *e* and *f* presumably yield θ and the supersaturated solid solution respectively Each crystal was then deformed in tension at 300° K in an 'Instron' testing machine at a rate of about 10^{-3} sec^{-1}

Pure binary aluminium–copper crystals, either as quenched or containing *GP*I or *GP*II zones, show crystal rotations characteristic of slip on only one system of the

<110>{111} type[2,3] In crystals containing θ′ or θ rotation is not detectable because sharp spots on X-ray patterns soon become smeared into arcs of Debye rings as plastic strain increases, indicating bending of lattice planes and probably simultaneous slip on many systems[2,3] In the present work, over-aged crystals (treatments *c*, *d* and *e*) behaved as expected in that they showed no lattice rotation, but unexpectedly crystals given zone hardening or quenching treatments (*a*, *b* and *f*) also behaved as just described

In all conditions the mode of fracture resembled that observed in binary aluminium–copper crystals in a zone-hardened condition[2,3], for example, extensive shear in a narrow band of {111} planes It is also of interest to compare values of critical resolved shear stress (CRSS) and rate of work hardening between 2011 alloy and binary aluminium–copper These comparisons follow

CRSS (kg/mm^2)

Treatment	*a* 24 h 130° C	*b* 24 h 190° C	*c* 24 h 240° C	*d* 24 h 460° C	*e* Furnace Cool	*f* Quench
2011 alloy	9 3	11 7	3 4	3 8	3 4	8 2
Al-3 85% Cu[2]	7 0	8 5	4 5	1 5	—	5 0[4]

Initial rate of work hardening $d\sigma/d\epsilon$ in kg/mm^2 from nominal stress versus percentage of elongation curves (σ versus ϵ)

Treatment	*a*	*b*	*c*	*d*	*e*	*f*
2011 alloy	0 94	0 40	2 34	2 80	1 87	0 35
Al-Cu avg [5]	------58---		----------360---------			

In summary it appears that for equivalent heat treatments 2011 alloy crystals are slightly stronger, work harden at about one-tenth the rate of zone hardened binary aluminium–copper crystals and one-hundredth the rate of precipitate hardened binary aluminium–copper crystals Neither the 'zones' nor the precipitates formed in 2011 have been studied in detail, however, it is possible that they produce higher coherency strains than their counterparts in binary aluminium–copper alloys, thus imparting higher strength The lower work-hardening rates are not understood, but it is possible that dislocations still simply shear through the 'zones', and concurrently produce new distortion of the slip plane as new interface is exposed This distortion could be responsible for the loss of the Laue spots and would also help explain why fractures resembled those of zone-hardened binary aluminium–copper crystals

The low rate of work hardening (1/100 of that of over-aged binary aluminium–copper crystals) and the observed mode of fracture for conditions *c*, *d* and *e* suggest that some precipitate shearing may also occur in the over-aged commercial material with dislocations more restricted to remain in one slip system than in the binary alloys Again, the loss of Laue spots could be due to the creation of increased distortions in the slip planes as further shearing of precipitates occurs rather than to slip on many systems

CHEMISTRY

Surface Conduction in Volatile Organic Crystals

The relatively good reproducibility found for the dark conductivity of crystals of π-electron molecules[1] does not apply to the smaller aromatic molecules ($\leqslant C_{14}$)

Thus for anthracene, $\Delta\varepsilon$ values lie between 1 1 and 2 7 eV, where $K = K_0 \exp(-\Delta\varepsilon/2kT)$ The highest value would be that expected on theoretical grounds (cf ref 1, Fig 4) Pulse photo-conduction in anthracene, known to be a bulk property, leads to a mobility value μ of 1 cm^2/V sec[2], hence assuming band theory, where $K_0 \sim 4\mu$ ohm^{-1} cm^{-1}, a $\Delta\varepsilon$ of 2 7 eV would give a conductivity $K = 10^{-16\ 4}$ $ohm^{-1}cm^{-1}$, at 400° K Since the observed dark conductivities, largely for polycrystalline specimens, are around 10^{-12} $ohm^{-1}cm^{-1}$, at 400° K, there is clearly a big discrepancy

We have accordingly measured the electrical conductivity of a number of small aromatic molecules, as plates about 50 $mm^2 \times 1$ mm thick cleaved from crystals grown by the Bridgeman technique from zone-refined material The measurements were carried out under nitrogen or argon in a silica and glass cell designed to reduce so far as possible the rate of sublimation of the crystal A field strength of 1,000 V cm^{-1} was used with electrodes of silver paste, mercury, pressed aluminium and platinum and all gave similar results Provision was made to attach a guard ring in such a way as to avoid appreciable distortion of the field between the electrodes Resistance values of 10^{16} ohms were measurable in favourable cases

It has been found that without a guard ring a single crystal showed very similar behaviour to a disk formed by compressing the crystalline powder The conductivity values were found to depend, to a certain extent, on the form and thermal history of the specimen, but within the limits of the rather poor reproducibility the results for anthracene and naphthalene agreed with the earlier values However, when a guard ring was attached to the single crystal, the values fell below the limit of measurement, corresponding to an upper value for the specific conductivity for the temperature concerned, as below

Anthracene	K	10^{-15} ohm^{-1} cm^{-1}	at 180° C
Naphthalene	K	10^{-15} ohm^{-1} cm^{-1}	at 70° C
m-Dinitrobenzene	K	10^{-15} ohm^{-1} cm^{-1}	at 70° C
Benzoic acid	K	10^{-15} ohm^{-1} cm^{-1}	at 120° C

Electrode contacts were checked since a measurable conductivity existed between electrode and guard ring in all cases On the other hand, polycrystalline disks and single crystals with visible cracks showed no reduction in conductivity on attaching the guard ring

It therefore appears that the conductivity earlier found for these crystals was a surface conductivity Because of their volatility at the temperatures of measurement the crystal surfaces will hold a certain coverage of adsorbed molecules of the substances concerned in a two-dimensional mobile layer If we suppose these surface molecules become ionized and form the charge carriers we may expect, because of the high mobility and entropy of the charge carriers, a very high value of K_0 This could explain the measurable conductivities K observed in spite of the high $\Delta\varepsilon$ values observed (4 eV for some benzene derivatives[1])

Such a mechanism for surface conduction would predict a possible parallelism between $\Delta\varepsilon$ and molecular sublimation energy which is in fact observed This mechanism clearly becomes impossible for large involatile molecules such as phthalocyanine, where there is now good evidence for bulk currents[3] Also it cannot hold for pure polymeric systems such as proteins, where the μ values (about 10^4 cm^2/V sec) although large are still within the possibilities predicted by band theory and its modifications[1] Where very high K_0's arise in polymeric systems we may suspect a surface transport of carriers by plasticizer or impurity molecules

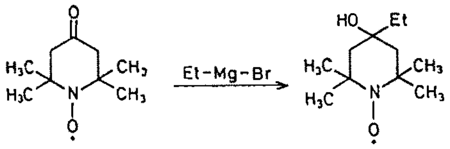
A New Organic Radical Reaction involving No Free Valence

THE discovery of a fundamentally new type of organic radical reactions involving no unpaired electron has been already reported[1–3] The work recorded here was concerned with a reaction between a free radical, triacetoneaminoxyl and the Grignard reagent The reaction proceeding with conservation of free valence yielded a new organic free radical with a hydroxyl group



After distillation in vacuum, the crude product appeared as a bright red oily substance readily soluble in water and in organic solvents Analysis by means of paper chromatography has shown that the oil was a mixture of two radicals 2,2,6,6-tetramethyl-4-ethyl-4-hydroxypiperidinoxyl and triacetoneaminoxyl (Fig 1)

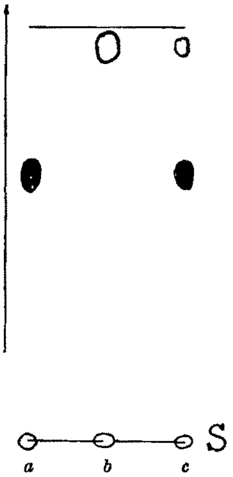


Fig 1 Paper chromatography (methanol acetone = 1 1) (a) 2,2,6,6-tetramethyl-4-ethyl-4-hydroxypiperidinoxyl, (b) triacetoneaminoxyl, (c) paramagnetic red oil

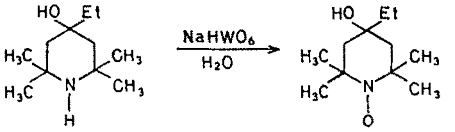
An individual paramagnetic compound with a melting point of 67°–69° was obtained on chromatographic purification of the crude product on aluminium oxide (found 0 480 per cent H (active), molecular weight 199 4, spin/mole $5\ 0 \times 10^{23}$, calculated 0 503 per cent H (active), molecular weight 200 3, spin/mole $6\ 0 \times 10^{23}$)

The new free radical represented an orange-yellow crystalline compound, soluble in water and in organic solvents, suffering no change for a year under the usual conditions

The ultra-violet (λ_{max} 227 and 235 mμ) and infra-red absorption spectra (Fig 2) were found to be identical to those of 2,2,6,6-tetramethyl-4-ethyl-4-hydroxypiperidinoxyl obtained by direct catalytic oxidation of 2,2,6,6-tetramethyl-4-ethyl-4-hydroxypiperidine by the scheme



The electron spin resonance spectrum of the crystalline radical represented a singlet type curve When the sample was solved in benzene, it turned into a triplet similar to the initial ketone radical spectrum (Fig 3)

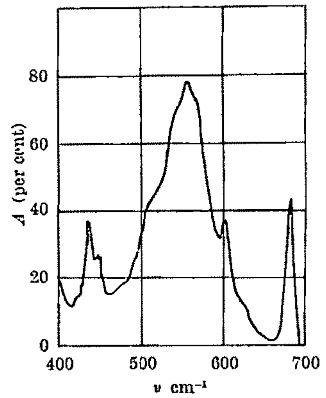


Fig 2 Infra-red spectrum of a solid free radical

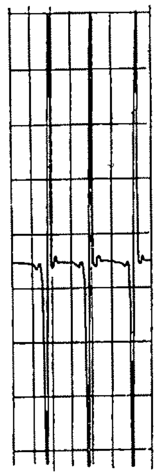

Fig 3 Hyperfine structure of a free radical electron spin resonance spectrum

The low-intensity doublets in the hyperfine structure of the spectrum (splitting of 5 4 gauss) seem to be due to an admixture of a natural carbon-13 isotope (spin 1/2)

A Direct Hydrocarbon/Air Fuel Cell

A CONSIDERABLE amount of effort is being expended at present to develop fuel cells capable of burning hydrocarbons directly and efficiently to carbon dioxide and water Most of the work so far has been confined to temperatures below 100° C using sulphuric acid as the electrolyte and platinum metals as the catalytic surface Under these conditions it has been possible to demonstrate current densities of up to 10 or 20 m amp/cm² at very low cell voltages, leaving in considerable doubt the feasibility of making efficient working devices

We have carried out investigations using phosphoric acid of various concentrations as the electrolyte up to temperatures of 220° C, also using platinum for the electrode catalytic surface Fig 1 shows the polarization obtainable on simple platinum black electrodes using propane as the fuel Polarization is shown versus the reversible hydrogen electrode in the same electrolyte It can be seen from these results that current densities

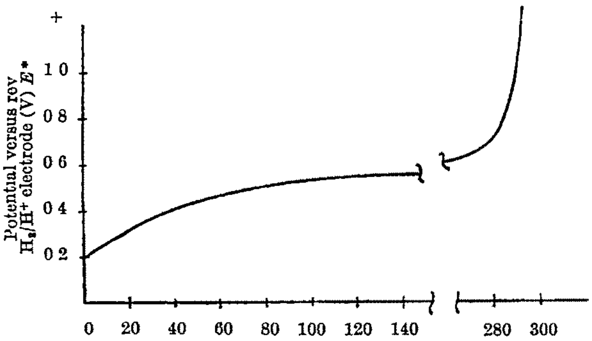

Fig 1 Polarization curve for propane/platinum black electrode 85 per cent phosphoric acid, 160° C

of the order 100–200 m amp/cm^2 are attainable under these conditions and at over-all cell voltages corresponding to thermal efficiencies between 20 and 35 per cent It has been observed with propane and higher hydrocarbons that the major product of oxidation is indeed carbon dioxide, but that methane also can be formed The formation of methane is favoured under open circuit conditions, which leads us to suspect that the reaction is purely a heterogeneous catalytic process involving cracking of the hydrocarbon to form "surface carbide complexes" and methane It is not likely that the formation of methane is an electrochemical process since at potentials of 200–300 mV positive to E^* (reversible hydrogen potential) the formation of methane would not be thermodynamically favoured

It would seem that it is a 'simple' cracking process which would require a finite value for the surface coverage with respect to hydrogen, that is, θ_H The rate of formation of methane will be a function of θ_H and it is well known that at potentials in the region of 200–300 mV E^* θ_H on platinum is very small

We feel that these results conclusively demonstrate the feasibility of a direct hydrocarbon/air fuel cell A considerable amount of work must now be directed towards demonstrating that such cells can be made to function in a practical fashion and can be built and operated economically

Photolysis of Sulphate Ion

The sulphate radical ion has been postulated as an intermediate in thermal reactions[1] and in the photolysis of peroxydisulphate ion in aqueous solution[2] Recently, it has been suggested as a possible intermediate in the flash photolysis of aqueous ferrous sulphate solutions[3]

We have determined the absorption spectrum of aqueous sulphate ion in neutral solution at 25° C using a Hilger Uvispek with nitrogen flushing as previously described[4] The spectrum corresponds to previously reported data[5,6] The value of the molar absorption coefficient of sulphate ion at 1849 Å was found to be 202 l mole^{-1} cm^{-1}

In view of the fact that many photolyses are carried out in systems containing sulphate ion, it was decided to investigate the possibility of direct photolysis of the ion by 1849 Å radiation

A de-aerated aqueous solution consisting of 1 0 × 10^{-1} M sodium sulphate and 1 0 × 10^{-1} M methanol was irradiated using a low-pressure mercury vapour discharge lamp, the apparatus and technique being similar to that described previously[7] The fractions of 1849 Å radiation absorbed by the components of this solution were $SO_4^{=}$ 0 905, CH_3OH 0 028 and H_2O 0 067 Conditions of complete absorption were realized in the photolysis, the results of which showed a yield of hydrogen of 1·62 × 10^{-5} mole l^{-1} min^{-1} The quantum yields for water and methanol[7] photolysis are 0 6 and 1 0 respectively at the wave-length used so that hydrogen yields arising by direct photolysis of these components can be calculated for the foregoing experiment They are 10 3 × 10^{-7} mole l^{-1} min^{-1} from water and 7·2 × 10^{-7} mole l^{-1} min^{-1} from methanol Thus 1 45 × 10^{-5} mole l^{-1} min^{-1} of hydrogen must arise from direct absorption by sulphate ion This result would indicate a value of 0 63 for the quantum yield for the direct photolysis of sulphate ion in the presence of 1 0 × 10^{-1} M methanol

We have observed that the quantum yield for sulphate photolysis varies with the methanol concentration This is due to several factors, one of which is a change in the absorption characteristics of the solutions as the methanol concentration increases Further work is being carried out together with a detailed investigation of the effect of methanol addition on the spectrum of sulphate ion

Although the intensity of absorption by sulphate ion is low compared with intensities associated with many electron transfer spectra it is possible that the initial absorption process may be represented by

$$SO_4^{=}\,H_2O \rightarrow (SO_4^{-}H_2O^{-})^{*} \rightarrow SO_4^{-} + H + OH^{-} \qquad (1)$$

followed by

$$SO_4^{-} + H_2O \rightarrow HSO_4^{-} + OH \qquad (2)$$

the net effect being the indirect photodissociation of water

Free radicals can be detected by including organic compounds in the system which act as scavengers by providing extractable hydrogen atoms The scavenger used in this work was methanol In the presence of methanol reaction (2) may be replaced by the energetically more favourable process

$$SO_4^{-} + CH_3OH \rightarrow CH_2OH + HSO_4^{-}$$

CH_2OH radicals can also arise by

$$H + CH_3OH \rightarrow CH_2OH + H_2$$
$$OH + CH_3OH \rightarrow CH_2OH + H_2O$$

subsequent reactions of the radical being

$$2\,CH_2OH \rightarrow (CH_2OH)_2$$
$$CH_2OH + OH \rightarrow H_2O + CH_2O$$
$$\cdot CH_2OH + SO_4^{-} \rightarrow HSO_4^{-} + CH_2O$$
$$CH_2OH + H \rightarrow H_2 + CH_2O$$

so that the expected products would be gaseous hydrogen, and in solution formaldehyde and ethylene glycol, the product balance being

$$\varphi_{H_2} = \varphi_{CH_2O} + \varphi_{(CH_2OH_2)_2}$$

Investigation of the solution products does reveal a balance between the gas yield and the yields of formaldehyde and ethylene glycol as suggested Formaldehyde was found to be 15 per cent of the gas yield and ethylene glycol 85 per cent, which are identical to those found in the water–methanol system[7] This suggests that the photolysis of sulphate ion may give radicals identical to those present in the direct photolysis of water

Donnan Equilibria in Polyelectrolyte Solutions

MEMBRANE equilibria, involving a macromolecule, impermeable through the membrane, and a permeable salt, were first investigated by Donnan[1]. He found that at equilibrium the salt was unevenly distributed between the two sides of the membrane, and he advanced a theory to explain the effect. Since then this effect has been intensively examined, first especially with proteins, later even with linear polyelectrolytes.

In recent years numerous theoretical[2–6] papers on the subject have appeared whereas much less attention has been given to the experimental side of the problem, and accurate data are, in general, lacking. In the work recorded here precision measurements on a linear polyelectrolyte and a non-electrolyte polymer are reported. It is shown that the classical Donnan theory alone does not explain the behaviour of linear polyelectrolytes and that in addition an 'excluded volume' effect is present. In this it is assumed that the permeable salt is partly excluded from the interior of the polyelectrolyte molecule. The excluded volume effect has also been considered by Strauss and Ander[7] in an investigation of polyphosphate solutions.

The polymers used in the present experiments were poly-methacrylic acid (PMA) and poly-oxy-ethylene (POE $(CH_2CH_2O)_n$). The permeable electrolytes were sodium hydroxide and sodium hydroxide in the presence of sodium chloride. The dialysis cell was essentially an enlarged block-type osmometer cell, made of polyethylene and with a membrane of 'Cellophane'. The equilibration of the solutions was carried out at 25° C for 24 h. This was well in excess of the actual time necessary for the equilibrium to be established.

The concentration of sodium hydroxide was determined by titration with hydrochloric acid. In solutions containing PMA a sharp equivalence point was found near *p*H 10, where the excess sodium hydroxide was neutralized, but the PMA was still in the form of its sodium salt. This point could be accurately determined with thymolphthalein as indicator. In the actual experiments 25 ml. of the equilibrated solutions were transferred with a pipette to glass stoppered flasks and weighed. Most of the alkali in the solutions was then neutralized by adding to each flask 25 ml. of a standard hydrochloric acid solution with a precision pipette. The final neutralization of the alkali was carried out by titrating with a 0.05 M hydrochloric acid solution using a microburette and thymolphthalein as indicator. By this method the concentrations of sodium hydroxide in the two solutions could be determined with a relative accuracy of about 0.01 per cent. The concentrations were expressed in weight units with the following designations

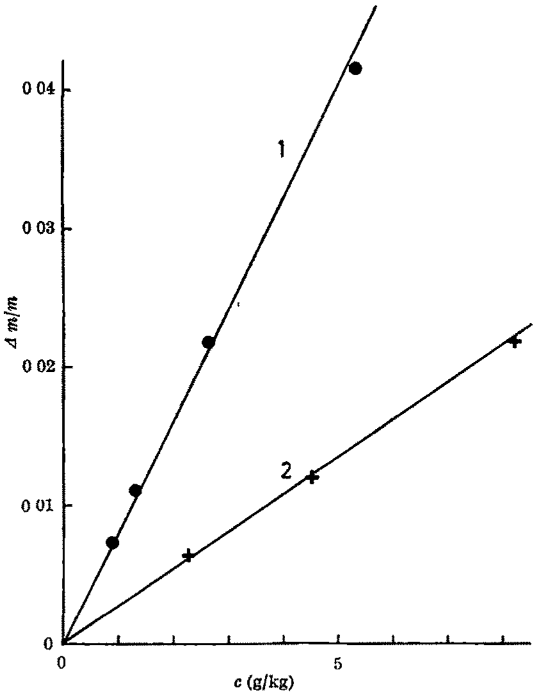

Fig. 1. Measurements at constant sodium hydroxide concentration. Curve 1 for PMA with m = 0.25 M/kg, curve 2 for POE with m = 0.5 M/kg

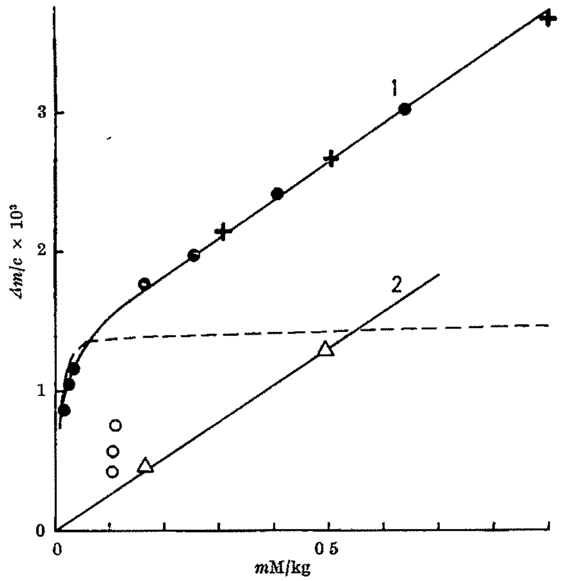

Fig. 2. Measurements at constant polymer concentration. Curve 1 for PMA with c = 5.2 g/kg, curve 2 for POE with c = 4.5 g/kg. Open circles represent Δm for sodium hydroxide in PMA solutions in the presence of sodium chloride, from top to bottom m_{NaCl} = 0.20, 0.40 and 0.80 M/kg. The crosses on curve 1 represent the corresponding Δm values referring to the total permeable electrolyte concentration. The dotted curve represents equation (1) with c = 5 g/kg and with ε = 0.25

permeable electrolyte	m moles per kg of solution
polymer	c g per kg of solution

The results are shown in Figs. 1 and 2. They are expressed in terms of $\Delta m = m - m_1$, where m_1 and m are the m-values for the solution containing the polymer and for the solvent respectively. Fig. 1 shows some results from measurements at constant sodium hydroxide concentration and varying polymer concentrations. We see that with both polymers Δm is very nearly proportional to the polymer concentration. In Fig. 2 the polymer concentration is kept constant and the concentration of the permeable electrolyte varied. With PMA some measurements were carried out with sodium hydroxide in the presence of varying amounts of sodium chloride. We see that Δm for sodium hydroxide is depressed by the presence of sodium chloride. However, if we assume that chloride is displaced to the same extent as sodium hydroxide, and we calculate Δm for the total amount of permeable electrolyte, we find that the points fall on the curve for pure sodium hydroxide. This indicates that both electrolytes behave similarly in this connexion.

The classical Donnan theory gives for Δm the following formula

$$\Delta m = \frac{\dfrac{c\varepsilon}{M}}{1 + \sqrt{1 + \dfrac{c\varepsilon}{Mm_1}}} \qquad (1)$$

where ε is the degree of dissociation of the polyelectrolyte and M its equivalent weight. In Fig. 2, together with the experimental results, a curve representing equation (1) for PMA with c = 5 g/kg and with ε = 0.25 is shown. We see that equation (1) cannot be made to fit the experimental results.

For the excluded volume effect we have in the first approximation

$$\Delta m = \alpha m c \qquad (2)$$

where α determines the excluded volume (in the present units it equals the mass of solution in kg/g polymer, from which the permeable electrolyte is excluded)

Comparing equation (2) with the experimental results, we see that with POE the agreement is excellent From both diagrams we obtain $\alpha = 0\ 0027$ kg/g As the polymer mass itself is included in α this means that for each gram of the polymer there are 1 7 g of (solvating) water from which sodium hydroxide is excluded With PMA the situation is more complicated A comparison of the experimental results in Fig 2 with the predictions of the Donnan theory and the excluded volume effect reveals that the experimental curve may be obtained by a superposition of these two effects It is interesting to note that the excluded volume effect for PMA happens to be of the same magnitude as for POE

I may conclude by stating that the experiments recorded here indicate that in linear polyelectrolyte solutions two effects are present, namely, the classical Donnan effect and the excluded volume effect The latter occurs even with non-electrolyte polymers These matters are treated further in a paper to be published in *Acta Chemica Scandinavica*

Partial Differentiation, with Special Reference to Thermodynamics

From time immemorial savants and scholars have taken liberties with well-known words and phrases and by 'new definitions' have imparted highly specialized meanings to familiar expressions While in some cases such actions can be justified on the grounds of greater clarity of meaning and greater precision of definition, as a general practice the imparting of specialized meanings to well-known words and phrases tends to obscure any language, even the language of mathematics, particularly when the specialized meanings involve largely meaningless 'new definitions'

In a recent communication, Elliott[1] has suggested a new definition for the partial derivatives occurring in thermodynamics The approach is based on the form

$$dz = a dx_1 + b dx_2 + c dx_3 \qquad (1)$$

and it is stated that a, b, and c in the limit of small displacement dx_1, dx_2, dx_3 are to be identified with the new partial derivatives and indicated as $\frac{\partial z}{\partial x_1}$, etc

No restrictions are imposed on the manner in which the limit is to be taken and, in our opinion, the failure to do this renders the definition meaningless

As an illustration of our criticism let us introduce the symbols Z_1, Z_2, Z_3 to represent the 'old' derivatives of z, that is, Z_1 is the rate of change of z with respect to x_1 keeping x_2 and x_3 constant Then to a first order of small quantities

$$dz = Z_1 dx_1 + Z_2 dx_2 + Z_3 dx_3 \qquad (2)$$

Evidently by keeping x_2 and x_3 constant we can deduce from (1) and (2) that

$$a = \frac{\partial z}{\partial x_1} = Z_1$$

On the other hand, for $dx_1 = dx_2$ and x_3 kept constant

$$\frac{\partial z}{\partial x_1} = Z_1 + Z_2$$

and so on The symbol $\frac{\partial z}{\partial x_1}$ can have an infinity of values depending on how we approach the limit

Dr Elliott implies that the freedom from restrictions in taking the limit is one of the merits of his definition We believe it can only lead to confusion in a field where precise definitions are essential

---

[1] Elliott, G A, *Nature*, **198**, 1191 (1963).

The preceding communication shows that if the partial differential indicated by $\partial z/\partial x_1$ is defined as the limiting value of the rate of change of z with respect to x_1, and if we include changes due to the variation of x_2 (which is dependent on x_1) then the result obtained depends on the relation between x_1 and x_2 and in particular if $dx_1 = dx_2$ the expression is

$$\partial z/\partial x_1 = Z_1 + Z_2$$

This 'definition' is therefore quite useless, and on this point there is no dispute

On the other hand, if we define the partial differential in the way proposed in my previous communication we always obtain the result $\partial z/\partial x_1 = a$ and no other answer is possible The symbol $\partial z/\partial x_1$ is to be regarded simply as a rather clumsy but time-honoured method of indicating the coefficient a or rather its limiting value when the neglect of differentials of higher order than the first in forming equation (1) above is strictly justified The new definition is strictly independent of any relations between the variables

BIOCHEMISTRY

Enzymatic Evidence for the Configuration of *d*-Isocitric Acid

The configuration of the α-carbon atom of the *d*-isocitric acid of the Krebs tricarboxylic acid cycle was designated L_S on the basis of an application of the Levene displacement rule[1], but subsequent chemical[2-4] and X-ray[5] studies indicated the D_S configuration Other investigations have shown that the α- and β-asymmetric centres of *d*-isocitric acid possess opposite configurations[6,7]. Although *d*-isocitric acid may be distinguished by the action of isocitric dehydrogenase from the three isomeric isocitric acids, none of the isomers of α-aminotricarballylic acid, the α-amino analogue of isocitric acid, has thus far been found to be attacked by enzymes Greenstein and Winitz[1], who prepared both DL-α-aminotricarballylic and DL-allo-α-aminotricarballylic acids, were unable to find an enzyme capable of resolving these and therefore resorted to the use of brucine They thus obtained the corresponding four optical isomers, which they converted to the respective isocitric acids by treatment with HNO_2

Application of the Clough–Lutz–Jirgensons rule permitted assignment of configuration to the D- and L-isomers of *allo*-α-aminotricarballylic acid, but assignment of the configurations of the isomers of α-aminotricarballylic acid was not possible by this procedure. Application of the Levene displacement rule[8] to the derived isocitric acid isomers indicated the L_S configuration for *d*-isocitric acid and therefore also for *l*-α-aminotricarballylic acid, the amino-acid isomer from which it was derived.

The enzyme recently obtained in this laboratory[9] from mammalian kidney that catalyses the optically specific cyclization of D-glutamic acid to D-pyrrolidone carboxylic acid also catalyses the cyclization of the D-isomers of α-methylglutamic acid, γ-methylglutamic acid, and one-half of several racemic glutamic acid derivatives including α-aminotricarballylic and *allo*-α-aminotricarballylic acids, which may be considered as glutamic acids possessing β-carboxyl groups. DL-*Allo*-α-aminotricarballylic acid on treatment with HNO_2 was previously shown to give isocitric acid that was unreactive with isocitric dehydrogenase[10].

DL-α-aminotricarballylic acid was prepared by acid hydrolysis of the corresponding DL-pyrrolidone-α,β-dicarboxylic acid (kindly provided by Dr. Milton Winitz). Incubation of DL-α-aminotricarballylic acid with the mouse kidney enzyme[9] led to disappearance of approximately 50 per cent of the ninhydrin-reactive material; on addition of more enzyme no further amino-acid disappeared. The reaction mixture was deproteinized and placed on a column of 'Dowex 50' in the H^+ form. The water effluent containing the enzymatically formed D-pyrrolidone-α,β-dicarboxylic acid was evaporated to dryness and hydrolysed with 2 N hydrochloric acid for 2 h at 100°. The L-α-aminotricarballylic acid was eluted from the column with 2 N ammonium. The D- and L-α-aminotricarballylic acids thus obtained were converted to the corresponding isocitric acid isomers by reaction with HNO_2. Assay with the isocitric dehydrogenase–NADP system indicated that the isocitric acid obtained from the amino-acid isomer that had cyclized was enzymatically active and accounted for 80 per cent of the *d*-isocitrate obtained from a control sample of DL-amino-acid, which was not treated with the cyclizing enzyme. That the amount of *d*-isocitrate recovered was less than theoretical may be ascribed to incomplete conversion of amino-acid to hydroxy acid under the conditions adopted, and to losses during elution and other manipulations. The isocitrate obtained from the α-aminotricarballylic acid isomer that was eluted from the column with ammonium contained only 7 per cent as much *d*-isocitrate as found in the isocitrate preparation obtained from the cyclized product; this finding is consistent with the observation that cyclization reaches equilibrium at about 95 per cent of completion[9]. These enzymatic studies are therefore in agreement with the chemical and X-ray findings and provide additional evidence that the isocitric acid of the Krebs cycle has the D_S-configuration and may, in accordance with the nomenclature proposed by Vickery[11], be designated *threo*-D_S-isocitric acid.

Distribution of Carbon-14 in Polysaccharide after Photosynthesis in Carbon Dioxide labelled with Carbon-14 by *Anacystis nidulans*

THE reductive pentose phosphate cycle[1] has been proposed as the means of formation of hexose during photosynthesis. The enzyme fructose-1,6-diphosphate aldolase is an integral part of the cycle. It was therefore unexpected that Richter[2] could not detect aldolase in extracts of the photoautotrophic blue-green alga, *Anacystis nidulans*. This observation was confirmed and extended by Fewson, Al-Hafidh and Gibbs[3] to include other members of the Cyanophyceae. Recently, Kandler[4] reported that the distribution of carbon-14 in the products formed during photosynthesis in $^{14}CO_2$ by *A. nidulans* was similar to those obtained with *Chlorella*, an alga which contains aldolase. It therefore became of interest to examine the distribution pattern of carbon-14 in the polysaccharide formed during photosynthesis in $^{14}CO_2$ by the two types of algae.

A. nidulans and *C. pyrenoidosa* were grown as described in a previous publication[3]. After collection, the cells were suspended at a concentration of 2 g of wet weight per 100 ml of 0.025 M potassium phosphate, *p*H 7.0. Twenty-five ml of cell suspension were placed in a glass 'lollipop', which was illuminated from each side by two incandescent spotlights each of which gave 4,000 ft.-candles at the surface of the 'lollipop'. After 10 min of illumination with air being continuously bubbled through the suspension, $NaH^{14}CO_3$ (348 μc./m.mole) was introduced. When the required time-period had elapsed (Table 1), the algal suspension was dropped into 250 ml of boiling 90 per cent (v/v) ethanol. The suspension was centrifuged and the solid material was extracted with absolute ethanol, 20 per cent (v/v) ethanol, and finally with water. The residue remaining was heated with 15 ml of 1 N hydrochloric acid for 1.5 h in a 100° water bath. The neutralized solution was deionized by passing it through 'Dowex 50 *W* (H^+)' and then through 'Amberlite *CG*-4*B*(OH^-)'. The effluent was evaporated under vacuum at 30° and then streaked on Whatman No. 3 MM paper along with unlabelled glucose and galactose. The chromatogram was developed with a mixture of *n*-butanol, 95 per cent ethanol and

30	26	21	73	100 (27)	11	19

Value in parenthesis is the specific activity of C-4 expressed in mμc /mg carbon

water (52 32 16) Only one band of radioactivity was found This band corresponded to glucose and was identified by cochromatography with authentic sugar and by its colour reaction with aniline hydrogen phthalate Each glucose sample together with 600 μmoles of carrier glucose was degraded by the *Leuconostoc mesenteroides* method[5] Table 1 shows the results The asymmetric pattern of distribution of carbon-14 in the glucose of the polysaccharide isolated from both algae is almost identical at any given time

These results and those of Kandler[4] suggest the following (1) aldolase is present in *Anacystis* and *Chlorella* and the reductive pentose phosphate cycle functions in both organisms, but the enzyme is not detected in extracts of *Anacystis* for various reasons[3], (2) aldolase is not involved with the conversion of carbon dioxide to carbohydrate during photosynthesis, (3) different mechanisms of photosynthetic assimilation of carbon dioxide operate in the two algae but both mechanisms give rise to the same distribution of carbon-14 pattern

Natural Occurring Variations in Rat Liver DNA Content

THE content of deoxyribonucleic acids (DNA) in non-dividing somatic cells is believed to be constant[1,2] For this reason the nucleic acid content is a reference standard in several biochemical investigations On the other hand, there are few data which lead to the conclusion that DNA content is not very constant[3] and one has to assume that DNA occurs also in a metabolic form[4]

In an investigation of the influence of sex and season on the diurnal rhythm of rat liver content, nucleic acids were biochemically and histologically determined This investigation was carried out with untreated animals of an inbred Wistar strain of both sexes kept under constant conditions (temperature, humidity, free access to food and water) The determination of nucleic acids after fractionated extraction and ultra-violet spectrography and the Dische test has shown that the DNA-content varies very little during day-time in the spring The content is about 18 γ/100 mg liver wet weight In the night there is a strong increase of the DNA with a maximum of 73 γ/100 mg There are no differences between sexes by the time the peak is reached Assays carried out in winter (January 1963) show quite different patterns of amount of DNA when estimated every 2 h for 24 h Here I found two marked peaks (12 h and 18 h) during the day, while at night the content is low and without very strong variations Sexual differences are marked in winter by a time difference of 2 h reaching the maximum peaks The proportions of the values are the same when DNA-content is calculated for the dry weight of total protein content

This leads to the conclusion that DNA changes not only in a diurnal rhythm pattern, but also that this pattern is influenced by the sex and season

Disassociation of Heart Cells by Collagenase

THE disassociation of cells from various parent tissues by digestion with trypsin has been often applied by workers on tissue cultures[1-3] There are, however, several defects in the trypsinization method when the goal is use of the cells for physiological investigations We have examined various possible methods for avoiding these difficulties and have found that the substitution of collagenase for trypsin satisfied most of our requirements

The criteria for a suitable disassociating enzyme were (*a*) cell damage must be minimized, (*b*) cell yield should be high; (*c*) the mucus-like strands which appear during trypsinization should be absent, (*d*) the ionic environment during disassociation should be normal It was observed that, using trypsin, the proportion of injured or dead cells as indicated by the nigrosin uptake method[4] was fairly high, particularly when old embryonic hearts (11–16 days) were used It was also noted that quite large amounts of non-cellular material and ropes of mucus-like substance were always present following tryptic digestion Furthermore, many workers[2] when using trypsin have found it desirable to reduce the concentrations of divalent cations in the digestion medium In the work recorded here it was felt that the physiologically important factors to be studied (ion transport, transmembrane potentials, etc) might be seriously, possibly irreversibly, damaged by exposure to such an abnormal environment

The mucoid material in trypsinized suspensions suggested that collagen was present, accordingly, collagenase

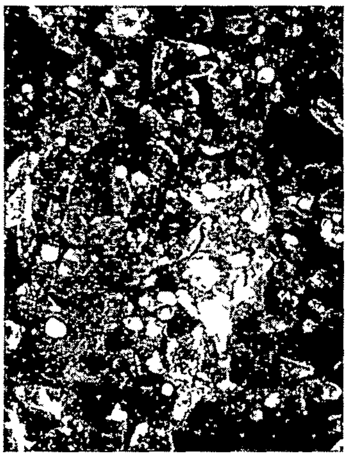

Fig 1 Collagenase 24 h culture (× *c* 245)

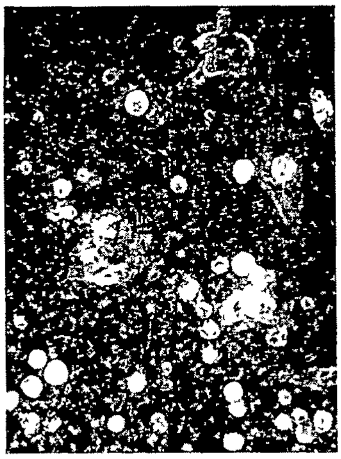

Fig 2 Trypsin 24-h culture (× *c* 245) Note large amount of non-cellular material, still rounded cells (many characteristically flattened cells were present elsewhere in culture, see Fig 4)

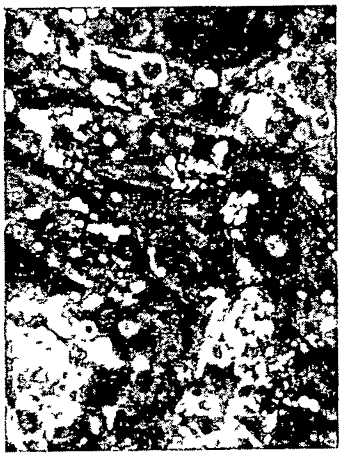

Fig 3 Collagenase 24-h culture (× *c* 700)

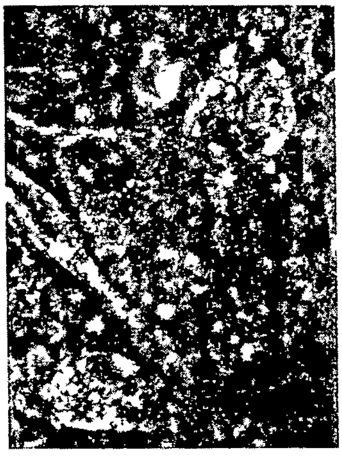

Fig 4 Trypsin 24-h culture (× *c* 700) Note that collagenase and trypsin yield essentially the same cytological characters but that the cell density is somewhat greater per field than with trypsin and there is less debris present

(partially purified collagenase, Worthington Biochemical Corp , Freehold, New Jersey) was tested alone and in mixtures containing trypsin or elastase or both Collagenase alone was as effective as trypsin, elastase was a very poor disassociating agent

The results of collagenase disassociation were (1) No mucoid strands were present (2) As measured with an

Table 1 COMPARISON OF CELL SIZE DISTRIBUTIONS

Trypsin distribution curve		Collagenase distribution curve	
Size plateau (μ^3)	Cell No /0 5 ml	Size plateau (μ^3)	Cell No /0 5 ml
15 3–16 9	990	12 25–13 8	2,121
	981		2,045
18 4–19 9	840	16 9–18 4	1,376
	839		1,372
24 5–26	525	24 5–26	755
	527		769
30 6–35 2	641	29 1–35 2	1,553
	688		1,595

For each digest, eleven 6 5–7-day-old embryos were dissected and the scissors-minced hearts were incubated in the enzyme solutions Trypsin was the '1 250' commercial (Microbiological Associates) preparation in normal saline Trypsin digestion period, 45 min Collagenase, 5 mg/ml in Gey's solution, digestion period, 60 min In each case 0 1 ml calf serum was added per ml enzyme solution and the hearts were added to 2 0 ml of the mixture Size distribution and cell counts were made on freshly prepared suspensions from the digests after washing and re-suspending in avian Ringer to give a 1 500 dilution Aperture, 70μ, instrument, Coulter counter model *B*

electronic counting and sizing apparatus (Coulter counter) (Table 1), the subjective appearance of fewer broken cells and more complete disassociation with collagenase were confirmed (3) Excellent cell separation and viability, as demonstrated by culture of the disassociated cells (Figs 1 and 3), were obtained using collagenase in a normal saline containing full complements of calcium and magnesium Using trypsin in calcium, magnesium-free media, suspensions were decidedly inferior (Figs 2 and 4) (4) A fairly high proportion of pulsating cells was present shortly after disassociation when collagenase was used Trypsinization yielded virtually no pulsating cells (5) The initial appearance of the cells in the two cases was quite different With collagenase, about 30 per cent of the cells retained an elongated, flattened shape, while tryptic digests always contained many more rounded cells (6) The speed of initial attachment to the glass of culture dishes and subsequent flattening and stretching were much greater when collagenase was used

In general, it appears that, at least for cells from muscular elements, collagenase may be considered superior to trypsin as a disassociating agent

The completeness of disassociation with collagenase suggested that some form of collagen was a major component of the inter-cellular binding material

A Simple Technique for the Isolation of $\beta_1C(\beta_1 A)$ Globulin

SERUM submitted to immuno-electrophoresis shows 4 distinct lines in the β_1-region The best known of these precipitation lines is $\beta_1 S$, that corresponding to siderophilin , this line has been identified by use of labelled iron $\beta_1 B$ is the line corresponding to a protein, with combining power for cytochrome and similar compounds , it was first isolated by Biserte, *et al* [1] Different names have been proposed for it, such as chromophilin, hæmopexin and β-haptoglobin The two remaining lines $\beta_1 A$ and $\beta_1 C$ show a somewhat complex behaviour Indeed, fresh serum will give the line corresponding to $\beta_1 C$ and aged serum the $\beta_1 A$ line However, a transient aspect is very common, showing a double or even triple curved line[2]

Muller-Eberhard *et al* have isolated both $\beta_1 C$ and $\beta_1 A$-globulin[3] and they have shown that the latter protein is a derivative formed from $\beta_1 C$-globulin by an ageing process This protein is the slowest of the 4

β_1-globulins The sedimentation rate is 9 5 S whereas that of β_1A, the most rapid globulin of this group, is only 7 S Muller-Eberhard, *et al*, also supplied evidence that β_1C-globulin is related to the complement system and more especially with $C'3$ (ref 4) β_1A shows no activity The technique used by Muller-Eberhard *et al* for the isolation of both these proteins is rather complex as is another procedure proposed recently by Schultze *et al*[5] The examination of the mechanism of the complement system would be greatly facilitated if workers in this field could easily dispose of the isolated components

The technique developed in our laboratory is simple and gives β_1C-globulin in good yield and purity without special equipment, not more than 24 h, including time for dialysis, being necessary to obtain this result

Plasma (6 per cent protein, pH 7 5–8) is adsorbed by bentonite (2–2 5 per cent) during 15 min at room temperature Bentonite adsorbs mainly fibrinogen, lipoprotein and certain clotting components[6,7]

This mixture is centrifuged, the precipitate discarded, and the pH of the supernatant immediately adjusted to pH 6 3 An aqueous solution of rivanol (0 5 per cent) is now added (50 ml for 100 ml of plasma) The mixture is stirred for 30 min, then left an additional hour at room temperature

The mixture is then centrifuged (30 min) The precipitate is quickly washed with ice-water or 0 05 per cent rivanol solution and centrifuged again It is then extracted by 1/5 of the initial plasma volume of 3 per cent sodium chloride The crude saline extract is again adsorbed by bentonite (1 5–2 per cent) during 15 min (pH should be maintained at 8, bentonite adsorbs anions and the pH usually rises to 9 or more)

The supernatant obtained after centrifugation is dialysed against acetate buffer (0 01 M) at pH 5 3 at 4° The precipitate is centrifuged, washed with buffer and dissolved in saline at neutral pH The solution contains mainly β_1C-globulin, which may be accompanied by some lipids and lipoprotein Acidification at pH 6 3, adsorption on silica or treatment by dextran-sulphate (or similar products) may be used for the elimination of these lipidic contaminants This purification step might be unnecessary and the redissolved euglobulin precipitate can be used directly for certain purposes

ACD plasma as well as serum can be used as a starting material From fresh and frozen plasma we almost always obtained β_1C-globulin This protein migrates as a β_1-globulin on paper and agar, its position on starch gel, as revealed by a microtechnique[8], is approximately in the middle between α_2-macroglobulin and siderophilin When β_1C is left in the ice-box for some time, it will slowly undergo transformation into β_1A-globulin Two lines will be seen after starch gel electrophoresis and the preparation submitted to immunoelectrophoresis will reveal the characteristic double or triple curved lines (Fig 2) After several weeks β_1C has completely disappeared, leaving β_1A and some break-down products, as revealed by electrophoresis on starch gel and immunoelectrophoresis The isolated β_1C–β_1A-globulin is also revealed by antiserum obtained from horse 1299 (Institut Pasteur) (We thank Dr J M Fine for this analysis) Hence, this antiserum contains only one single antibody against β_1-globulins, namely, anti-β_1A, this result gives a further proof for the identity of our protein with β_1C- β_1A-globulin

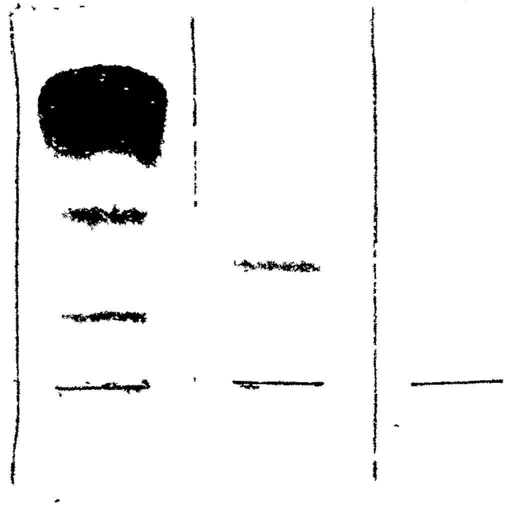

Fig 1 Starch-gel electrophoresis (microtechnique) (*a*) Normal serum (*b*) β_1C freshly prepared, (*c*) same preparation after storage at + 4° undergoing transformation to β_1A globulin

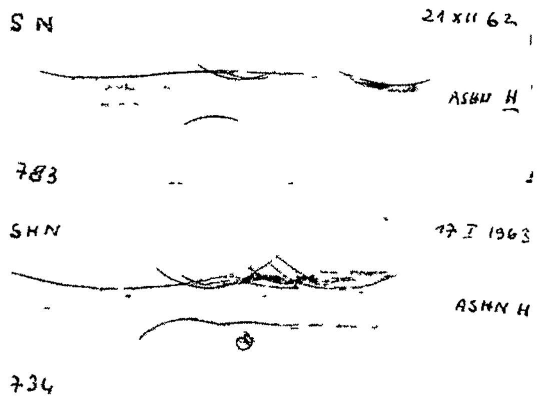

Fig 2 Immunoelectrophoresis of β_1C–β_1A-globulin Above, β_1C-globulin (0 8 per cent) freshly isolated, below, same preparation after storage at + 4° during 4 weeks showing partial transformation to β_1A

Sodium – Potassium-activated Adenosine Triphosphatase in Schizophrenic Erythrocytes

SINCE Skou's[1,2] description of a sodium–potassium-activated adenosine triphosphatase in crab nerve, many reports have indicated that this enzyme has properties virtually identical to those exhibited by the Na^+ extrusion mechanism in many tissues[3–8] The intracellular concentrations of Na^+ and K^+ ions are of importance in regulating cell membrane excitability in nerve, muscle[9], secretory cells, etc It is also known[10] that the amount of this enzyme in sheep erythrocyte membranes correlates with the intracellular concentration ratio of K^+/Na^+, which is in turn regulated by a gene[11]

The ætiology of schizophrenia remains unknown Kallmann's[12] statistics as well as Slater's[13,14] suggest that the disease is predominantly a manifestation of an autosomal recessive gene Because of this strong genetic character of schizophrenia, it would seem likely that some

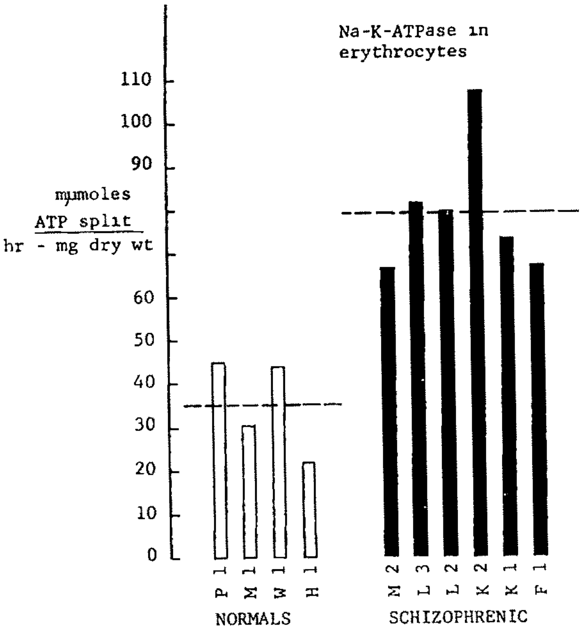

Fig 1

protein abnormality might be found On the assumption that schizophrenia may be a 'disease of cell excitability' we decided to investigate a membranal enzyme intimately associated with cell excitability, namely, sodium–potassium–ATPase

Blood (20 ml) was drawn from 4 normal volunteers and 6 sub-acute paranoid schizophrenic patients The erythrocyte membranes (ghosts) were prepared according to the method of Bonting and Caravaggio[6] with minor modifications The *tris*–EDTA washes were alternated with 0 3 per cent sodium chloride instead of with 0 986 g/l sodium chloride At the end of the procedure the ghosts were again washed twice in *tris*–EDTA For sodium–potassium–ATPase assay 0 1-ml aliquots of the final resuspended sediment were added to 0 1 ml of medium *A* and medium *D* as outlined by Bonting *et al* [15] After correction for the blanks the difference in activity between media *A* and *D* corresponded to sodium–potassium–ATPase Triplicate enzyme determinations were within 3 per cent Duplicate dry weights of the ghost suspensions were within 5 per cent The results are shown in Fig 1

The mean sodium–potassium–ATPase for the 4 normals is 35·2 ± 11 6 (standard deviation) mμmoles ATP split/h/mg dry weight The value for the patients is 79 1 ± 14 On Student's *t* test these mean values are significantly different with *P* less than 0 001 Subtracting the sodium–potassium–ATPase from the total ATPase gives the 'residual ATPase' this is 180 ± 10 for the normals and 246 ± 90 for the patients The difference between these two means is not significant ($P = 0\ 2$) Only 2 patients had received any tranquillizer in the week preceding *M*2 and *K*1 had received 200 mg hora somni and 150 mg 'Thorazine' daily, respectively The patient with the highest value of sodium–potassium–ATPase, *K*2, had been off all medication for 4 weeks

The normal sodium–potassium–ATPase of 35 units agrees fairly well with that of Post *et al* [3], who found an average of 20 units using 4 ghost preparations It is known that enzyme-levels vary with the age of the erythrocyte, young red cell fractions, containing 12 times the number of reticulocytes than old cell fractions, have about 30 per cent greater enzyme activity[16] These schizophrenic patients, however, have approximately normal reticulocyte counts It will be necessary to examine many more bloods of patients not on tranquillizers and it might be preferable to examine the enzyme level in cerebro-cortical biopsy or autopsy material

We are indebted to Dr Herman C Denber, director of research at Manhattan State Hospital, New York, for his co-operation

Compounds interfering in the Diphenylamine Test for Deoxyribonucleic Acid

THE use of DNA (deoxyribonucleic acid) as a reference standard in biochemical investigations[1], which is now well established, rests on the observed constancy of DNA content in each somatic cell in a species With certain exceptions, the number of cells in a sample may be related to the amount of DNA[2]

One procedure for determination of DNA, namely, the use of the diphenylamine reagent[3], has been reviewed[4], and the variables examined Considerable interference has been noted in some cases[5], but in general the reaction provides a reliable method of assay

Briefly, the method involves extracting the tissue with hot trichloroacetic acid, and then boiling the extract with the diphenylamine reagent[3] Within 5 min there is rapid development of a purple-blue coloration, which increases in intensity somewhat on longer heating The solution shows a characteristic absorption band in the ultra-violet region at 5800–6000 Å

When interfering substances are present, as shown by an alteration in the colour observed, the utility of the reaction may be preserved by suitable modifications[4] If the correct colour is produced it is generally assumed that no interference is occurring However, we have observed, on occasion, a normal colour with material, which on closer examination gave no maximum in the region expected Instead a peak occurred at 5000–5500 Å, often accompanied by a second peak at 6500–6800 Å, sometimes having a shoulder at 5700–6000 Å Reference to the literature[6] showed that the cause of this type of interference was suggested to be mucopolysaccharides

With pure DNA it is usually considered that boiling for 15 min is required for full colour development[7] although 10 min was suggested to be sufficient by other authors[8] When small amounts of interfering material are present considerable inaccuracies appear with 10–15 min heating and to obtain reliable estimates it is best, I find, to restrict heating to 5 min, since the colour from the interfering material develops more slowly than the colour from the DNA To obtain reliable figures for DNA when large amounts of interfering substances are present I find it most useful to plot absorbance against time of heating, in the region 5800–6000 Å

Since the pure DNA/diphenylamine-reagent colour shows only weak absorption in the region of 5400 Å and of 6600 Å, a similar plot at these wave-lengths gives a good indication of the rate of development of interfering colour Plots in these two regions usually give smooth curves

In the 5800–6000 Å region, however, such plots produce curves with a sharp break at about 5 min Back-extrapolation of these curves from 30 min through 10 min to zero time gives a good measure of DNA concentrations, since there is little increase in intensity due to DNA after this time

Fig 1 shows the variation in the absorption spectrum with time for a typical test Fig 2 shows the plot of absorbance against time at different wave-lengths to illustrate the foregoing points

Alternative methods of assay[9] should be used as a further check, if possible, although considerable divergences of view exist as to the interpretation of some of these methods[10]

To gain further evidence concerning the nature of the materials interfering in the Dische test, a number of substances were subjected to the test Table 1 lists those compounds which gave similar colours under the test conditions, together with the absorption peaks associated with the colour

Although in certain cases a careful comparison of the colours produced, when a compound and DNA were separately tested, distinguished the compound from DNA, if tested in admixture the resultant colour was visually indistinguishable from the colour produced by DNA alone

In each case, however, the rate of development of interfering colour was slower than the initial increase in intensity at 5900 Å The addition of known amounts of DNA to test solutions of these compounds showed that reasonable accuracy was obtained by the extrapolation suggested, and that the measurement of intensity after 5 min heating, although less accurate, gave moderately satisfactory results under controlled conditions

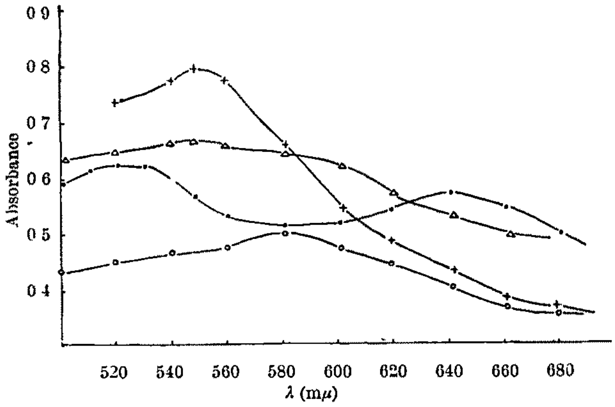

Fig 1 Spectra obtained from interfering substances compared with those from lactating mammary gland +, 5-Methyl furan heated 30 min, ●, fructose heated 30 min, O, mammary gland, heated 6 min (*B*), Δ, mammary gland, heated 30 min (*C*)

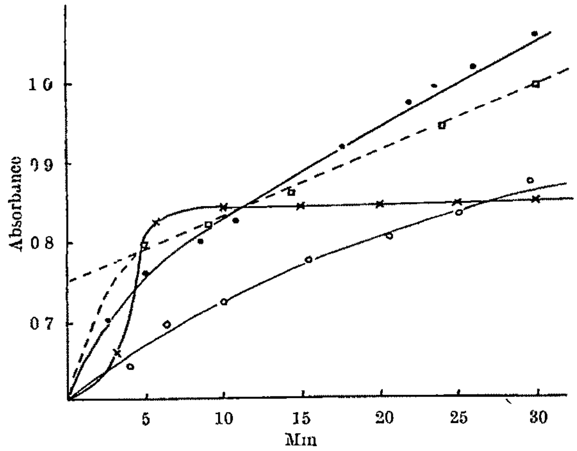

Fig 2 Change of spectra with time of heating □, Mammary gland at 590 mμ, O, mammary gland at 660 mμ, ●, mammary gland at 540 mμ, ×, DNA at 590 mμ

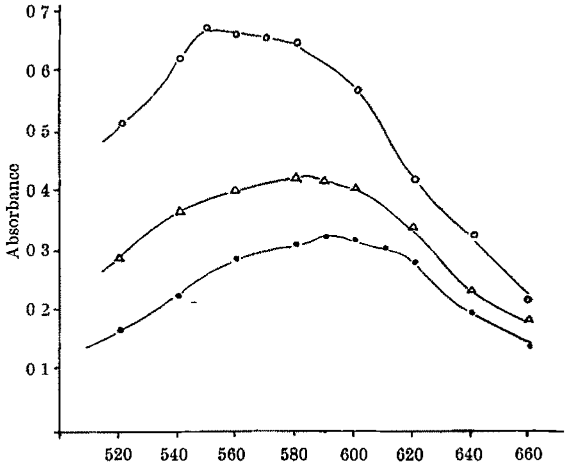

Fig 3 Absorption spectra from DNA and from DNA – 5-methyl furan mixture Compare Fig 1, *B* and *C* O, Mixture heated 30 min, Δ, mixture heated 10 min, ●, DNA alone

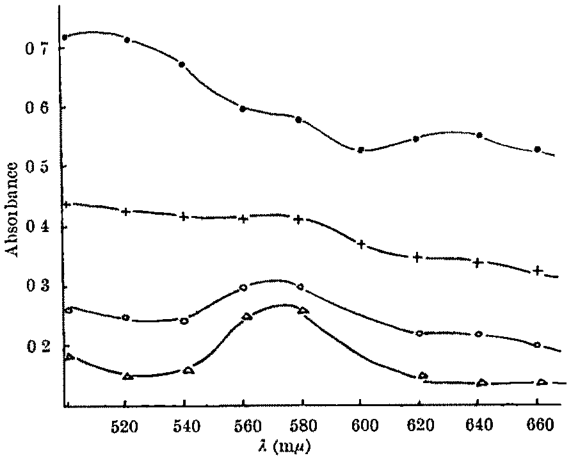

Fig 4 Spectra from DNA – 5-hydroxymethyl furfuraldehyde mixture (aldehyde obtained from sucrose treated with trichloroacetic acid) ●, Mixture heated 30 min, +, mixture heated 10 min, O, mixture heated 5 min, Δ, DNA alone Compare Fig 1, *B* and *C*

Some of the compounds listed (Nos 1–5, 16, Table 1) are known to occur often in tissues[11], while others (Nos. 6–15, Table 1) are either uncommon or have not been noted to occur

However, since treatment with hot trichloroacetic acid is a preliminary to the test, it should be noted that hot acids convert the methylpentoses, rhamnose and fucose[12], to 5-methylfurfuraldehyde (compound 12, Table 1) and convert ketohexoses[13] and sucrose[13] to 5-hydroxymethyl furfuraldehyde (compound 7, Table 1)

Table 1

	Compound	Absorption maxima (Å)
1	Fructose	5200 and 6300
2	Sorbose	
3	Fructose 1-phosphate	
4	Fructose 1,6-diphosphate	
5	Sucrose	
6	Levulinaldehyde	5550
7	5-Hydroxymethyl furfuraldehyde	5200 and 6300
8	2-Deoxy-glucose	5100
9	2-Deoxy-galactose	
10	Glucal	
11	Galactal	
12	5-Methyl furfuraldehyde	5500
13	2-Methyl furan	5850
14	5-Methyl furfuryl alcohol	
15	4,5-Dihydroxy valeraldehyde	5550
16	Sialic acids (various samples)	Deep violet-blue colour, maximum not determined

In certain plant tissues, where interference has occurred, high concentrations of methyl-pentoses are probably responsible in some cases, and high concentrations of sucrose and/or fructose in some other cases In animal tissues interference of this type has so far been encountered in normal serum, in lactating mammary gland, and in certain disease conditions, for example, some types of rheumatoid arthritis, among other cases

I suggest that the nonulosaminic (sialic) acids are a common cause of interference Not only are these acids often associated with methyl-pentoses (6-deoxy-hexoses) (for example, fucose), which may give an interfering colour by conversion to methyl-furfuraldehyde, but in addition they themselves give a blue-violet coloration when treated with the Dische reagent In the past few years these acids have been found to occur in a large number of tissues (Table 2) including those found to give trouble in this test

Table 2 OCCURRENCE OF NONULOSAMINIC (SIALIC) ACIDS, AND THE CARBOHYDRATES FOUND IN ASSOCIATION (REF 18)

Origin	Associated sugars	Ref
Mucin of bovine submaxillary gland	*N*-Acetyl-glucosamine, glucose, glucosamine, fucose, mannose	14
Brain (especially gangliosides), serum*, cerebrospinal fluid, erythrocytes, saliva, vitreous humour, urine, bronchial and epithelial tissue, liver*, mammary gland (lactating)*	Mannose, fucose, galactose, galactosamine, glucosamine	15
Milk (human)*, colostrum (bovine)*	Lactose, galactose, glucose, fucose, *N*-acetyl-galactosamine	17
E coli		16

Abnormal Dische tests so far found with the tissues marked with an asterisk (cf ref 19)

The main purpose of this communication is to point out the need for careful checking of the absorption spectrum when using the test, particularly on materials not previously characterized, or where alternative assays are not carried out A subsidiary purpose is to suggest that where interference of this type is encountered, this may be partially diagnostic of unusual concentrations in the tissue of some of the substances listed, and it may be useful in some cases to carry out further tests for these compounds

I thank Prof Wesley Cocker and Dr R F Phillips for their advice

Variants of α_1-Acid Glycoprotein

IN a recent publication[1], α_1-acid glycoprotein, a human plasma glycoprotein, was shown to be polymorphic At pH 2 9, that is, near its isoelectric point, seven zones were observed if the mentioned protein had been isolated from pooled normal blood Moreover, it could be demonstrated that, following enzymatic removal of essentially all sialic acid, the modified pooled α_1-acid glycoprotein resolved at pH 4 8 into two major and a minor faster moving component[2]

In the present investigation experiments were carried out to study further the latter observation α_1-Acid glycoprotein was prepared from serum of normal adults and analysed by starch-gel electrophoresis at pH 4 8 Three types of patterns were observed (Fig 1) Type 1 distinguished itself in that the slower moving main band exhibited the maximum colour intensity, whereas Type 2 showed the maximum colour at the faster moving main band Type 3 revealed the mentioned two bands to be almost equally coloured To evaluate the three types of patterns with regard to the homozygous and heterozygous properties, further analyses are needed

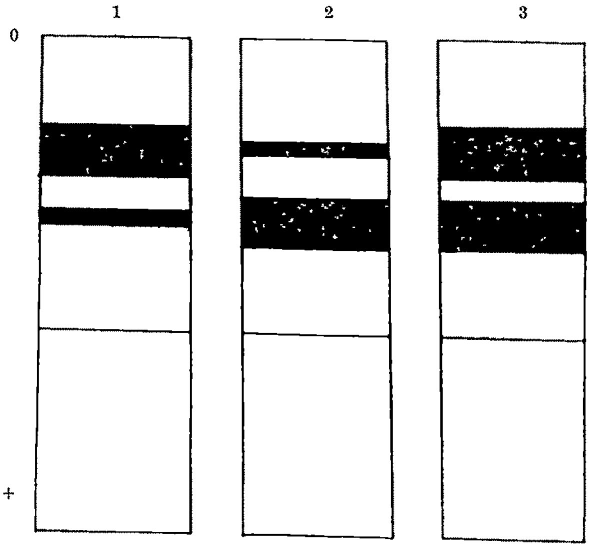

Fig 1 Starch-gel electrophoretic patterns of type 1 (1), type 2 (2) and type 3 (3) of α_1-acid glycoprotein modified with neuraminidase The electrophoresis was carried out at pH 4 8 in $\Gamma/2$ 0 02 acetate buffer The protein was applied at the positions indicated by ○ and migrated towards the anode (+)

An additional series of experiments was performed to establish the relationship between the patterns obtained at pH 2 9 using native α_1-acid glycoprotein and those observed at pH 4 8 utilizing native α_1-acid glycoprotein from which sialic acid had been removed enzymatically α_1-Acid glycoprotein preparations from apparently healthy adults were analysed by starch-gel electrophoresis at the mentioned two pH values As judged from the relatively small number of experiments it appeared that Types 1, 2 and 3 were largely associated with pH 2 9 patterns showing 7, 6 and 7 bands, respectively

Sorption of Copper by Wood Constituents

Belford, Myers and Preston[1] have directed attention to the fact that cellulose and wood absorb copper ions and that they appear to be regularly spaced on a grid pattern not corresponding to the unit cell of cellulose. Bayley and Rose[2] consider that α-cellulose has only a small cation binding power and that the complexes formed in wood consist of metal cations bound on the non-cellulosic constituents. Belford *et al.*[3] observed that in wood impregnated with preservatives containing copper-salts the middle lamella in particular stained very deeply with dithio-oxamide. In the work now reported the copper sorption of isolated wood constituents has been measured and the copper has been located in sections of treated wood by staining methods and electron microscopy.

'Milled wood lignin' prepared by the method of Björkman[4], wood α-cellulose (40 mesh) and purified cotton cellulose (40 mesh) have been examined for their copper binding capacity by the following method. A specimen of each material, 0·1–0·5 g, was shaken for 1 h in 5 ml. of 0·3 per cent copper acetate solution at about 20° C. The mixture was then filtered, the specimen washed with distilled water and the filtrate discarded. It was then washed three times with 10 per cent acetic acid and the combined acetic acid filtrates evaporated to dryness on a steam bath. The organic matter present was destroyed by heating on a hotplate with sulphuric–nitric acid mixture and the copper determined by the spectrophotometric rubeanic acid (dithio-oxamide) method of Center and MacIntosh[5]. The results are given in Table 1. A similar test on the residual lignin after the acetic acid washing showed that it retained no significant amount of copper.

These copper sorptions of cellulose are much lower than those recorded by Belford, Myers and Preston[1] and consistent with those observed by Michie[6], allowance being made for the different conditions by his equation (1). However, the absorption of copper by the milled wood lignin was, as shown in Table 1, much higher than for cellulose.

Table 1. Copper Sorption of Wood, Cellulose and Lignins (Grams of Copper per 100 g)

Eucalyptus regnans wood	0·033
Wood α-cellulose	0·040
Cotton—purified	0·038
E. regnans milled wood lignin	0·361
E. goniocalyx milled wood lignin	0·325
E. regnans methanol lignin	0·154
P. radiata compression wood milled wood lignin	0·258

It has been shown by me[7] that these milled wood lignins retained some uronic acid and that their infra-red spectra showed a band at 5·8μ attributable to carboxyl groups. Milled wood lignin from compression wood was exceptional in that this band was absent. No such band was observed in the spectrum of methanol lignin[8]. However, it may be seen from Table 1 that a significant sorption of copper by both these lignins occurred.

Examination of the infra-red spectra of copper-treated milled wood lignins showed only a small reduction in intensity of the band at 5·8μ. This indicates that, as would be predicted by Mitchie's equation for the conditions of our experiment, only a fraction of the carboxyl groups reacted with copper. Furthermore, there is extensive sorption of copper on lignin by some other mechanism. This suggests that groups other than carboxyl groups are also involved, but appears to be in accord with the view of Bayley and Rose that most of the copper sorption is on the non-cellulose constituents of the wood.

General confirmation of this conclusion has been obtained from the optical and electron microscopic examination of sections treated with a solution of copper sulphate. Fig. 1*a* shows a transverse section of *Pinus radiata* impregnated with copper sulphate and stained with dithio-oxamide. Fig. 1*b* shows the same section photographed between crossed nicols. It can be seen that copper is observed in or external to the layer S_1 of the secondary wall. An electron micrograph of a similar section of copper impregnated wood is shown in Fig. 2, the dark area indicating the presence of copper. It is apparent from the greater resolution in this picture that most of the copper was taken up by the primary wall *P* and intercellular layer. From ultra-violet absorption measurements, Lange[9] concluded that more than 70 per cent of the cell wall lignin is located in this region, so that these results are consistent with the suggestion that most of the copper taken up by the cell wall is attached to the lignin.

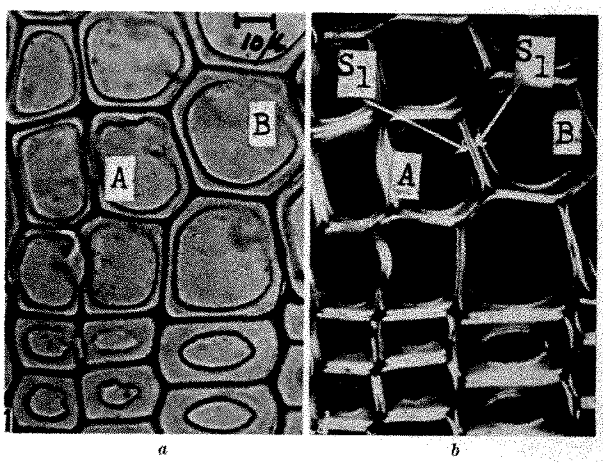

Fig. 1. Transverse section of *Pinus radiata* copper treated. (*a*) Stained with dithio-oxamide; (*b*) same section between crossed nicols

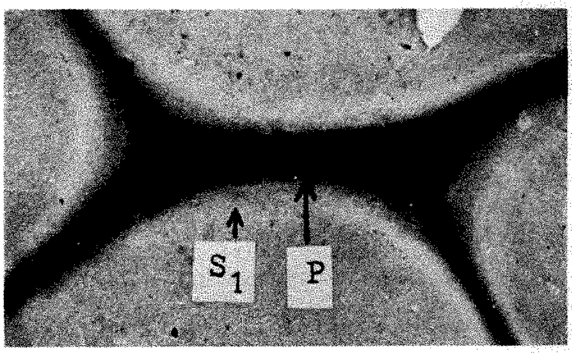

Fig. 2. Electron micrograph showing intercellular layer in copper-treated *Pinus radiata*

PHYSIOLOGY

Perinatal Changes in the Fluid and Electrolyte Content of Rat Liver

One of the difficulties of providing a satisfactory description of the fluid and electrolyte content of a tissue is the choice of a reference framework to which these contents can be related[1,2]. It is usually sufficient to relate the composition to the weight of the dry solids of the tissue, but in cases where some component of the dry solids may be subject to physiological variation, misleading conclusions may result from a comparison of data expressed in such terms. A striking example of variation in the composition of the dry solids is seen in the developing rat liver. Thus, recalculation of data reviewed by Shelley[3] shows that in this tissue the glycogen content increases from nil to more than 40 g per 100 g of the total dry solids during the last four days of gestation, and then falls to 5 g per 100 g within the first day after birth.

* FFDW, fat-free dry weight.

We have previously shown that there is a rapid increase in liver water and potassium contents relative to the fat-free dry solids during the first day after the birth of the rat[2]. Fenn[4] and Edlund *et al.*[5] have shown that quite large variations in the glycogen content of the liver of fed and fasted adult rats do not affect the liver water and potassium contents per unit dry solids, because deposition of glycogen in the cells is accompanied by an influx of water and potassium and vice versa. This observation would suggest that the change relative to the dry weight in the water and potassium content of the rat liver immediately after birth may not be entirely due to the varying contribution of glycogen to the total tissue solids. Nevertheless, the temporal association between the fall in the liver glycogen and the increase in the liver water and potassium per unit fat-free solids was sufficiently striking to warrant further investigation. We now report the protein, water, potassium and sodium contents of liver tissue taken from rats of differing perinatal ages.

The rats used were of local albino stock. The methods for the preparation of the tissue and for analysis of water, electrolytes and protein have been described previously[1,2,6,7]. The results, presented in Table 1, show that total protein forms a markedly decreasing fraction of the fat-free dry solids of rat liver during the late fœtal life. By the age of 12–24 h post-natal, however, the liver protein has increased to account once again for more than half the fat-free solids. These changes in protein content occur simultaneously with the marked perinatal changes in liver glycogen content[3]. However, 12–24 h old rats which were prevented from suckling had a lower liver protein content than did suckled animals of this age-group (Table 1), despite the fact that the unfed animals have a lower glycogen content[8]. The changes in protein content per unit fat-free solids that occur during the perinatal period are thus not solely a consequence of the changing contribution of glycogen to the total fat-free solids of the tissue.

Expressed in terms of the fat-free solids, both the water and the electrolyte content of the liver decrease during late fœtal life. In confirmation of our earlier findings[2], the water and potassium contents per unit fat-free solids were found to increase during the first day after birth and then to decline during later growth. On the other hand, when expressed in terms of the protein content there emerges a somewhat different picture of the changes in liver composition during the perinatal period. Thus, just before birth, the water content per unit protein increases; immediately after birth there is a large decrease in the water content, followed by a slower decrease which continues until adulthood. Both the sodium and potassium contents remain relatively constant during the last 3–4 days of fœtal life. During the first day after birth the potassium content falls significantly, but the sodium content only shows a significant fall later, that is, between the ages of 1 and 4 days. The changes in water and electrolyte composition during the 12–24 h immediately following birth are partly, but not entirely, accountable in terms of intake of food during this period. New-born rats which were not suckled during this time are found to have a higher water content per unit protein than fed animals (Table 1); the sodium and potassium contents of the fed and unfed rats are, however, not significantly different.

Table 2. Tissue Water Compartments of Developing Rat Liver

Age (days)		n	α_{Na}	(kg/kg protein) Extracellular water	Intracellular water
Fœtal:					
19–20		5	0·40±0·01	2·87±0·04	4·26±0·17
21		5	0·39±0·05	2·89±0·38	4·66±0·48
22		9	0·33±0·03	2·81±0·28	5·58±0·29
Post-natal:					
0·5–1·0	Fed	6	0·46±0·03	2·77±0·22	3·27±0·20
	Unfed	3	0·37±0·03	2·67±0·31	4·40±0·12
4–5		5	0·46±0·05	2·30±0·23	2·77±0·27
Adult		4	0·47±0·11	1·88±0·36	2·11±0·50

α_{Na} is calculated as (Na concentration in liver water)/(Na concentration in extracellular water) and is taken as a measure of the fraction of the whole water content of liver which is extracellular. The water contents of the extracellular and intracellular compartments can be calculated from α_{Na} and from the total water content of liver tissue (W)kg/kg protein from the relations:

Extracellular water $= \alpha_{Na}\ W$ kg/kg protein.

Intracellular water $= (1 - \alpha_{Na}\ W$ kg/kg protein).

In Table 2 are shown estimates of the quantities of liver 'extracellular' and 'intracellular' water per unit protein calculated on the two assumptions that all the liver sodium is extracellular and that the concentration of sodium in the blood plasma remains constant during growth[9] at a value of approximately 161 m.moles/kg water[10]. It can be seen that the volume of 'extracellular' water per unit protein remains constant during the last 3–4 days of fœtal life and the first day after birth; during this period the changes in total water content are largely due to changes in the quantity of 'intracellular' water per unit protein. During later growth the changes in the liver water content are due to decreases in the amounts of both 'extracellular' and 'intracellular' water per unit protein.

Our results indicate that very different pictures of the changes in liver water and electrolyte contents during growth are given by the use of different reference materials. It is clear that, for comparative purposes, an adequate description of the fluid and electrolyte composition of tissue requires a knowledge of the content of organic material as well as that of the water and minerals.

Strontium – Calcium Discrimination by the Human Placenta

The ability of the placenta to discriminate between strontium and calcium has been demonstrated by Comar *et al.* in double tracer experiments using rats and pigs[1]. They found that the strontium/calcium ratio of the fœtus was considerably less than that of the mother. In the case of rats, the strontium/calcium ratio of the fœtus was 0·55, and 0·65 times that of the mother, while for rabbits the fœtus had a strontium/calcium ratio 0·49 times that of the mother.

An estimate of placental discrimination in human beings has been made by Bryant and Loutit by comparing the stable strontium/calcium ratio of bones obtained from adults with that found in the bones of still-births and new-born infants[2]. The authors assume that there is no discrimination between blood and bone and that, therefore, the placental discrimination is measured by the ratio of strontium/calcium in the infant bone to the strontium/calcium ratio in adult bone. In the subjects studied by them this ratio was 200/320 or 0·62.

In this laboratory we have attempted to measure placental discrimination in human beings somewhat more directly, by determining the concentration of stable strontium in serum from blood taken from the fœtal and maternal sides of the placenta at birth. If the calcium concentration of the blood on either side of the placenta is assumed to be the same, then the ratio of the stable strontium concentration in the infant's serum to that of the mother is a measure of placental discrimination.

Approximately 10–20 c.c. of whole blood were taken from the maternal and fœtal side of the placenta immediately after birth and placed in sterile test-tubes. The blood samples were reamed and centrifuged and the serum removed. The serum samples were then sent to a commercial laboratory for stable strontium determination by neutron activation analysis.

The method used was to lyophilize known masses of blood serum, weigh the dried samples and enclose them in small aluminium-foil capsules. These samples, along with duplicates prepared from a standard strontium sample, were then sealed in an aluminium irradiation capsule and irradiated in a neutron flux of $\sim 1 \times 10^{13}$ n cm^{-2} sec^{-1} for about one week. After irradiation, the samples and standards were removed from the aluminium foils, dissolved in 16 N nitric acid in the presence of strontium carrier, and duplicate aliquots of the solution were taken for analysis. The strontium fraction was purified radiochemically by repetitive precipitation of $Sr(NO_3)_2$ with fuming nitric acid, followed by scavenging precipitations of $Fe(OH_3)$ and $BaCrO_4$. The strontium was recovered as $SrCO_3$ and weighed to determine the chemical yield. The strontium-85 (64-day half-life) content of each sample was then measured by γ-spectrometry.

The stable strontium content of each blood serum sample was determined from the respective strontium-85 counting rates and chemical yields of the samples and standards. The accuracy of individual analyses was estimated to be ± 10 per cent.

Table 1. STABLE STRONTIUM IN MATERNAL AND NEW-BORN BLOOD SERA AND THEIR RATIO

S.D.	±0·045	±0·034	±0·38

* Excluded in second average.

Results of the analyses of 17 pairs of samples are presented in Table 1. The average concentration of stable strontium in the mothers' sera was 0·10 μg/ml. with a standard deviation of 0·06 μg/ml. The average concentration of stable strontium in the new-born infants' sera was 0·08 μg/ml. with a standard deviation of 0·04 μg/ml. The ratios of the concentration of stable strontium in the serum of the new-born to that of the mother ranged from 0·26 to 2·53. The average and standard deviation of these ratios was 0·89 ± 0·57.

Because of the wide range of values obtained, the results were analysed statistically to see if any of the observations could be rejected on the ground that they were from a population with a different mean. Using a test devised by Dixon[3], the concentration of strontium in the mother of Case 14, and the new-born/maternal ratio of Case 13 were considered to be atypical of their respective populations and were consequently rejected. Average values for the new population of 15 cases were: mothers' sera 0·10 ± 0·05 μg/ml., new-borns' sera 0·07 ± 0·03 μg/ml., and new-born/mother sera of 0·82 ± 0·38.

If the assumption that the concentration of calcium in the new-born infant's blood is the same as that of the mother's blood, then the observed statistically significant difference in the strontium concentration of blood taken from the two sides of the placenta is an indication of strontium–calcium discrimination by the placenta. The magnitude of this discrimination is given by the ratio of the concentration of strontium in the new-born's serum to that in the mother's serum. This ratio was 0·82 ± 0·38, a result which is in general agreement with the findings of Bryant and Loutit that placental discrimination in human beings is less than that observed in rats and rabbits, but that it does occur.

If, on the other hand, the concentrations of calcium in the mother's and infant's blood are assumed to be different, and if further the placental discrimination is 0·62 as found by Bryant and Loutit, then the serum calcium of the mother can be expected to be 0·62/0·82 or 76 per cent that of the new-born. This increased concentration of calcium in the infant's serum as compared with that of the mother is consistent with Comar's findings in animal experiments[4], but requires verification in examination of human beings.

I thank Dr. Arthur Weinberg for obtaining the blood samples for this work.

Influence on Capillary Permeability of Lymph discharged from a Scald

ATTENTION has recently been directed to the protein permeability factor while investigating the pathogenesis of disturbance of the capillary permeability[1–4].

Investigations were carried out to determine the properties of lymph discharged from a scald. The lymph was collected from the popliteal nodes of rabbits (2·0–3·0 kg) and proteins were separated by paper electrophoresis (veronal buffer, μ0·023, *p*H 8·6). The influence of lymph on capillary permeability was investigated by introducing the lymph (0·1 ml.) intracutaneously into a rabbit previously injected intravenously with *T*–1824 or trypan blue (10 mg/kg). The scald was caused by dipping the hind-leg into water of $80 \pm 2°$ C for 1 min, and $50 \pm 0·5°$ C for 5 min.

In the lymph collected from 15 rabbits, 30 min and 24 h after the burn at 80° C (Table 1) protein concentration increased, the *A*/*G* coefficient decreased and β-globulin concentration increased ($P < 0·001$). In lymph obtained 24 h and, in several cases, 30 min after the burn, an additional globulin fraction was registered, located between β- and γ-globulin (β_2-globulin).

Results from scalds made at a lower temperature (50° C) with 10 rabbits were somewhat different. The protein concentration in the lymph increased ($P < 0·001$), but the *A*/*G* coefficient did not decrease; β-globulin concentration did not increase, nor was any additional β-globulin fraction discovered. At 50° C the actual swelling appeared after 2·0–2·5 h and continued increasing during 24 h. In contrast to the experiments at 80° C no destructive changes were noted in scalded paws.

The lymph obtained 24 h after scalding at 80° C in all cases caused acute disturbances in the capillary permeability. The influence of the lymph obtained 30 min after the scald was weaker. Lymph collected 24 h after scalding at 50° C did not provoke permeability derangement, while that obtained 30 min after scalding was active only in 7 out of 15 experiments.

Antihistamines ('Dimedrol', 'Alphadril') practically eliminated the influence of the capillary permeability of lymph collected 30 min after scalding at 50° and 80° C, and there was a slight weakening of the influence of the lymph obtained 24 h after scalding at 80° C. This might be explained by the participation of histamine in the first phases of the inflammation and the subsequent inclusion of active globulins[5,6].

Table 1. ELECTROPHORETIC ANALYSIS OF LYMPH

	Albumin (%)	Globulins (%)					*A*/*G* coeff.	Protein (g/%)
		α_1	α_2	β_1	β_2	γ		
Before burn	50·2	6·9	12·9	14·0	—	16·0	1·03	3·2
30 min	45·7	7·0	11·1	11·5	7·7	17·0	0·87	3·4
P	< 0·001	< 0·5	< 0·1			< 0·5	< 0·001	< 0·01
24 h	43·2	7·3	11·2	10·0	10·7	17·6	0·78	3·8
P	< 0·001	< 0·5	< 0·5			< 0·5	< 0·001	< 0·001

The appearance of unusual β-globulins in the rabbit's lymph during scalding coincides with previous investigations made in our laboratory[7]. It seems that during inflammation not only are the existing globulin permeability factors activated but also unusual globulins are formed[8].

In spite of intensive swelling at the site of the scald at 50° C, the lymph after 24 h did not cause capillary permeability disturbances and did not contain histamine and globulins with unusual electrophoretic mobility. It is possible that under the influence of moderate temperatures the mediators causing capillary permeability derangement in rabbits, just as in rats, are other factors affecting permeability[9,10].

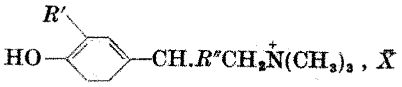
PHARMACOLOGY

Quaternized Sympathomimetic Amines

IN their paper on sympathomimetic amines, Barger and Dale[1] described the action of hordenine (the *N* : *N*-dimethyl derivative of tyramine), and showed that the quaternary derivative, hordenine methiodide (1; $R' = R'' = H$), had a nicotine-like action.



(1)

($\overset{-}{X}$ = chloride, bromide or iodide)

They also found that the trimethylammonium derivative (1; $R' = OH$, $R'' = H$) of dopamine had a stronger nicotine-like action, about as strong as nicotine itself.

These compounds, together with the trimethylammonium derivative (1; $R' = R'' = OH$) of noradrenaline, have recently been made again by our colleague, Dr. A. M. Creighton, and have been compared with nicotine on the blood pressure of a spinal cat, and on other preparations. The full results will be described in detail elsewhere. Calculations were made in terms of active base. The general statement can be made that: (1) hordenine methiodide was found to be approximately equal to nicotine in pressor action; (2) the quaternary derivative of dopamine was about four times as active as nicotine; (3) the corresponding derivative of noradrenaline possessed only one-tenth of the action of nicotine. Thus the nicotine-like action was greatly reduced when $R'' = OH$.

These results led us to compare the pressor effects of ethyltrimethylammonium bromide with that of choline chloride. Both compounds have a pressor action in the spinal cat which is abolished by hexamethonium. Ethyltrimethylammonium was found to be about 40 times more active than choline expressed in terms of active base. Thus in this pair of compounds, also, the presence of an

–OH group attached to the β-carbon atom greatly reduced the nicotine-like action.

Skin Reaction to Intradermal Injection of Rare Earths

The availability of highly purified rare earths, elements 21 and 58–71, has stimulated interest in their chemical and physical properties[1]. Haley *et al.*[2–6] have examined their biological effects and reported that although they can produce non-specific liver damage they exert their greatest toxicity on the ocular and dermal tissues. However, even this damage can be repaired with time and results in no permanent injury. Recently, it was observed that the intradermal injection in guinea pigs of 0·05 ml. aqueous solutions of 1×10^4–1×10^6 concentrations of praseodymium, neodymium, europium, dysprosium, holmium, erbium or lutetium chlorides resulted in the formation of 2-mm diameter nodules containing crystalline deposits (Fig. 1). Observation for periods of 45 days showed no decrease in nodule size or any resorption of the crystalline deposits.

Differential staining of histological sections with Dominici, Prussian blue and von Kossa stains indicated the presence of histiocytes and foreign body giant cells surrounding the crystals with fibroblasts and granulation tissue extending into the area. There was an indication of calcium but no iron in the crystals. Considering the total amount of rare earth injected, 0·05–5 μg, further analysis was not possible to establish the exact composition of the crystals. Furthermore, analytic procedures for the rare earths are non-specific and the presence of other ions would interfere to the extent of negating a more complete analysis. Of prime importance is the tissue reaction to such low levels of element and its implication to industrial prevention of injury during chemical processing. A re-evaluation of the other members of the series is being undertaken to determine whether or not they also can induce such changes in tissue at the same concentrations.

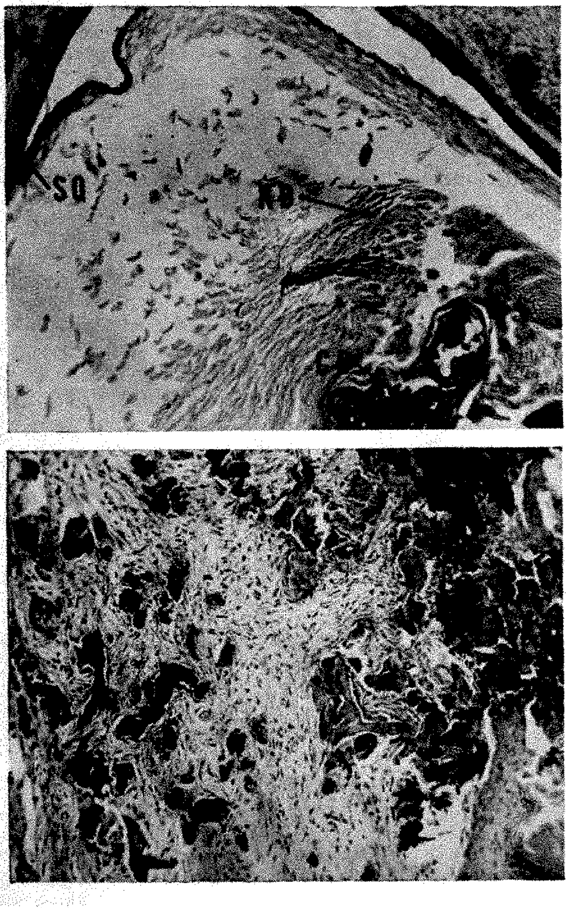

Fig. 1. Dermal reaction to injection of 0·05 ml. of 10^6 lutetium chloride in guinea pigs. Upper photomicrograph illustrates presence of keratotic debris (*KD*), stratified squamous epithelium (*SQ*) and crystalline deposits (*CD*). Lower photomicrograph illustrates foreign body giant cells in lower right-hand corner of upper photomicrograph

Some Biological Properties of 'Ibufenac', a New Anti-rheumatic Drug

For some years we have been investigating the biological properties of substituted phenylalkanoic and phenoxyalkanoic acids and related compounds. We wish to describe briefly the properties of one of these, 'Ibufenac', which Chalmers and Duthie have recently shown to be effective in the treatment of rheumatoid arthritis[1].

'Ibufenac' (British Pharmacopœia Commission approved name) is 4-isobutylphenylacetic acid, a colourless crystalline solid, melting-point 85°–87° C. It is relatively insoluble in water, but readily soluble in most organic solvents.

This compound has been tested by the oral route in a number of different anti-inflammatory and analgesic tests, and the results obtained in some of these are reported here. The anti-inflammatory activity of 'Ibufenac', as assessed by an ultra-violet erythema test in guinea pigs[2], is 2–4 times that of aspirin. Its analgesic activity, measured by a modification of the method described by Randall and Selitto[3], is also 2–4 times that of aspirin. The antipyretic activity is approximately 4 times that of aspirin when measured over a 4-h period in the yeast-fevered rat. The minimal effective dose of 'Ibufenac' for reducing thurfyl nicotinate ('Trafuril') erythema in man is 960 mg. The compound exhibits no glucocorticoid activity when tested in the mouse by a modification of the method described by Silber[4].

The acute oral LD_{50} in mice is approximately 1,800 mg/kg. Rats given 250 mg/kg daily for 6 months remained in good health and the only abnormality at necropsy was slight enlargement of the liver, kidneys and adrenal glands, which was reversible. Dogs were given daily oral doses of 40, 80 and 160 mg/kg for 6 months; some animals receiving 80 and 160 mg/kg showed simple renal hypertrophy, but kidney function was normal and there was no histological abnormality; gastric damage was found only at the highest dose.

Studies with the compound labelled with carbon-14 in the rat indicated that it is well absorbed from both the stomach and intestine. In human subjects, after doses of 640 mg, detectable levels of 'Ibufenac' were present in the blood within 30–60 min, rising to a maximum of 2–4 mg/100 ml. in 2–4 h. Small, but detectable, amounts were present 8 h after the dose.

The same two principal metabolites were found in the urine of the rat, rabbit, dog and man. Neither of these metabolites (extracted from the urine of subjects receiving 'Ibufenac') had analgesic or anti-inflammatory activity when tested by the oral route in animals. Preliminary metabolic studies in men and dogs indicate that the compound does not accumulate in the body.

HÆMATOLOGY

The Camel's Erythrocyte

THE camel's ability to live without water for long periods is outstanding[1,2,4,6]. It can lose about 30 per cent of its body-weight during dehydration in the desert and still move about[12]. A dehydrated camel can regain its losses of water (about 30 gallons) in about 10 min and resume its normal appearance; despite the large flow of water into the bloodstream its erythrocytes are not hæmolysed. In human beings the entry of 600 ml. of water into the circulation will produce hæmoglobinuria[11]. It is also known that cattle (in hot environments) deprived of water and then given large amounts of it may develop hæmoglobinuria. This, however, has never been observed in camels, according to statements made by camel raisers.

This unusual erythrocyte behaviour initiated the investigation of the rate of swelling and the osmotic resistance of the camel's erythrocyte to hypotonic solutions. Camels in Israel are of the single-humped 'dromedary' variety; they are found mainly in the hot and arid southern Negev. In the work recorded here, blood samples from 20 clinically healthy camels were compared with blood samples from 20 Holstein–Friesian adult healthy cows. Heparin served as anti-coagulant.

The rate of swelling of the erythrocytes in hypotonic buffered sodium chloride solutions and their osmotic resistance were carried out according to a modification of the Guest and Wing method[2]. The modification is based on the use of microhæmatocrit centrifuge and tubes[7,8]. One volume of packed erythrocytes is placed for one hour into test tubes containing four volumes of sodium chloride solution, with varying concentrations, and buffered to *p*H 7·3. The successive steps in the changing concentrations of the salt solutions used in the series were 0·05 in the range of 0·9–0·5 per cent and 0·025 per cent in the range of 0·5–0 per cent. Microhæmatocrit tubes were then filled with the diluted blood samples and centrifuged for 5 min at 12,000 r.p.m. The values for the volume of cells in the hæmatocrit tubes were measured and calculated in percentages on the basis of the first tube (0·9 per cent sodium chloride solution) the hæmatocrit value of which was taken as 100 per cent.

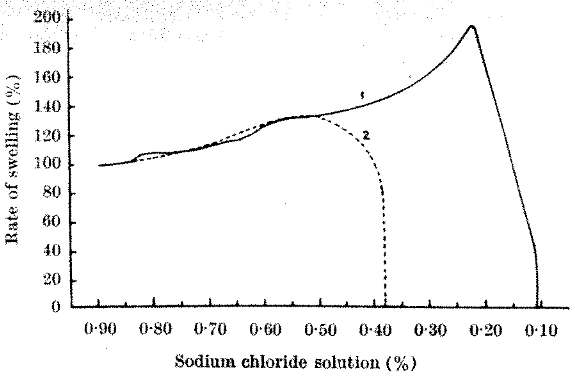

Fig. 1. Changes in volume of erythrocytes in hypotonic buffered salt solutions. 1, Normal adult camels; 2, normal adult cattle. (The initial hæmatocrit value counted as 100 per cent)

Fig. 1 and Table 1 show the osmotic behaviour of the camel's and cow's erythrocytes in hypotonic solutions. At first the swelling of all the cells raises the hæmatocrit values up to the point where the first trace of hæmolysis appears (minimal osmotic resistance), and then falls when the loss of cells by hæmolysis exceeds the increases in volume of the unhæmolysed cells. The camel's erythrocytes are by far more resistant to hypotonicity than the cow's and its minimal osmotic resistance was achieved, therefore, in a much lower concentration of sodium chloride solution (0·22 per cent sodium chloride, camel; 0·55 per cent, cow).

During the first decrements of the sodium chloride solution (down to 0·55 per cent) the camel's erythrocytes show the same rate of swelling as those of the cow. However, the maximal rate of erythrocyte swelling exceeds by far that of the cow (196 per cent of initial volume for the camel and 133 per cent for the cow (Fig. 1)).

Complete hæmolysis of the camel erythrocytes was achieved at the very low sodium chloride solution of 0·11 per cent, which deviates from the findings of Ponder[9], while in cattle complete hæmolysis occurred at a concentration of 0·36 per cent sodium chloride.

It can be observed from the curve (Fig. 1) that from a concentration of sodium chloride of 0·9 per cent down to 0·35 per cent a relative linear increase in erythrocytes volume occurs, but at a less-steep angle than that obtained for the perfect osmometer[7,10]. This deviation from the perfect osmometer curve of the cell swelling suggests that this may be the result of the excessive binding of water by intracellular components[1,5]. From a concentration of 0·35 per cent sodium chloride down to 0·22 another type of behaviour is observed, expressed in a steeper increase in the erythrocyte volume. This further angle increase in the curve of camel cell swelling attains the perfect osmometer.

Katchalsky *et al.*[3] attribute to the human erythrocyte membrane visco-elastic properties. When applying this to the animal erythrocytes one may presume that the elastic property of the camel red cell is smaller than that of the cattle and, therefore, stressing of the membrane does not cause counterstress as in a membrane with primarily elastic properties.

The cow erythrocytes, too, are far from exhibiting ideal osmometric behaviour. This may be seen from both their

Table 1. HEPARINIZED NORMAL CAMEL AND CATTLE BLOOD DILUTED WITH BUFFERED SOLUTIONS OF SODIUM CHLORIDE OF DIFFERENT CONCENTRATIONS

water-binding properties and membrane resistance, with their higher elastic component, as compared with the camel. The swelling of the corpuscle causes a counterstress in the membrane which in turn counterbalances the extent of the swelling correspondingly; at a certain amount of swelling, the elastic wall ruptures under the additional stress. This contrasts with the behaviour of the less elastic and more viscous properties of the cell membranes of the camel erythrocytes.

It would appear, therefore, that the capability of the camel blood to resist high dilutions is due to a number of causes, among these the increased binding capacity of the erythrocyte components for water and the large swelling capability shown by these corpuscles.

Investigations on the cell membrane components and its structure are being carried out at the present time.

I thank Mr. I. Horth and K. Lobel for their assistance.

IMMUNOLOGY

Immunological Changes and Therapeutic Effects of Convalescent Serum after Injury by Burns

Immunological changes after burns, induced by the breakdown of damaged skin tissues, were discussed half a century ago. Recently, reports from American and Russian authors seem to indicate the formation of antibodies against body-own burned skin, and also for the therapeutic value of convalescent serum. We have tried to confirm these findings.

Rabbits, guinea pigs, rats and mice were subjected to exact reproducible burns of third degree and 25 per cent extent in general anæsthesia. Sensibilization was performed by the intraperitoneal injection of extracts obtained from burned rabbit, guinea pig and rat skin, excised 2–96 h after a burn, or by implantation of excised burned skin into the peritoneal cavity of rats or guinea pigs. Convalescent serum from rabbits and rats was obtained by bleeding 3–4 weeks after the burn.

For testing the formation of antibodies, the following serological methods were used: Ouchterlony technique, Schultz–Dale technique, complement-binding-reaction, skin sensibilization test. For determination of the effects of convalescent serum, the following criteria were used: blood cell counts, plasma histamine-level, blood pressure, water content of the parenchymatous organs in rats, finally the survival time and rate after, if untreated, lethal burns in mice, and the mortality rate after injection of burned skin extracts.

In the Ouchterlony technique, all sera of sensitized guinea pigs gave positive reaction with extracts of burned skin from rabbits and with some extracts of burned skin from guinea pigs. All sera of sensitized rabbits reacted negative with extracts of burned rabbit skin. All sera of sensitized animals, both guinea pigs and rabbits, gave negative reaction with normal skin extracts, except one serum of a guinea pig.

In the Schultz–Dale preparation, after adding extracts of burned skin, the sensitized guinea pig uterus showed contractions of 30–75 per cent more than after addition of normal skin extracts. It is unlikely that histamine was responsible for this effect, since the burned skin extracts contained less histamine than those of normal skin.

Skin reactions could not be induced in sensitized guinea pigs by burned skin extracts. Complement-binding reactions gave negative results.

The determination of the effects of convalescent serum, injected in 2-ml. amounts intraperitoneally to rats subjected to burns as already described, in comparison with same amounts of normal rat serum or 0·9 per cent solution of sodium chloride, gave the following results.

Post-traumatic leucocytosis was reduced by normal and convalescent serum in the same degree; but not by sodium chloride. The histological picture in liver and kidney was not influenced by the application of the sera. The increase of water content of organs, well known after burns, was reduced by convalescent serum in the liver, with slight significance. Plasma histamine increase 1 h after burn was nearly completely inhibited by normal and convalescent serum, without significant difference. Fall in blood pressure, as measured from the rat tail, was not altered by the sera or by sodium chloride. Convalescent serum injected in guinea pigs did not show any increase of the survival time and the survival rate of these animals.

Survival time of lethally burned mice was prolonged by sera far more than by sodium chloride, but without any difference between the sera. Significant influence on blood pressure and on survival time and rate was only observed after injection of a protease inhibitor ('Trasylol ^{R}').

Our findings support the hypothesis of the development of immunological changes after burns, but they give no evidence for any protective action of convalescent serum in the therapy of post-burn disturbances. The interval between trauma and excision of burned skin, and also the method of extraction, seem to be of special importance for the results obtained in serological techniques.

Effect of Neonatal Thymectomy, Bursectomy and Thymo-bursectomy on Hæmagglutinin Production in Chickens

Since the demonstration by Glick *et al.*[1] that bursectomized chickens have a reduced ability to produce antibodies to *S. typhimurium*, a large body of evidence has shown the importance of the bursa of Fabricius in the development of antibody-forming capacity in birds. Mammals thymectomized in early life are unable to manufacture antibodies against certain antigens[2]. However, the role of thymus in the development of immunological potential in chickens is not clearly established. The work recorded here compares the relative roles of thymus and bursa in hæmagglutinin production in chickens.

Rhode Island Red chickens were thymectomized, bursectomized and thymo-bursectomized 2 days after hatching. One group of 9-week-old bursectomized chickens was grafted with bursa from newly hatched chickens implanted between parietal and visceral peritoneum. A second group was grafted with bursa from 8-week-old birds. An additional group of chickens was bursectomized at the age of 8 weeks. At 10 weeks all groups were

Table 1. ANTIBODY RESPONSE OF NORMAL, THYMECTOMIZED, BURSECTOMIZED AND THYMO-BURSECTOMIZED CHICKENS

Group	Age at time of operation	No. of chickens*	Grafting (age of bursa donor)	Mean peak agglutinin titre ($\log_2$)
Control	—	12/12	—	9·22 ± 0·79

Thymo-bursectomized	2 days	6/8	—	2·92 ± 2·14
Bursectomized	8 weeks	9/9	—	10·12 ± 0·40
Bursectomized	2 days	10/16	—	3·61 ± 2·81
Bursectomized	2 days	17/17	2 days	8·21 ± 3·03
Bursectomized	2 days	15/19	8 weeks	6·12 ± 1·19

* Numerator, No. of chickens with hæmagglutinins; denominator, No. of chickens in group.

† Five birds had < 0·2 g, and two birds < 0·7 g, of residual thymus. Thymus weights in control chickens at 11 weeks were between 1·9 and 2·8 g.

injected with 1·5 ml. of a 10 per cent suspension of human O erythrocytes. Seven days later the birds were bled and hæmagglutinin determinations were carried out as described previously[3]. Since chicken antisera undergo *in vitro* changes on standing[4]; all titrations were made 5 days after bleeding. The cloaca and neck were examined *post mortem* for the presence of bursal and thymic residua.

The findings are summarized in Table 1. Birds surgically bursectomized or thymo-bursectomized at 2 days showed very low hæmagglutinin titres. Bursectomy at 8 weeks did not affect antibody-producing capacity, however. These results agree with those of Chang *et al.*[5], and Mueller *et al.*[6], who found that only early removal of the bursa impaired the antibody response. Totally or partially thymectomized chickens showed normal hæmagglutinin production. The bursal implants clearly enhanced the reactivity of bursectomized chickens, and new-born bursa was somewhat more effective than 8-week bursa. Histological examination of the methyl-green-pyronine stained sections of spleens has revealed marked proliferation of plasmocytic cells in normal and thymectomized chickens 7 days after immunization. Plasma cells were seen also in the spleens of bursectomized birds, but there was no proliferative response following antigenic stimulus.

Bursa-homografts were rejected by bursaless chickens with great uniformity. Eight days after grafting, that is, 3 days after the injection of heterologous erythrocytes, the periphery of the graft had been replaced by connective tissue, and the adjacent areas were infiltrated with mononuclear cells. Bursal follicles in the central part of the graft were still recognizable as such, but their cellular make-up had been totally destroyed (Fig. 1).

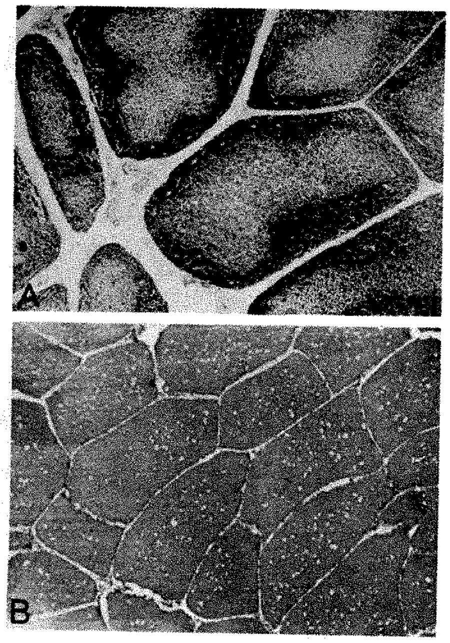

Fig. 1. *A*, Bursa of Fabricius from 8-week-old chicken. Normal appearing follicles. Basement membrane separates the cortex from the medulla; *B*, bursa-homograft at the eighth day. Cellular make-up of follicles is totally destroyed. (× *c*. 20)

Bursa of Fabricius may share in birds some of the functions[7-9] performed in mammals by the thymus alone[10,11]. The present work shows that neonatal thymectomy does not interfere with hæmagglutinin production in chickens. On the other hand, neonatal bursectomy suppresses antibody formation, but has no effect on homograft rejection. It is generally assumed that bursa acts as a source of lymphoid cells which are distributed to other tissues of the lymphoreticular system. Our observation that antibody-producing capacity is restored in bursectomized chickens by bursal homografts could be taken as evidence in favour of this supposition, but by no means rules out a hormone-like function of the bursa. In support of this latter contention Glick[12] has reported that injections of saline extract of acetone-dried bursæ enhances to some extent the antibody response to sheep erythrocytes in bursectomized chickens.

HISTOCHEMISTRY

Blocking the Ninhydrin – Schiff Reaction with Copper Ions

THE ninhydrin–Schiff reaction of Yasuma and Ichikawa[1] has been widely used as a histochemical method for the detection of α-amino-acids[2,3] and recently it was applied quantitatively in cytochemistry by Rappay and Törk[4]. Whereas the detailed mechanism of the reaction has not been completely verified at the histochemical level, there is now fair agreement as to the specificity of the reaction for proteins[5]. The present experiments endeavour to show that colour production may be markedly affected by the purity of the reagents used.

Blood from adult individuals of *Amblystoma mexicanum* (axolotl) and *Pleurodeles waltlii* (a newt), obtained by decapitation and washed thrice with physiological saline, was smeared on slides, dried at room temperature, and fixed in Carnoy's fluid and 80 per cent cold acetone for 15 min. For some slides the fixatives contained 10^{-2} M of copper sulphate while others were placed in a 10^{-1} M copper sulphate solution for 30 min. Both untreated slides and those treated with copper sulphate were incubated for 16 h in 0·5 per cent ninhydrin ('Ninhydrinum', $C_9H_4O_3H_2O$, mol. weight: 178·15) dissolved (*a*) in absolute alcohol free from metallic salts; (*b*) in absolute alcohol saturated with copper sulphate; (*c*) in 96 per cent alcohol with copper sulphate added to it in final concentrations

Table 1. EFFECT OF BLOCKING THE REACTION WITH COPPER IONS

Erythrocyte	Copper sulphate (in molar concentration)									
	Added to fixative		Applied after fixation		In alcoholic ninhydrin solution (0·5%)					
					Absolute		96 per cent			
	0	10^{-2}	0	10^{-1}	0	Saturated	0	10^{-2}	10^{-4}	10^{-6}	10^{-8}
Nucleus	+ + +	+ + +	+ + +	+ + +	+ + +	–	+ + +	–	–	±	+ + +
Cytoplasm	+	+	+	+	+	–	+	–	–	–	+

+, Colour intensity; –, negative reaction; ±, questionable reaction.

ranging from 10^{-2} to 10^{-8} M. Treatment with ninhydrin was followed by immersion in Schiff's reagent for 30 min.

From Table 1 it can be seen that in a medium free from copper sulphate the ninhydrin–Schiff reaction gave an intense colour to nuclei and somewhat less staining of the cytoplasm of erythrocytes from the two amphibian species studied; further, that copper sulphate, whether added to the fixative or applied after fixation, was without influence on colour intensity. On the other hand, both nuclear and cytoplasmic stainability were remarkably dependent on the copper sulphate concentration in the ninhydrin solution. Apparently, concentrations of 10^{-2}–10^{-6} M copper sulphate were capable of completely suppressing the reaction.

The suppressive action of copper sulphate may be explained in several ways. One possibility is that copper ions attach to the reactive sites of amino-acids participating in the reaction, blocking the formation of aldehyde groups. Against this explanation is the fact that treatment with copper sulphate preceding incubation in ninhydrin had no influence on aldehyde-group formation and the subsequent colour reaction. Another possibility considered is that ninhydrin itself becomes in some way bound to copper sulphate. This seems improbable in view of the low concentration of copper sulphate present in the incubation mixture in relation to that of ninhydrin. The most likely explanation appears to be that the copper ions, as metallic salts, are responsible for altering the reaction mechanism, which generally would be an oxidative process. It merits mentioning that zinc sulphate also suppresses formation of the aldehyde groups necessary for the reaction to occur.

On the basis of the experimental evidence summarized here, the ninhydrin–Schiff reaction, particularly when used for quantitative purposes, calls for the use of high-purity reagents free from metallic salts.

New Data concerning Histochemical Structure of the Myocardium

TRANSVERSE striation of muscle fibres in the heart has been known for a long time; but two problems in relation to this peculiarity of myocardium are not as yet solved. The first problem is concerned with the histochemical nature of transverse striation and the second with the functional significance of the individual components of myofibrils.

This communication deals with the distribution of protein and glycogen in cardiac muscle fibres examined with the aid of polarizing and phase-contrast microscopes.

Investigations were provided on 10 intact dogs, the contracting hearts of which were fixed in Shabadash's fixator (calcium nitrate, 0·9 g; copper nitrate, 1·8 g; 96 per cent ethanol, 90 ml.; 40 per cent formalin, 10 ml.) injected into the coronary vessels. The serial paraffin sections (7μ thick) were stained for total protein using Danielli's tetrazonium method and for glycogen with the aid of periodic acid–Schiff reaction following Shabadash[1,2]. Incubation of the control sections in benzoilchloride and in diastase, respectively, prevented the positive reaction for protein and glycogen. In order to compare histochemical and histological structures of myofibrils the parallel sections were stained with hæmatoxylin and eosin and with iron hæmatoxylin. The slides were examined under the light microscope, polarizing microscope and in phase-contrast microscope.

It was established that ordinary muscles of myocardium in intact dogs have an uneven distribution of protein. Separate groups of fibres show more pronounced reaction for proteins than the others, where it is manifested less significantly. The same picture is observed in Purkinje fibres. In comparison with the ordinary muscle fibres of myocardium, the fibres of the conduction system contain more protein. This may be the reason for the absence of transverse striation in these fibres, although it could be readily seen in the polarized light. The transmission of Purkinje fibres into usual muscle fibres occurs gradually without any visible boundaries and is followed by decrease in the intensity of protein reaction. Usual light microscopy reveals in these instances manifested transverse striation of the cardiac muscles.

Histochemical investigations of the separate muscle fibres in polarized light as well as under the phase-contrast microscope have shown that the anisotropic disks are denser and correspondingly richer in protein, whereas isotropic disks contain small amounts of protein. In the central portion of these disks, however, which corresponds to the *Z*-line, the protein reaction is more manifested. In anisotropic disks it is possible to reveal three lines: two lateral lines are separated from each other by a pale zone with the third *M*-line in its centre (Figs. 1 and 2).

The intercalated disks are characterized by large, but not always constant, amounts of protein. Some of them react more actively and can be readily revealed against the background of the transverse striation, whereas the others are scarcely seen in the light microscope. Such intercalated disks, which are isotropic, may be found with the aid of a polarizing microscope even in those cases when the usual light or phase-contrast microscopy fails to reveal them. Furthermore, a polarizing microscope makes possible a study of structures of intercalated disks in unstained sections. This may be utilized as a new method for their detection (Figs. 3 and 4).

Correlations in the distribution of protein and glycogen in myocardium have demonstrated that these substances are localized predominantly in the same sites of Purkinje fibres of the heart and typical cardiac muscle fibres. At the same time, it is always possible to reveal essential differences in the form of their distribution in the microstructures of myofibrils. Glycogen in the sarcomeres of

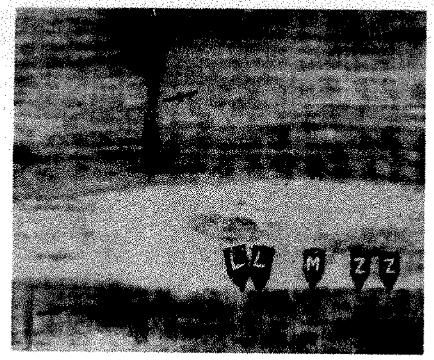

Fig. 1. Phase-contrast microscopy of cardiac muscle fibres of the dog. Reaction for protein. Arrows with letters indicate separate stripes of sarcomeres, simple arrows indicate intercalated disks. Objective 90, ocul. 10 (× c. 1,200)

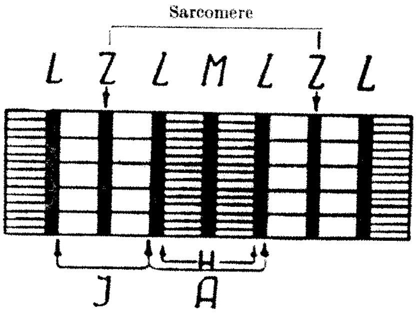

Fig. 2. A scheme of protein distribution in sarcomere. The dark areas correspond to the intensity of the reaction for protein

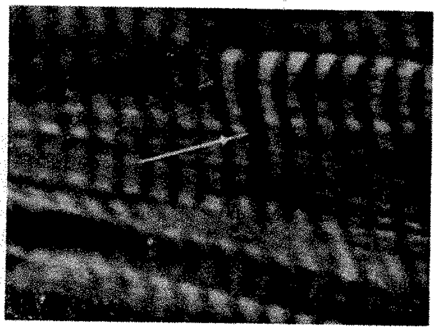

Fig. 3. Microphotograph of the dog's cardiac muscle fibres in polarized light (viewed with crossed polarizer and analyser). The intercalated disks are isotropic (indicated with arrow); the section is not stained. Objective 90; ocul. 10 (× c. 1,700)

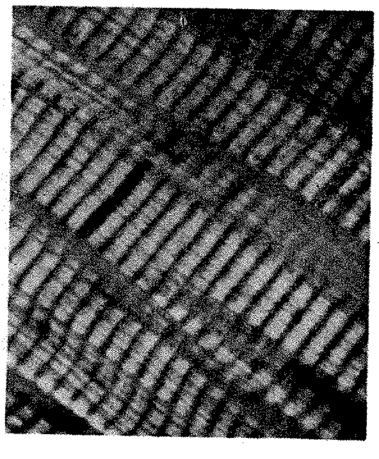

Fig. 4. Microphotograph in polarized light (viewed with crossed polarizer and analyser) of the dog's cardiac muscle fibres. Reaction for protein. Inserted disks and Z-stripes contain comparatively large amounts of protein. Objective 90; ocul. 10 (× c. 1,200)

individual muscle fibres is distributed differently. In some fibres it is predominantly accumulated, as well as protein, in A-disks and Z-lines (Fig. 5*a*); in other fibres it is located in I-disks (Fig. 5*b*). Different distributions of glycogen in sarcomeres are dependent on the functional states of muscle fibres during fixation. In the intercalated disks glycogen is localized essentially along the margins whereas protein has a diffuse distribution throughout the entire disk, leaving sometimes narrow and pale space in the centre. The latter seems anisotropic in polarized light (Figs. 1, 3, 4 and 5).

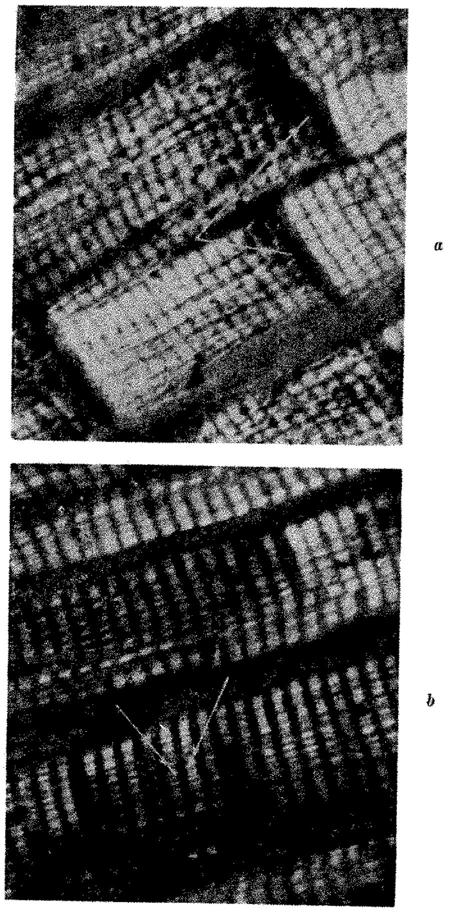

Fig. 5. Microphotograph in polarized light (viewed with crossed polarizer and analyser) showing unevenly distributed glycogen in the micro-structures of functionally different areas of myocardium. *a*, Contracted fibres. In the centre of the figure one can see two muscle fibres with different content of glycogen. The latter is manifested in Z-stripes and A-disks. The arrows indicate the distribution of glycogen at the margin of the intercalated disk. *b*, Enfeebled fibres. Glycogen is accumulated predominantly in I-disks; in Z-stripes and in A-disks it is contained in less significant amounts. The contents of glycogen in I-disks are shown by the double arrows. Objective 90; ocul. 10 (× c. 1,200)

Thus, these observations show that protein in myofibrils is distributed unevenly and is accumulated in the intercalated disks, Z-stripes and in three lines of anisotropic disks. The centre of these coincides with the M-line, whereas the two marginal ones separated by an H-zone do not have a special name. I propose to name them L-lines (the first letter of the Latin word, lateralis).

Unevenly distributed protein and glycogen[3] in microstructure of myofibrils may be considered as an essential cause of transverse striation in the muscle fibres of the heart.

Comparatively high contents of protein and glycogen in Z-lines and in the intercalated disks suggest active energetic participation of these structures in the contractile activity of myofibrils. This is confirmed by the literature, which presents information on the presence of various enzymatic systems in *Z*-lines and in the intercalated disks[4-6].

RADIOBIOLOGY

Relative Biological Efficiency of Negative μ-Mesons and Cobalt-60 γ-Rays

THE concept of the relative biological efficiency of different radiations is one that has considerable practical and theoretical interest, and an extensive literature exists which describes in detail the problems of the determination and interpretation of relative biological efficiencies[1]. Variations in the relative biological efficiency of different radiations are attributable to differences in their ion density or linear energy transfer, defined as the rate of energy loss in eV/μ of irradiated material. Recently an opportunity arose at this laboratory to determine the relative biological efficiency of a highly energetic radiation with low linear energy transfer characteristics—an almost pure beam of μ^- mesons. These have a mass of about $200m_e$, one negative charge, and an energy range in this experiment of 2–8 GeV (with a peak at 4–6 GeV).

The muons were generated in the Brookhaven alternating gradient synchroton. A beam of protons (energy ~ 28 GeV) was brought on to a beryllium target placed in the machine. Negative pions produced in the target between the energies of 7–9 GeV in the forward direction were bent through the magnet following the target and out of the machine at an angle of 9°. After passing through an entrance lens of 4 quadrupole magnets, the beam was confined by a series of 5 pairs of quadrupoles placed about 25 ft. apart[2]. The pions were concentrated in a spot of radius ~ 3 in., and the decay angle of the muons was small enough so that almost all the decay muons remained in the 6-in. radius which was available after the entrance. Roughly 10 per cent of the pions decayed before the beam was filtered through 7 ft. of concrete, which removed most of the pions and left the muons essentially unchanged except for about a 1-GeV loss of energy. With about 2×10^{11} protons striking the target an intensity of the order of 10^8 muons/pulse was obtained, the pulse rate being once every 2·5 sec.

Energy loss from muons occurs primarily through electromagnetic interactions-by direct ionization, and by the production of knock-on secondary electrons. The energy deposition in the *Tradescantia* tissues used in the present experiment could be calculated, since the elementary composition of the tissues[3], and the energy loss/gm/cm^2 in the different elements, were known. The average linear energy transfer was 195 eV/μ and on this basis a low relative biological efficiency would be predicted. The precise range of energy of the knock-on electrons, and hence of the range of linear energy transfers, was not known.

The biological test system used was that of somatic mutation induction in staminal hair cells of a diploid clone (02) derived from a variety of *Tradescantia occidentalis*[4,5]. This clone was heterozygous for genes controlling anthocyanin pigment, heterozygous cells being blue, homozygous recessive mutant cells red and easily distinguishable. A given inflorescence contained a large number of serially arranged buds—one flower emerging daily. Each flower had six stamens, and each stamen approximately 55 hairs. Staminal hairs are chains of single cells and their pattern of growth is as follows. A single cell in the filament becomes meristematic and becomes the terminal cell of the hair, continuing to divide until the mature hair (20–30 cells) is formed behind it. The subterminal cell always divides once after its formation, and occasionally an intermediate cell also divides. The mutations were almost certainly chromosomal deletions and recognition of a mutant phenotype was dependent on the loss of a particular fragment from that cell, that is, mutations could be expressed only after cell division. Since there were two cells at the tip of the hair and occasionally a third intercalary cell which were meristematic, the maximum number of cells per flower in which a mutation could occur and be expressed was 3×55 (hairs per filament) $\times$ 6 (filaments per flower) = 990. All the hairs do not develop simultaneously and the number of potentially mutant cells is low initially, increasing to a maximum of about 990, and then decreasing again. The pattern of mutation production was similar.

Eight inflorescences were exposed in air in the muon beam for each of the following periods of time—2, 4, 6, 8 and 10 h. Dosimetry was complicated by the fact that the beam was non-uniform over its entire area (a circle 12 in. diam.). To obtain accurate measurements individual phosphate glass dosimeters (rods 1 mm diam., 5 mm long)[6] and in some instances lithium fluoride thermal luminescent dosimeters also[7] were attached to each inflorescence. These dosimeters were calibrated in the muon beam against a Rossi type *W* tissue equivalent ionization chamber[8]. The small dosimeters had an accuracy of ± 5 per cent within the dose range used here. Muon doses for the 40 inflorescences (8 inflorescences, 5 exposure times) varied from 12 to 101 rads, and the dose rate fluctuated between 7·3 and 13·5 rads/h, the dose being administered as explained earlier in pulsed beams at 2·5-sec intervals.

Table 1. ESTIMATED RELATIVE BIOLOGICAL EFFICIENCY (RBE) VALUES FOR μ^- MESONS AND γ-RAYS

Day	α-coefficient (μ meson)	α-coefficient (γ)	RBE
1	0·14785	0·20128	0·73
2	0·17038	0·23147	0·74
3	0·17723	0·21877	0·81
4	0·14300	0·16000	0·89
		Mean RBE	0·79

As a standard for the muon treatments, inflorescences were exposed in air at a dose rate of 7·5 rads/h to four doses of cobalt-60 γ-rays: 30, 48·7, 71·2 and 120 rads (measured with the same tissue equivalent ionization chamber). Eight inflorescences per treatment were also used for the γ exposures. An estimate of the spontaneous mutation rate was obtained by scoring 72 unirradiated flowers.

Virtually no lethality was induced within these dose ranges, and there was no opportunity for cell selection or an elimination of mutant cells. Mutations were scored in the staminal hairs of flowers emerging on four successive days and the data relating yield per flower, to dose in rads, fitted to linear, $y = k + \alpha D$, and quadratic, $y = k + \alpha D + \beta D^2$, regressions. In all instances linear regressions better fitted the data, and the linear (α) coefficients for the muon and γ exposures for each of the four days are given in Table 1. The relative biological efficiency of muons: γ is given by the ratio of the α coefficients, and has a mean value for all days of 0·79. This value is essentially in agreement with what would have been predicted from a knowledge of the linear energy transfer characteristics of the μ mesons, and appears to be significantly lower than 1, though this would be difficult to prove conclusively with the present experimental system and methods of dosimetry.

An approximate estimate of the absolute 'mutation' rate per cell may be obtained from the data of that day when the number of meristematic cells per flower is at a maximum, that is, about 1,000. For the chronic γ exposures, the yield per flower for that day was 0·03527 + 0·23147 = 0·26674/rad, and the approximate rate per cell per rad was therefore $2·7 \times 10^{-4}$.

Cæsium-137 Body Burden in Persons chosen at Random from Selected Areas in Norway

The global distribution of fall-out has not been uniform: due to nuclear weapon tests by far the largest fraction has been deposited on the northern hemisphere. These circumstances are partly a result of the geographical positions of the test sites; partly a result of meteorological conditions.

The amount of fall-out deposited is normally a function of rainfall. Local areas with high precipitation on the northern hemisphere have thus shown by far the largest contamination. This is the case in certain districts on the west coast of Norway having a yearly precipitation ranging up to 3,500 mm.

As a result of the fall-out, fission products have gained access to soil and vegetation, human food and consequently also to man himself.

One of the radionuclides in the fall-out which is of special interest in this connexion is cæsium-137 due to its long physical half-life, its large fission yield and its chemical similarity to potassium which is a very important body constituent.

In order to measure radioactivity in the human body, installation of a whole-body counter at Norsk Hydro's Institute for Cancer Research was begun in February 1962.

Early in the construction period while Norway was still covered by snow and hence the cattle fed on hay gathered before the nuclear tests were resumed in 1961, we started a systematic collection of milk samples from all Norwegian dairies. It was felt justified to assume that the amount of activity in the milk at that time would be down to a minimum of long-lived radionuclides, so that the milk survey would give an approximately stabilized picture of the geographical distribution of the fall-out. Since the milk was measured in a γ-spectrograph, cæsium-137 was the natural radionuclide to use as an indicator.

It has previously been shown that the cæsium-137 body-burden in man[1] to a large degree depends on milk consumption. It could thus be expected that the concentration of cæsium-137 in milk to some extent could be regarded as an indicator of cæsium-137-levels in people from the various districts.

In Table 1 the results of the milk survey are presented. The figures given are mean values for the cæsium-137 contents in regions I, II, III and IV, representing the eastern, western, middle and northern parts of Norway as indicated on the map. Also maximum and minimum values found in single samples from dairies in these regions are given.

Table 1

Region	No. of samples	^{137}Cs pc./l.* min.	max.	mean.	Production per month ($\times 10^6$ l.)	Total amount ^{137}Cs μc. per month	Population ($\times 10^6$)
I	96	0	120	20	35	737	1·75
II	108	5	505	115	30	3,510	1·08
III	42	5	175	45	14	641	0·33
IV	26	55	675	230	8	1,838	0·44

* 1 pc. = 1 μμc. = 10^{-12} c.

As can be seen from Table 1, the contamination in milk from regions II and IV is relatively high. From a body-burden point of view, both regions are thus of considerable interest. However, region IV is far more inconvenient than region II with regard to transport of people to Oslo for total body-burden measurements. We therefore decided to undertake a more detailed examination of the conditions inside this district. As a result of these investigations we directed our attention on Masfjorden, a small community near the coast, some miles north of Bergen. Masfjorden is one of the districts having the highest yearly precipitation in Norway.

A more detailed study of the milk from Masfjorden showed that its cæsium-137 content showed a first decided increase in June, rising all summer to a maximum of about 1,600 pc./l. by the end of September. Then the value showed a rapid decline.

As a first part of our cæsium-137 body-burden examination of people from the western part of Norway, we thought it would be of particular interest to start our investigations with a group from this district. A statistically selected assembly of 11 persons willing to take part in this programme travelled in February 1963 to Oslo to have their body-burden measured in the whole-body counter. Another group of 10 persons from the city of

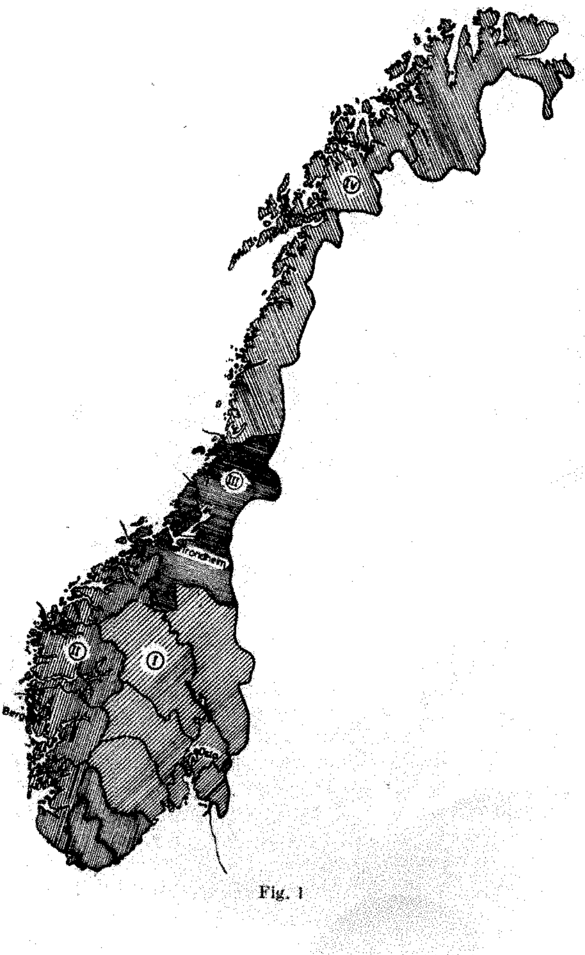

Fig. 1

Table 2

Locality	No of individuals	Body-burden nc ^{137}Cs min	max	mean	^{137}Cs/K pc /g min	max	mean
Masfjorden	11	27 6	162 5	91 8	211	1,395	784
Bergen	10	20 0	75 6	44 2	182	497	332

Bergen were measured at the same time The results of these measurements are shown in Table 2

It is interesting to note the great differences in the body-burdens measured in these two groups, despite the fact that their homes are not more than 30 miles apart This is probably a result of the fact that food consumed in Bergen is a mixture of products from a variety of places, many of them being localized to inland districts, whereas food consumed in Masfjorden to a large extent is of local origin

Two of the individuals from Masfjorden having nearly the same body-burden (162 5 nc and 153 0 nc) were of special interest, due to their highly different milk intake One of them was a heavy milk consumer (2 0 l /day) while the other stated that her milk consumption was only 0 25 l /day

There is thus no evidence of a direct correlation between milk consumption and the cæsium-137 body-burden, either for the people from Masfjorden or for those from Bergen It is therefore to be expected that even other products are of importance

BIOLOGY

Reduction of Radiation Mortality through Magnetic Pre-treatment

THE effect of whole body irradiation on rodents with lethal doses of X-rays or γ-rays is one of the most widely investigated phenomena Mortality depends on the total dose, intensity at which the dose is delivered, strain, sex and age of the animal Both serial histological examination and direct counts demonstrate the rapid loss of nucleated cells from the bone marrow The animals' failure to replenish the granulocytes, platelets and erythrocytes from the circulating blood is primarily responsible for the death, as a consequence of septicæmia, hæmorrhage and anæmia

In a previous communication[1] it was shown that leukocytosis setting in after treatment of animals in magnetic fields[2] can be used to compensate partially the radiation syndrome In 17 further experiments a total of 920 mice of different age and strain were treated in homogeneous and inhomogeneous magnetic fields Various time-intervals were interposed between the termination of magnetic treatment and irradiation, also treatment after irradiation was tried In all experiments the permanent magnets, cages and dummy magnets, described elsewhere[3], were used In most instances 30 mice were treated in 10 permanent magnets for a period of 14–20 days and the same number of mice housed during the same time in ten dummy magnets After treatment all were removed for a specified number of days to standard plastic cages, whereupon all of them were exposed to irradiation with γ-rays in the Cobalt Therapy Unit of the Cook County Hospital in Chicago, Illinois The total administered dose was always 800 r , delivered at an intensity 33–100 r /min It produced in the control group a mortality of 30–100 per cent

After irradiation the animals were placed in standard plastic cages, 3 treated and 3 controls to the same cage, to compensate for possible cage effects The body weight was measured daily, the dead removed within 4 h after death, even during the night They were immediately autopsied, liver and spleen weight measured and from the general inspection of the organs the possible cause of death noted In four experiments blood samples were taken from the tail vein on several occasions after irradiation Leukocytes and erythrocytes were counted with a Coulter electronic particle counter

These investigations revealed many interesting features, but in most instances they can be considered only as preliminary results which need further confirmation However, two significant results emerged

A magnetic pre-treatment of mice in a homogeneous magnetic field of 4,200 œrsteds strength and less than 3 days of delay between the termination of treatment and irradiation decreases the death rate by 24–30 per cent The results of five such experiments, performed under the described conditions, are shown in Table 1 The difference in mortality rate is significant on a probability-level (*P L*) of 1 800

Table 1

Mortality (%) Magnet	Dummy	Relative mortality difference (%)
70 0	90 4	−22 6
66 7	100 0	−33 3
45 0	70 0	−35 7
60 0	76 7	−21 8
53 4	66 7	−19 9
		−26 7 ± 3 2

t, 8 3, *n*, 4, *P L* , 1 800

The leukocytosis following the magnetic treatment does not compensate the leukopenia caused through irradiation it merely diminishes it slightly For example, on the 10th day after irradiation in one experiment the leukocyte count of the treated group was 13 per cent of normal, while that of the controls was 9 per cent Nevertheless, it seems to be that even this small difference is adequate to prevent death in some cases The lowering of the death rate is most pronounced from the 7th to the 14th day after irradiation, that is, during the intestinal and bone marrow mode of the radiation syndrome This interval coincides with the time when the maximum of the leukocytosis, caused by the magnetic treatment, is observed

Treatments in inhomogeneous fields were performed at a somewhat lower field strength (3,600 œrsteds), but with a vertical gradient of 650 œrsteds/cm, produced with the help of special pole caps It corresponds to an average paramagnetic strength of 2 3 mega-œrsteds per square cm In some experiments the animals were changed daily from a north pole-up field to a south pole-up field. This is equivalent to a change of the field vector direction by 180° relative to the animal It should decrease all reversible effects caused by a homogeneous field, but the exchange leaves unaltered the direction of the vertical gradient vector relative to the animal and hence should not affect reversible paramagnetic effects

In four experiments in which the mortality of the controls was between 25 and 45 per cent, the magnetically treated animals had a higher mortality rate (relative mortality difference $+19 \pm 9$ per cent) In three experiments, with a mortality of the controls between 65 and 95 per cent, the mortality of the treated was lower (relative mortality difference $-21\ 3 \pm 6\ 5$ per cent) The lowering of the death rate was most pronounced from the 10th to the 20th day after irradiation, it covers, therefore, mainly the late mode of the radiation syndrome, a mode in which anæmia plays a major part

Treatment in inhomogeneous fields affects not only the leukocyte count, as does homogeneous fields, but also the erythrocyte count and could therefore affect irradiation anæmia But due to the simultaneous variation of two blood elements (probably also platelets), the interpretation of the mortality curve in experiments with inhomogeneous fields is too complex to be attempted at present

The experiments were supported by the Biomagnetic Research Foundation

Distribution of Cyanole and Neutral Red in the Giant Axon of the Squid

PREVIOUS work on the permeability of frog muscles[1] and giant axons of Cephalopoda[2,3] to vital dyes has shown that basic and acid dyes rapidly penetrate the cell and its intracellular content may be less or greater than in the medium, depending on the outside concentration and type of the dye For giant axons in the steady state the coefficient of distribution ($Q = \frac{C_{in}}{C_{out}}$, where C_{in} and C_{out} represent respectively intra- and extra-cellular concentration) for the acid dye (cyanole) was found to be 0 12 with the external dye concentration varying from 0 1 to 1 0 per cent (ref 3) At the same time the coefficient of distribution of the basic dye (neutral red) changed from 5 5 to 0 65 on a corresponding increase in C_{out} from 0 004 to 0 16 per cent (ref 2)

The purpose of the work recorded here was to investigate the Q values for axoplasm itself and compare them with the previously obtained values for the whole axons Therefore the content of the dye was determined both in the whole axons and pipetted axoplasm

Experiments were performed on the axons of *Loligo* sp , 200–300μ in diameter Isolated axons were soaked in cyanole or neutral red solution for 20 min As has already been shown[2], a period of 10–20 min is enough to reach equilibrium Then the axons were washed up (5–10 sec) in sea-water and blotted The amount of dye in ethanol acid extracts of axons was determined with the aid of a visual microcolorimeter For measuring the dye content in axoplasm the stained fibres were cut, axoplasm was then extracted with a micropipette and also transferred to the ethanol acid mixture The amount of dye was calculated per unit of the fibre or axoplasm volume.

The results obtained are given in Table 1

Table 1

Dye	Concentration in the axon (C_{in}) (mg %)	Concentration in the axoplasm (C_{ap}) (mg %)	$\frac{C_{in}}{C_{ap}}$	$\frac{C_{ap}}{C_{out}}$
1% Cyanole	120 ± 5	82 ± 16	1 46	0 082
0 01% Neutral red	63 ± 5	35 ± 5	1 80	3 5

As can be seen, an increase as well as a decrease in the bulk dye concentration in axons compared with the medium depends on the concentration of dye in the axoplasm In accordance with the previous studies[1–3], the observed distribution of dyes can be considered as a result of two factors (1) decreased solubility of protoplasm for the substances with the size of molecules as big as that of dyes, (2) adsorption or chemical binding of dyes by protoplasmic components Hence the total content of the dye in axoplasm may be expressed with the formula given by Troshin[1] $C_{in} = K \times C_{out} + A$, where K is the solubility coefficient of the dye in protoplasm as compared with the medium, thus $K \times C_{out}$ gives the dissolved portion of the dye, A is adsorbed or chemically bound dye per unit volume

The analysis of cyanole distribution shows[3] that, by varying C_{out}, A is practically equal to 0, whereas for neutral red the bound dye fraction is big enough[2] This is also confirmed by special experiments made to investigate the efflux of dyes from axons When cyanole-stained axon is put in sea-water, the dye leaves the fibre very soon, and the axon becomes completely colourless within 5 min Similar experiments with neutral red show that the colour is retained for a much longer time Thus, after 30 min soaking in sea-water, the neutral red concentration in axoplasm was still 14 ± 4 mg per cent, that is, 40 per cent of the dye still remained in the axon The same slow efflux of cyanole was observed only in killed or damaged axons

The experiments show that in the case of cyanole the dissolved fraction of the dye gave only $0\ 12 \times C_{out}$ while for neutral red[2] $K = 0\ 25$

The values obtained for K, considerably less than unity, probably indicate that not the whole protoplasmic water is available for the substances with the size of molecules more than 3 Å In any event, a steady-state distribution of dyes with the Q value less than unity cannot be explained by the Donnan effect[2,3], analogous Q values were obtained for the distribution of non-electrolytes in muscles[1,4,5]

Thus we can conclude that the difference in the steady-state concentration of the dye in axon as compared with medium (decrease as well as increase) may be explained by the specific properties of axoplasm, and for this explanation no membrane pump hypothesis is needed

Dispersal Rates of Several Ungulates introduced into New Zealand

BETWEEN 1851 and 1923 several species of ungulates were introduced into New Zealand During this period there were also many liberations into unstocked areas of game animals taken from recently established populations Dates and localities of liberations have been summarized[1,2] and the present or recent distributions of most species have been published[2–5]

Table 1 gives mean rates of dispersal over periods exceeding 50 years, taken from populations that were continuously expanding their ranges over these periods The rate is measured as the distance between the point of liberation and the farthest known breeding colony, divided by the number of years that have elapsed

Table 1 RATES OF DISPERSAL

Species	Locality	Miles a year
Chamois (*Rupicapra rupicapra*)	South Island	5 4
Thar (*Hemitragus jemlaicus*)	South Island	1 1
Red deer (*Cervus elaphus*)	Nelson	1 0
	Fiordland	1 0
Sika deer (*Cervus nippon*)	North Island	1 0
Whitetail deer (*Odocoileus virginianus*)	Stewart Island	0 6
Fallow deer (*Dama dama*)	Wanganui	0 5
Rusa deer (*Rusa timorensis*)	North Island[9]	0 5
Sambar deer (*Rusa unicolor*)	Manawatu	0 4
Wapiti (*Cervus canadensis*)	Fiordland	0 4

There have been more than 100 liberations of red deer[6] and the populations developed from these have coalesced so that the pattern of dispersal is now completely obscured But the distributions had been roughly mapped before this occurred[7], and a rate of dispersal can be calculated for the Nelson herd between 1851 and 1924 This is probably one of the few red deer herds the distribution of which was not strongly modified by secondary liberations near its periphery The rate of spread in Fiordland has been published[6], it was calculated from evidence derived from the vegetation and from hunters' reports.

No research has been undertaken to determine whether dispersal in New Zealand is largely independent of a population's density, or whether the rate fluctuates with changes in the population and its environment. Present work on sika deer, chamois, and thar should eventually answer this question.

Significance of Allopreening in the Red Avadavat and its Development in Other Birds

ALLOPREENING, that is, the habit of preening a neighbouring individual's feathers, is characteristic of many gregarious species of birds. Recent work on the Estrildine finch, the red avadavat (*Amandava amandava*), has shown that the amount of mutual grooming does not vary with the presence of peripheral dirt on the regions to which most of the allopreening is restricted, that is, the head. It thus seems likely that allopreening is more than simple co-operation in toilet behaviour between individuals which cannot effectively clean or arrange the feathers on their own heads as suggested by Morris[1].

Preening is a subsidiary resting response, and in species in which the individuals are forced together, nibbling each others' feathers is a common activity, as in guillemots (*Uria aalge*) or young chickens (*Gallus gallus*). Birds seem to possess an innate response to feathers as primates have to fur[2]. Ritualized allopreening invitation postures are found in many highly gregarious 'contact' species and in 'contact' species where the members of a pair are closely associated throughout the year. In *A. amandava* there is specialized behaviour for eliciting grooming by a neighbour in the form of mandibulation nudging, and head proffering.

When two red avadavats which are unfamiliar with each other approach and clump, the clumper is invariably pecked first, but in response to this, an allopreening invitation posture is taken up which results in an amelioration of the aggressive behaviour and the assumption of mutual preening[3]. Between strangers, then, allopreening serves to reduce aggression between the clumping individuals, but when they are fully familiar and their relationship is characterized by an absence of fear and aggression, allopreening serves to strengthen the social bonds between the birds, as suggested for social grooming in primates[2].

The allopreening invitation posture is rarely used as a simple appeasement gesture in the face of an all-out attack in the manner suggested by Morris[1], but is only given if the submissive individual is in strong conflict between approaching and fleeing, and is usually at the same time sexually attracted to the attacker. Otherwise, the immediate response to attack is flight.

Fertilization of Hamster Eggs *in vitro*

FERTILIZATION of rabbit eggs *in vitro* has been reported by many workers in recent years and Austin[1] concluded that "success seems most likely to have been attained by Smith (1951), Dauzier *et al.* (1954), Dauzier and Thibault (1959), Thibault *et al.* (1954), Thibault and Dauzier (1960), Moricard (1954 *a*, *b*), and, particularly, Chang (1959)". So far as is known, no authentic successful experiments to fertilize rodent eggs *in vitro* have been reported[1-4]. This communication describes a repeatable technique to fertilize the eggs of the golden hamster (*Mesocricetus auratus*) *in vitro*, and the results obtained by this technique.

Female hamsters that came into heat between 6 p.m. and 9 p.m. were killed at 6-7 a.m. the next morning. Since most of the females ovulate about 8 h after the onset of heat[5], these females were considered to have ovulated at about 2-5 a.m. Thus, the eggs were considered to be about 1-5 h after ovulation at the time of recovery. The oviducts of an animal were isolated, placed on a piece of filter paper, and most of the blood adhering to the oviducts was rubbed off. The oviducts were then put on the centre of a watch glass (4 cm in diameter) and were immediately covered with warm (30°-37° C) mineral oil (Squibb). Under a dissecting microscope and on a warm stage, the distended portion of the ampulla was incised with needles and the eggs in cumulus oophorus were pressed out with some of the tubal fluid. The oviducts were discarded and blood and tissue debris, if any remained in the watch glass, were removed with a pipette. A small drop of sperm suspension, about 1-3 times the amount of the egg clot, was then added through the needle (25-27 gauge) of a tuberculin syringe to the eggs that were under the mineral oil. The eggs and the sperm suspension were thoroughly mixed with a needle. The watch glass was then kept in an incubator at 36° C.

The sperm samples were collected either from the uterus of a female mated with proved male about 0.5 h, or 4-5 h, previously, or from the caudal epididymis of a fertile male. Usually, a drop of dense sperm mass was put on the centre of a watch glass (6 cm in diameter) and covered with 2-4 ml. of a solution containing 10 parts of tissue culture medium, '*TC* 199' (Difco Laboratories), 3 parts of M/8 glycine, and 100 units/ml. of penicillin *G*. Under the microscope, the dispersion of sperms could be seen, the motility assessed to choose the best sample, and a suspension of desired concentration of sperms taken through the needle into a tuberculin syringe.

All the glassware and instruments were washed with double distilled water, sterilized, and kept at 30°-37° C before and during use. Aseptic precautions were maintained during the whole operation.

Seven to ten hours after insemination, the eggs in the watch glass were transferred to a slide, compressed gently between a coverslip and the slide, and examined under a phase-contrast microscope for evidence of fertilization. The eggs were considered to be fertilized only when enlarged sperm heads or male pronuclei were found in the vitellus. Particular attention was directed to the tail of fertilizing sperm in or around the vitellus (Fig. 1). Occasionally, one or more sperms with intact (unswollen) heads were found in the perivitelline space or on the surface of the vitellus. Such sperms were recorded as supplementary sperms.

When 171 eggs from 21 females were inseminated with sperms recovered from the uterus of females mated 4-5 h previously, 113 (66 per cent) were fertilized. Of these fertilized eggs, 76 (67 per cent) were monospermic and 37 (33 per cent) were polyspermic (24 dispermic, 7 trispermic, 5 tetraspermic, and 1 pentospermic, as shown by the number of pronuclei and that of sperm tails in or around the vitellus). Seventeen monospermic eggs and 14 polyspermic eggs had 1-5 supplementary sperms.

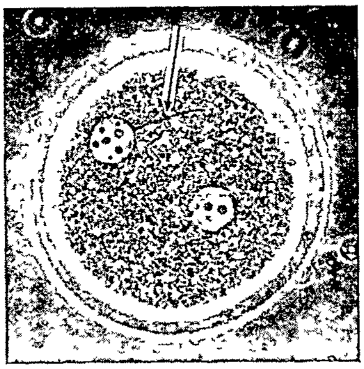

Fig. 1. A hamster egg fertilized *in vitro*. Phase-contrast, arrow indicates the tail of the fertilizing sperm

Supplementary sperms (1–3) were also found in 7 unfertilized eggs.

When 116 eggs from 15 females were inseminated with sperms recovered from the uterus of females mated 0.5 h previously, 36 eggs (31 per cent) were fertilized. Of these 36 eggs, 31 (86 per cent) were monospermic and 5 (14 per cent) were polyspermic (4 dispermic and 1 trispermic). Supplementary sperms (1–3) were observed in 6 monospermic, 4 polyspermic, and 2 unfertilized eggs.

Insemination of 152 eggs from 17 females with epididymal sperms resulted in the fertilization of 26 eggs (17 per cent). Of these 26 fertilized eggs, 20 (77 per cent) were monospermic and 6 (23 per cent) were polyspermic (5 dispermic and 1 tetraspermic). Supplementary sperms (1–5) were found in 5 monospermic, 4 polyspermic, and 3 unfertilized eggs.

These results clearly show that sperms that have been in the female tract for a longer period (4–5 h) can fertilize a higher proportion of eggs (66 per cent) than sperms in the female tract for a short period (31 per cent) and those recovered from the epididymis (17 per cent). This indicates the possibility that capacitation[6–8] of hamster sperm may have occurred in the female tract.

When the hamster eggs are normally fertilized *in vivo*, the zona reaction[9] to block the entry of the second sperm is very strong and polyspermy is rare[10,11]. Under the present condition, on the contrary, the proportion of polyspermic eggs was extremely high (14–33 per cent). Whether this is due to a high concentration of sperm at insemination, fast ageing of eggs *in vitro* as has been shown in the polyspermy of aged eggs *in vivo*[12], or other factors, is still not known at present. Except in a few cases where degenerative changes were observed, most of the eggs fertilized by a single sperm appeared to be quite normal at the pronuclear stage. Whether they can develop further in culture or can develop into young by transplantation into recipient animals is under investigation.

This work was supported in part by grants from U.S. Public Health Service, *GM*10529-01, and *GM*-08167-03, and by a grant from the Population Council.

Distribution of Nuclei in a Heterocaryon of *Penicillium expansum*

THE overall frequency of diploid nuclei in a balanced heterocaryon has been estimated by Pontecorvo[1] to be of the order of one in 10^6 or 10^7. Thus, a colony containing 1×10^9 conidia would include 100–1,000 diploid conidia.

In experiments with *Penicillium expansum*, I established a heterocaryon between M54, a brown strain requiring riboflavin and pyridoxine (br_3 ri_1 pyr_1), and M67, a white acriflavine-resistant strain requiring biotin and nicotinic acid (w_3 acr_1 bi_1 nic_2)[2]. In attempts to recover diploids from this heterocaryon, 317 million conidia were plated out without success. In contrast, in a similar experiment between strains M53 (ri_1 bi_4 w_2) and M54 (ri_1 pyr_1 br_3), 179 diploids were recovered from a plating involving only 19 million conidia.

This can be explained if only one or few nuclei are responsible for initiating the entire conidiophore in *Penicillium*. In such a situation, all or most of the conidiophores would be homocaryotic, and in a population involving 1×10^9 conidia the expected 100–1,000 diploids would be in a single head. The experimental result would be the recovery of either a large number of diploid nuclei or none at all. To verify this in *P. expansum*, the conidiophores of a heterocaryon M54+M67 were processed and classified as either homocaryotic or heterocaryotic.

The conidiophores are quite small and closely packed, and it was not possible to classify heads visually based on colour of the conidia. Whole conidiophores were, therefore, picked off with a needle of drawn glass and the spores streaked on complete medium. Following sporulation, the genetic nature of the conidiophores was assessed on the basis of colony colour. Analysis of 463 heads in this manner gave the following results: brown, 173; white, 227, variegated, 63. Thus, 86 per cent of heads in the experimental heterocaryon were homocaryotic brown or white and only 14 per cent were heterocaryotic, giving rise to variegated colonies.

A nuclear ratio in the heterocaryon significantly removed from 1 : 1 could influence considerably the number of homocaryotic heads of one or other type. The nuclear ratio in the heterocaryon was therefore estimated by making a suspension of a 100 million conidia and, by dilution series, arriving at a concentration of approximately 100 conidia per ml. This suspension was plated on complete medium at the rate of 1 ml. per plate and the resulting colonies classified according to colour. Analysis of colonies gave 385 white and 362 brown. In the particular heterocaryon being investigated, the nuclear ratio as based on conidium analysis closely approximated 1 : 1.

In the heterocaryon studied only one nucleus, or a few like nuclei, segregated into the large majority of the young conidiophores. Such nuclei were then removed from contention so far as diploidization was concerned and a population of 1×10^9 conidia loses its numerical significance. In effect, we are sampling a million significant nuclei segregating into the conidiophores and thence being multiplied by a factor of approximately a thousand times by the conidiophore apparatus. If the frequency of diploid nuclei in the somatic hyphæ is one in 10^6, and we presume for argument that all conidiophores are homocaryotic, then we would expect on the average only one diploid conidiophore in a stand of one million conidiophores, that is, 1×10^9 conidia. If we consider further that the frequency of diploid nuclei in the vegetative hyphæ is one in 10^7, and the likely possibility that the distribution of diploid nuclei in somatic hyphæ is non-random, then the problem is compounded. To some extent, the situation is compensated for by the fact that not all conidiophores are homocaryotic, but it can be appreciated, nevertheless, that a population of 1×10^9 conidia may contain no diploids at all

In connexion with the study of parasexual phenomena in fungi imperfecti, then, it would be an advantage to know if the conidium bearing fructification is derived from one nucleus or from many nuclei In the latter situation diploidization may still occur in the reproductive parts, resulting in a better distribution of diploids

In an examination of *Colletotrichum lagenarium*, Dutta and Garber[3] failed to recover a diploid from platings involving 100 million conidia from several heterocaryons In *Colletotrichum* each acervulus may produce 10,000–100,000 conidia If an acervulus has its origin in one or few nuclei, many acervuli will be homocaryotic and a sample of 100 million too small perhaps to locate a diploid Even in a heterocaryotic acervulus, a mosaic pattern of development might permit considerable multiplication of nuclei without the possibility of diploidization

As a corollary it might be stated that abundant sporulation is not in itself an advantage in the study of genetics of imperfect fungi, and even when a fungus has a relatively low sporulation capacity (1/1,000 that of *Penicillium*), it may still be studied adequately with respect to parasexual phenomena

Rapid Changes in Transpiration in Plants

IN the recent discussion in *Nature* under this heading[1–3], Rufelt[1,3] has adopted Ivanoff's[4] hypothesis that the transient increase in transpiration rate observed when a leaf is detached in air is caused "by a sudden release of the water stress in the conducting elements, which means that it is caused by an increase in the water supply to the leaf"[1] He has further supposed that the increase in transpiration obtained after bathing the roots of intact plants with mannitol solution[5], or 1 M sodium chloride[1], is also due to the release of water stress in the plant, making the subsidiary hypothesis that the mannitol or sodium chloride causes an increase in the water permeability of the roots[1]. He concludes that this last effect is peculiar to the roots[1], and since he writes of "the permeability barrier in the root"[3] he must postulate that the transpiration stream here passes through the cells, though in the whole of the rest of the plant he supposes it to move in the cell walls only, except when it is in the xylem He would appear to have obtained no data for the behaviour of the stomata in his experiments; his discussion of the supposed absence of 'mechanical effects' and the different permeabilities of guard cells and epidermal cells therefore seems too great an extrapolation from his results—transpiration rate can only be taken as a measure of stomatal diffusive conductance when there is a constant potential difference across the stomata

Heath[2] supposed that the observed increase in transpiration rate, in the experiment with sodium chloride, was due to 'passive' stomatal opening (Rufelt's 'mechanical effect') brought about by rapid wilting He suggested that the 'Ivanoff effect' must be mainly due to the same cause and that the contribution of the release of tension in the xylem sap must be very small

We have investigated the effects, on stomatal movement, transpiration rate and leaf water content of wheat plants, of bathing the roots with 1 M sodium chloride (Table 1). Potted plants of wheat var Thatcher growing in John Innes No 1 compost were used Stomatal movement was followed with a 'Wheatstone bridge porometer'[6], and Log_{10} leaf resistance to viscous air flow (in 'Gregory and Pearse units'[6]) is tabulated, transpiration rates were followed with the 'differential transpiration porometer'[7] for the same place on the leaf and the data are tabulated as mm galvanometer deflexion Leaf water contents were estimated from six leaf blades, similar to that used for the porometers, for each pot on each of three occasions—the first when stomatal apertures and transpiration were steady, the second when both had increased as a result of sodium chloride treatment and the third when they had decreased again Stomatal opening began within 20–60 sec of flooding the soil with 1 M sodium chloride and a rise of transpiration showed in the next reading of the transpiration porometer (2–4 min) The data are strongly suggestive of stomatal control of transpiration and show a fall in leaf turgor within a few minutes of applying the sodium chloride

Table 1 EFFECTS OF TREATMENT OF ROOT SYSTEMS OF WHEAT PLANTS WITH 1 M SODIUM CHLORIDE

Pot No		Time* (min from supply of NaCl to roots)	Stomata $\text{Log}_{10} R$	Transpiration deflexion (mm)	Change of transpiration Increases and decreases in deflexion (mm)	Leaf water content (% of dry wt (6 leaf blades))	Relative turgor

4	Young leaf	+30	$\bar{4}$ 82	80	−10	525	85 0
5	Young leaf	+30	$\bar{4}$ 64	100	0	510	89 5

* These are the actual times for the $\text{Log}_{10} R$ values, the corresponding values for transpiration and for leaf water content were obtained slightly earlier

On Rufelt's hypothesis of "an increase in the water supply to the leaf", the leaf water content must increase even if the water travels entirely in the cell walls, not only will the cell walls themselves hold more water but also as they will hold it less strongly (increased water potential) more of it will pass into the vacuoles It is not very clear whether Rufelt considers that the increase in transpiration is entirely due to this increase of water potential, in which case leaf turgor must remain higher so long as the higher rate of transpiration persists, or whether he supposes that stomatal opening caused by increased guard cell turgor also contributes In the latter case, leaf turgor could fall again before the transpiration rate The hypothesis put forward by Heath demands in this type of experiment a continuously falling leaf water content and would be disproved by an observed increase Both our data here and those in Rufelt's Table 1 (ref 1) are consistent with Heath's hypothesis We suggest that Dr Rufelt should attempt to detect an increase

We have also carried out a series of experiments with detached leaves of *Xanthium pennsylvanicum*, kept first in water and then transferred to mannitol solutions Stomatal behaviour and transpiration rates were followed as in the wheat experiments (Table 2)

Stomatal aperture and transpiration rate increased together, within a few minutes of applying the mannitol solutions and more rapidly with the higher concentrations Here there can have been no release of tension, as in the 'Ivanoff effect', nor were there any roots the permeability of which might have been affected An effect on the water permeability of the leaf cells bordering the xylem could be postulated but this would not accord with the suggestion that the water travels in the cell walls We prefer the view that such cells lost turgor owing to the osmotic pressure of the mannitol solution in the xylem, that this

Table 2 EFFECTS OF SUBSTITUTING MANNITOL SOLUTIONS FOR THE WATER BATHING THE PETIOLES OF DETACHED LEAVES OF *Xanthium pennsylvanicum*

Leaf No	Time (min from mannitol application)	Mannitol concentration (M)	Stomata (Log$_{10}$ R)	Transpiration deflexion (mm)

8	+5	0 05	$\bar{4}$ 68	130

resulted in a change in the suction pressure gradient to the epidermal cells and the loss of turgor of the latter caused 'passive' opening of the stomata, resulting in increased transpiration

In a third type of experiment we have observed the stomatal changes that follow the cutting of the stem of a *Xanthium* plant in air ('Ivanoff effect') Within 2–5 sec of excision a minute movement of the meniscus in the Wheatstone bridge porometer (observed with a lens or a reading microscope) indicates a very small closing movement of the stomata This we interpret as the 'passive' closure due to the release of tension in the xylem sap There is then a delay of a further 15 sec, after which the usual opening movement begins We suggest that this delay is the time necessary for the water in the xylem to be used up in transpiration and the leaf water content to begin to fall Quantitative estimates of the amounts of water involved are of course highly desirable and we hope to attempt these in the future

This work was carried out while one of us (H M) held a University of Reading visiting fellowship

FIRST, I would like to correct a vagueness in my contributions to this discussion I certainly think that the changes in transpiration are caused by stomatal movements I think this is very evident from an earlier paper of mine[1] Certainly I have myself no experimental proof in my papers hitherto published but a flood of evidence can be found in the literature[2–6] and theoretical considerations point in the same direction[7] Secondly, I do not agree with the authors when they assume that I postulate that the transpiration stream passes through the cells in the root because I postulate a permeability barrier In earlier experiments[1] the root permeability and cell permeability were found to be probably not identical Where the permeability barrier is localized is still a matter for discussion[8]

Thirdly, the three series of experiments published do not disprove either the hypothesis of Ivanoff or my interpretations The main point is that the stomata are thought to be influenced by the water potential of the cell wall and not by the water potential of the whole leaf In short-term experiments these may differ Consequently, changes in water content of the total leaf such as those obtained by Heath and Meidner in the first series of experiments are not illustrative of the changes determining the stomatal movements The increase which Heath and Meidner suggest that I should try to detect cannot be shown in determinations of water contents of leaves One possibility would be to demonstrate it as an increase in water transport upwards in a plant and as such it has in fact been shown by Allerup[9–11] It might be added that the reason why I have assumed that the easily movable water is localized in the cell walls is that this has been suggested by Strugger and others[12,13]

The results of the second series of experiments are very similar to those obtained by Haines[14] and Humphries[15] These authors interpreted the increases in transpiration as caused by changes in water permeability However, one circumstance makes the present experiments difficult to interpret An osmotic suction from the mannitol solution requires a semipermeable structure If there is one, its permeability can be changed

The third series of experiments is a recapitulation of those of Allerup[10] which he has interpreted according to Ivanoff's hypothesis

It is evident that most of the experiments can be interpreted according to both the hypotheses Nevertheless, I still cannot find that the experiments described in my communication[16] by Figs 1, 2 and 3 have been explained by Heath's hypothesis However, I think we all make extrapolations from our results and would like to postpone further discussions as to who is right and who is wrong until some more pertinent experiments have been performed

Effect of Chloramphenicol on the Uptake of Salts and Water by Intact Castor Oil Plants

THE antibiotic chloramphenicol has been found to inhibit accumulation of salt by slices of red beet tissue and carrot tissue without significantly affecting respiration[1]. This supports the hypothesis that the mechanism of salt uptake is closely related to protein synthesis put forward by Steward and Millar[2], as chloramphenicol is a specific inhibitor of protein synthesis

Experiments have been carried out to determine the effect of chloramphenicol on the salt uptake of intact plants Castor oil plants (*Ricinus communis*) were grown singly in aerated culture solution in 500 ml polythene growth vessels The culture solution was similar to that described by Stout and Arnon[3] except that it was diluted ten times and iron was present as chelate The concentrations of potassium, calcium and nitrate were 0 79 mM, 0 50 mM and 0 38 mM respectively. The solution was renewed daily during the growth of the plants In each experiment the uptake of the foregoing three ions and water by a single six-week old plant was followed first from complete culture solution, then from culture solution to which chloramphenicol (2 g/l) had been added and finally again from culture solution alone Each experiment was of 12-h duration and the medium was drained from the vessel for analysis and replaced with a fresh volume (250 ml) after a given period, usually 1 h. Uptake of water was determined from the decrease in volume and uptake of potassium, calcium and nitrate from the decrease in the amounts of these ions in the medium over the given period The cations were determined with an EEL flame photometer and nitrate colorimetrically by the phenoldisulphonic acid method The temperature was kept constant at 25° C and a light intensity of about 750 ft - candles was given throughout each experiment

Table 1 EFFECT OF CHLORAMPHENICOL ON THE UPTAKE OF POTASSIUM, CALCIUM, NITRATE (μg equiv /h) AND WATER (g/h) BY TWO INTACT *Ricinus communis* PLANTS AT 25° C

Time (h)	Medium	Plant 1 K	Plant 1 Ca	Plant 1 NO_3	Plant 1 Water	Plant 2 K	Plant 2 Ca	Plant 2 NO_3	Plant 2 Water
1	Culture	45	30	68	10	65	4	139	6
2	Solution	59	42	117	10	85	18	139	6
3		54	42	117	10	80	28	146	6
4	Culture	22	18	79	9	21	10	48	6
5	Solution	−8	20	78	10	−3	2	−13	6
6	+ Chloramphenicol 2 g/l	−6	26	32	10	−5	4	40	8
7		1	44	46	10	2	10	93	6
8	Culture	16	40	4	10	35	12	101	5
9	Solution	24	38	99	9	45	20	104	5
11		42	34	56	7	—	—	—	—
12		25	48	67	8	46	22	82	5

The results from two plants are shown in Table 1 Chloramphenicol had a marked effect on the uptake of salt but the uptake of water was unaffected In both experiments uptake of potassium was stopped completely with chloramphenicol around the roots for 3 h. Uptake of calcium and nitrate was partially reduced for plant 1 and stopped completely for plant 2 These results, therefore, support those obtained with disks and indicate that uptake of salt in the intact root is closely related to protein metabolism There was a recovery in uptake of salt on the removal of chloramphenicol from the medium in all cases although the initial levels were not always regained, probably because of the evening fall off in uptake through diurnal rhythm These experiments were started at 9 a m and finished at 9 p m , and uptake of salt is at its maximum at mid-day and minimum at mid-night in these plants In work to be published shortly[4], it has been shown that most of, and sometimes all, the potassium taken up by these plants is transferred to the vessels and so it appears that the mechanism of salt transport across the root is, like the accumulation of salt by the individual cell, affected by chloramphenicol The complete stoppage of uptake of salt by chloramphenicol leaving the water flux unaffected strongly suggests that passive mass flow of these ions in solution direct from medium to xylem is not occurring in these plants

VETERINARY SCIENCE

Prophylactic Activity of Suramin Complexes in 'Surra' (*Trypanosoma evansi*)

SURAMIN, being acidic in reaction, forms insoluble precipitates—called suramin complexes—with other trypanocides which are basic compounds like antrycide dimethyl sulphate, 'Berenil' (di-(amidinophenyl)-triazene(-*N*-1 3)diaceturate), pentamidine, etc Such combinations have been reported to have markedly reduced toxicity and considerably enhanced prophylactic activity Williamson and Desowitz[1] reported maximum decrease of five- and three-fold in the toxicity of suramin complexes of antrycide and 'Berenil' respectively They found that suramin–antrycide complex protected cattle against *Trypanosoma vivax* and *T congolense* for at least 95-199 days at dose rates of 10–40 mg/kg of the antrycide content Williamson[2] reported that rats were protected against *T congolense* for 53 and 11 weeks with suramin complex of antrycide (201 mg/kg) and 'Berenil' (129 mg/kg body-weight) respectively as compared with 1½ weeks, 18 weeks and <4 weeks protection afforded by suramin (62 5 mg/kg body-weight), antrycide dimethyl sulphate (7 8 mg/kg body-weight) and 'Berenil' (50 mg /kg body-weight) respectively Since then complexes of suramin have been widely experimented with in animal trypanosomiases in Africa Suramin complexes of antrycide dimethyl sulphate and 'Berenil' were prepared after Williamson[2] and tried for their prophylactic activity against *T evansi*

Rats and mice were inoculated subcutaneously with antrycide–suramin complex, prepared fresh at 50 mg/kg body-weight of the complex They were challenged in pairs with an intraperitoneal inoculum of about 2,000 trypanosomes (*T evansi*) freshly collected from a rat showing intense parasitæmia, blood of which was diluted in citrate–saline Rats received the first challenge 70 days after treatment, afterwards at fortnightly intervals up to 254th day, then at 20-day intervals until the protection broke down Mice were challenged 45 days after treatment at weekly intervals up to the 170th day and then at 20-day intervals Suramin–'Berenil' complex at 50 mg/kg body-weight was injected in mice only They were challenged in pairs on the 57th day, 77th day and on the 81st day after the protective inoculation

Along with each batch of challenge, an untreated rat and one untreated mouse were infected with the same dose of trypanosomes as used for infecting the protected animals These animals served as untreated infected controls The survivors were observed until the end of the experiment, and the batches immediately preceding those in which trypanosomes broke through were examined for at least 30 days after being infected Tail blood of the challenged and control animals was examined fresh for trypanosomes daily for the first 15 days and afterwards at 3–4 day intervals Their tails were pricked with separate pins to prevent accidental re-infections Trypanosomes appeared in the tail blood of control rats and mice within 4 days of the infection and all of them died during the next 4 days

The first break-through in the protection given by suramin–antrycide occurred in one of the two mice challenged 190 days after treatment, and in one of the two rats challenged on the 294th day of treatment The immediately preceding batch of mice and rats challenged on 170th day and 274th day respectively stayed negative At the time of break-through in mice, there were 10 treated mice in stock which were simultaneously challenged Five of them developed parasitæmia within 10 days whereas the rest of the 5 mice remained free of the parasites for 45 days after the challenge, when they were discontinued

Protection with suramin–'Berenil' complex first broke in the pair of mice challenged on the 81st day of the protective inoculation The stock of 22 treated mice were infected, 18 developed parasitæmia whereas 4 mice were yet negative for the parasites on the 48th day when the study was concluded

Suramin–antrycide complex thus conferred solid protection against *T evansi* for 274 days in rats and 170 days in mice Therefore, the protection obtained with the suramin–antrycide complex is considerably longer than that reported for either of the constituents, namely, 63 days with antrycide prosalt under challenge of 5,000 trypanosomes[3], for 82 days with antrycide methosulphate and for > 60 days with suramin under challenge with 10,000 trypanosomes[4]. Suramin–'Berenil' complex completely protected mice up to 57 days, and only one of the two mice challenged on the 77th day after treatment

The encouraging result obtained with suramin–antrycide complex in the investigation recorded here suggests further investigations with it under greater challenges, as also trial with it in large animals

Mechanism of Early Sporidesmin Intoxication in Sheep

In a recent publication[1] on the effect of sporidesmin intoxication in sheep, attention was directed to the fact, based on histopathological evidence, that enterohepatic disturbances precede biliary obstruction. Furthermore, the total liver lipids were found to be increased in the intoxicated group of animals

This report outlines a more detailed investigation (to be published elsewhere) into the nature of these liver lipids In addition, the mechanism of the characteristic lipid changes induced by sporidesmin intoxication is considered in the light of the available information

From a group of eight weaned lambs four animals received an oral dose of sporidesmin (1 mg/kg body-weight) All animals were killed two days after dosing The livers were excised immediately, sliced into strips and frozen in liquid nitrogen They were then stored at −20° C until required for analyses The total lipids were extracted by means of a modification of the Bligh and Dyer procedure[2] Eighteen lipid components were isolated from each liver lipid extract by means of a combination of DEAE, silicic acid-silicate, and silicic acid column chromatography Identification was based on reverse-phase paper chromatography, infra-red spectrometry and chemical analyses During the course of this investigation it has become evident that the liver triglyceride-levels of the intoxicated group of animals were increased about 100 per cent above the triglyceride-levels of the normal group No significant changes were found in the other liver lipid components

There is adequate evidence that the liver is the main source of circulating plasma triglycerides[3–8] Although fatty infiltration of the liver can be induced by a wide variety of toxic substances and metabolites, the lipids accumulating in the liver are predominantly triglycerides[9–13] Oral administration of hepatotoxins, such as carbon tetrachloride, also results in a rapid increase of liver triglycerides This has been interpreted as the result of a malfunction of a hepatic triglyceride secretory mechanism[14] Many hepatotoxins appear to inhibit or destroy one or more steps in the conversion and secretion of liver triglycerides to plasma lipoproteins The initial conversion of plasma non-esterified fatty acids to liver triglycerides appears to be unaffected[14,15] Whereas the liver triglyceride-levels rapidly increase as the result of the action of hepatotoxins, the plasma triglyceride-levels, in general, become markedly decreased[14] In addition, because of their slower rates of metabolic turnover, the plasma phospholipid and cholesterol-levels remain unaffected in the initial stages

It appears then that, on the basis of the present investigation and of previous work[1,16], the effect of early sporidesmin intoxication (that is, two days after dosing) on the liver resembles the effect of other hepatotoxins

Thus in the clinical picture, described by Mortimer and Taylor[17], the early first-phase symptoms of the diphasic response strongly suggest that a metabolic disturbance in the liver triglyceride secretory mechanism is one of the contributing factors The phospholipid- and cholesterol-levels remain relatively unaffected in both liver and plasma, whereas the liver triglyceride-levels increase. However, if the early pathological situation induced by sporidesmin intoxication inhibited exit of triglycerides from the liver into the plasma, as well as their exit from the plasma into the adipose tissue, a hypotriglyceridæmia might not be observed even though the hepatic secretory mechanism is inhibited or destroyed Further work is in progress to determine the mechanisms which operate during sporidesmin intoxication

Correlation between the Reaction of Horses to a Pyrogen and their Immunological Responses in Antitetanic Serum Production

In a series of observations on about 5,000 rabbits, it was found that they could be divided into 3 groups according to their low-, medium- or high-temperature reactions to intravenous injection of a standard dose of sodium nucleinate (Merck and Co Inc , U S A., sodium salts of the acids from yeasts)[1,2] In later experiments there was found to be a good correlation between the thermal reactions of individual rabbits to the pyrogen and the intensity of anaphylactic reactions, the measurement of the rise in temperature being determined during the anaphylactic reactions[3]

Similar relationships were demonstrated between the thermal reactions to the pyrogen of individual rabbits and the degree of production of lytic antibodies (anti-sheep hæmolysins)[4,5], the mean hæmolytic titres being 1 1534. 1 2957 and 1 4317 respectively for rabbits with low, medium and high temperature reactions

It is recognized that there is considerable variation in both man and other animals in respect of the readiness with which individual members of a group can be immunized[6] To our knowledge, however, there have been no reports of investigations of a possible relationship between the temperature reactions of animals to pyrogens and the readiness with which they can be immunized

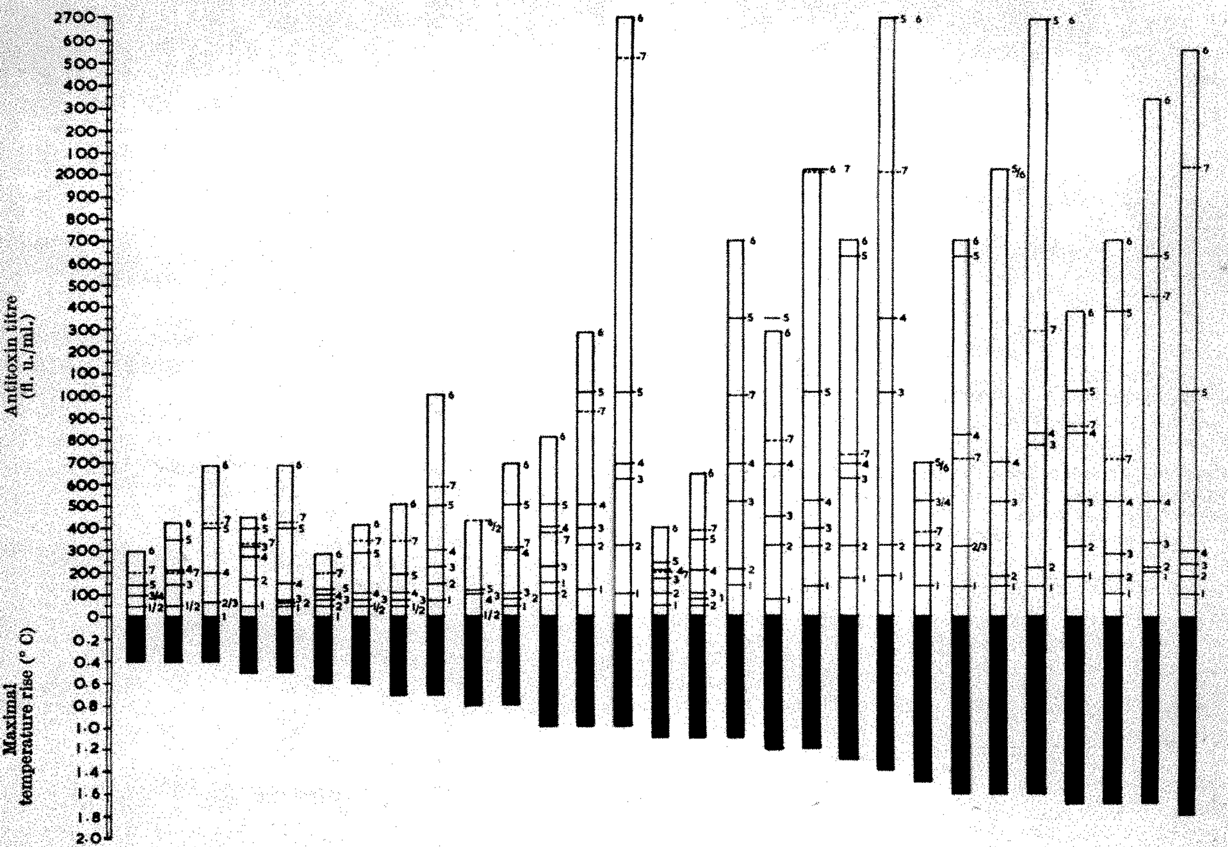

Fig. 1. Individual responses of 29 horses to pyrogen (black columns) and to antitetanic immunization (white columns). ——, 1, 2, 3, 4, 5 = titres before fourth, fifth, sixth, seventh and eighth injections; 6, that is, column height = final titre (bulk bleeding); - - -, 7, titre on second bleeding after bulk bleeding

The results presented here were obtained from investigation of the relative individual production of tetanus antitoxin by 29 horses, by examination of their sera in the course of their first series of immunizing injections, these horses having been tested for their thermal reaction to a standard dose of the pyrogen (10 mg sodium nucleinate/kg body-weight) injected intravenously as a 10 per cent solution in pyrogen-free distilled water.

The procedure adopted in the test for reaction of the horses to the pyrogen was to take the temperature of the animals on three occasions during the hour prior to the injection of the sodium nucleinate, and the figure recorded for the normal temperature was the mean of the three readings. Following the injection of the pyrogen, the temperatures of the animals were recorded every hour for 5 h and the maximal rise in temperature was taken as the figure indicating the response.

Afterwards, all 29 horses were given the series of injections for antitetanic immunization by the usual procedure adopted at the Pasteur Institute, Bucharest, which consists of a first injection of 15 ml. of anatoxin adsorbed on aluminium hydroxide followed by a series of 7 injections at 5-day intervals, starting 30 days later, with increasing doses of anatoxin and toxin adsorbed on aluminium hydroxide.

Serum samples were collected immediately before the fourth and later injections and 10 days after the last injection. The flocculation method (Ramon), with ammonium sulphate precipitated anatoxin as antigen, was used for the titration of the sera and their titre was recorded as flocculent units per ml. of serum (fl.u./ml.).

As will be seen from Fig. 1, the results show, apart from one or two exceptions in horses with medium temperature reactions, a good correlation between the thermal reaction of the individual horses to the pyrogen and the antibody-levels of their sera, and this suggests that the assessment of the reaction of horses to the pyrogen would be of value in the selection of the most suitable donors for the production of antitetanic serum.

The conclusion is supported by the statistical analysis, which was designed to establish the degree of correlation

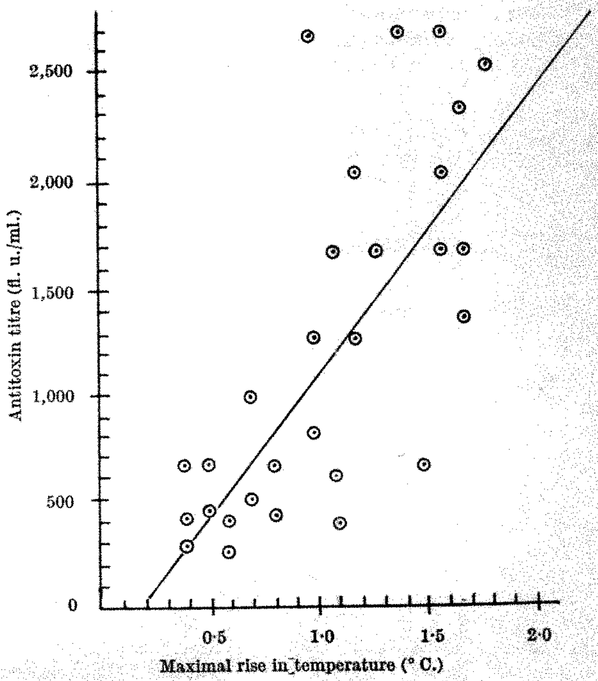

Fig. 2. Regression line indicating the correlation between the response to the pyrogen and the antitoxin titre

and best functional relationship expressing the interdependence of both responses.

The 29 response pairs were plotted on linear, semi-log and logarithmic scales and the linear was found to give the most adequate fit.

The correlation coefficient of 0·72 was highly significant (P 0·01) with a 0·05 confidence interval of 0·48–0·86. The equation for the regression line (Fig. 2) of Y (the antitoxin titre in fl.u./ml.) on X (the response to pyrogen in degrees C) is:

$$Y = 1{,}340\ X - 252$$

This equation can be used to determine the probable antitoxin titre on the basis of pyrogen response.

Further work is planned in the hope that, if similar correlations can be confirmed, it will be possible to use the thermal response, to the same or other pyrogens, as a guide for the selection of animals for the production of other therapeutic sera or for the selection of homogeneous groups of animals for, as an example, potency tests of vaccines.

ENTOMOLOGY

Some Differences in the Passage of Food through the Intestines of the Desert and Migratory Locusts

By means of an X-ray technique[1] a study of the passage of radiopaque foods through the intestine of the migratory locust, *Locusta migratoria migratoriodes* R. and F., and the desert locust, *Schistocerca gregaria* (Forsk), has been made as a preliminary to work on the absorption of stomach poisons. Two observations of immediate interest are described here.

Albrecht[2] has described the *S* bend in the colon of *Locusta* as variable. In the work recorded here it was found that this region of the intestine first separates fæcal pellets from the midgut contents by a constriction, and then by bending breaks the peritrophic membrane between them (the various stages are shown diagrammatically in Fig. 1). At defæcation the *S* bend straightens out by the elongation of the abdomen, and the contents of the posterior region of the midgut move backwards as far as the anus (Fig. 1*b*). The centre of the colon then constricts to isolate the fæcal pellet (Fig. 1*c*), and almost simultaneously the *S* bend reforms (Fig. 1*d* and 1*e*). The process is complete in about 15 sec at 30° C. The *S* bend is present in both fed and unfed *Locusta*. The colon in *Schistocerca* also forms an *S* bend in a well-fed insect, but in a hungry insect the *S* bend is reduced, the colon remaining almost straight.

Locusta starved for 3–4 days retain an *S* bend without there being any food in the intestine, but starved *Schisto-*

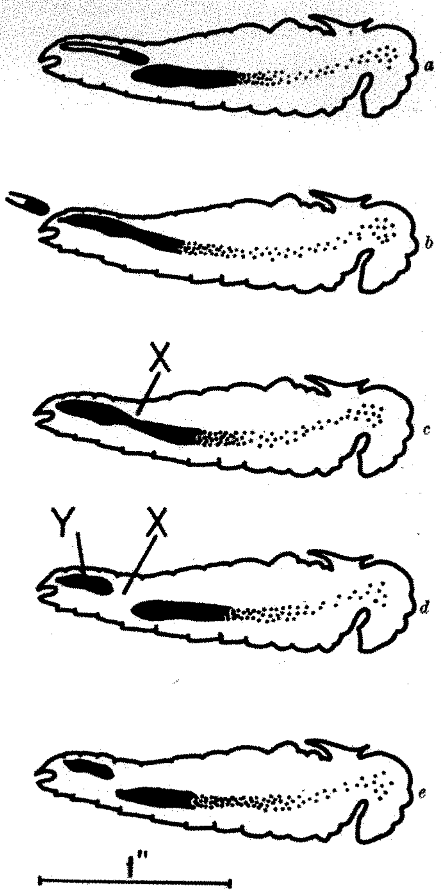

Fig. 1. Function of the *S* bend in the colon of *Locusta*. Tracings of radiographs of the gut contents of a locust that has received a barium meal are shown. The density of the contents is proportional to the amount of radiopaque substance present. The stages represented are: (*a*) appearance of the gut contents just before defæcation; (*b*) appearance at defæcation; (*c*) lumen of the central region of the colon is just beginning to contract (*X*); (*d*) lumen in the central region of the colon is occluded and a fæcal pellet has been isolated (*Y*); (*e*) *S* bend beginning to reform. (Compare the relative positions of the anterior edge of the fæcal pellet with the posterior edge of the food in the midgut in *d*, *e* and *a*)

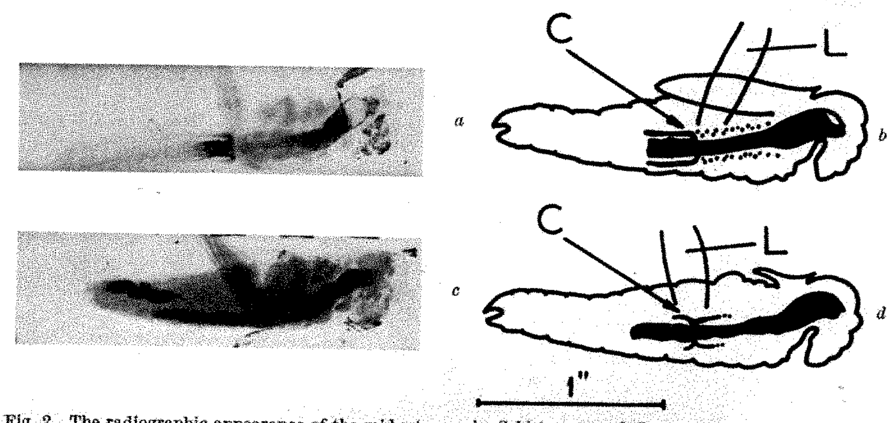

Fig. 2. The radiographic appearance of the midgut cæca in *Schistocerca* and *Locusta* that have received a barium meal: *a* and *b*, the radiographic appearance of the midgut cæca of *Schistocerca* (*C* in diagram); *c* and *d*, the radiographic appearance of the midgut cæca of *Locusta* (*C* in diagram). The stippled regions represent cæcal tissue that does not contain any visible radiopaque substance. *L* is the outline of the jumping leg

cerca do not retain the *S* bend, although, as Monchadsky and Skoblo[3] noted, some food residues do remain in the intestine. The disappearance of the *S* bend in *Schistocerca* may account for the normal retention of residual food through inability to produce discrete fæcal pellets If the locust is poisoned by means of a benzene hexachloride sandwich[4] the entire contents of the intestine may be ejected, at first as discrete pellets and finally as a continuous rod, which suggests that the quantity of food in the intestine normally controls the formation of the *S* bend

Opening into the anterior end of the midgut are six cæca, each cæcum consists of an anterior and a posterior arm In *Locusta* intestinal contents pass into both arms (Figs. 2*c* and *d*) and sections cut through the cæca show a peritrophic membrane extending into them In *Schistocerca* it is found that only the posterior arms of the cæca contain the intestinal contents (Figs 2*a* and *b*), the anterior arms remaining unfilled, a peritrophic membrane is found in the posterior arm The significance of this difference is at present unknown

Feeding Adult Mosquitoes on Solid Sugars

THAT mosquitoes may feed on flowers and sources of food other than blood has been observed many times Notable among these observations are those of Wesenberg-Lund[1], Haeger[2], West and Jenkins[3], and Sandholm and Price[4] Mosquitoes which visit flowers in greatest numbers are various species of *Aedes* According to most of the observations recorded, the food consumed is liquid or semi-liquid The only reference to indicate that mosquitoes may be able to feed on dry food was found in a paper by Downs and Arizmendi[5] on colonization of Mexican anophelines These two authors substituted powdered sugar for honey solutions which they normally supplied to the colonies and noted that females more readily took blood after having fed on powdered sugar They did not further elaborate on this part of their work, and there was no mention of how the powdered sugar was presented to the mosquitoes

Interest in the ability of mosquitoes to feed on solid sugars was raised by a recent chance observation made by me during the course of other experiments A female *Culex tarsalis* Coquillett was observed to probe the nearly dry remains of an insect smashed on the windshield of an automobile This female probed so persistently for about 0 5 h that an experiment was conceived to test the ability of mosquitoes to feed on dry or nearly dry material

In an initial test, glass slides were coated with syrupy sucrose solutions to which had been added ordinary food colours *C tarsalis* readily ingested this sticky material and the colour of the syrup soon became apparent in their bodies The slides were then air-dried for several days at room temperature, until the sugar completely crystallized This is a variation of the technique used by Bartlett[6] to examine dry sugar ingestion by parasitic Hymenoptera Mosquitoes were placed in glass vials, the open ends of which were covered with the prepared slides placed sugar-coated side down, or towards the mosquitoes Observations on feeding were made by placing the assembly under a dissecting microscope so that the manipulations of the mouth parts could be seen through the glass Cover-slips were substituted for the slides when observations were made at greater magnifications with a compound microscope

The technique described here has enabled me to observe many male and female mosquitoes feeding on solidified, dry sugar A secretion flows from the mouth parts of the mosquito, and the sugar is ingested in solution Individuals have been observed to feed for as long as 30 min without apparent diminution of the flow of secretion The coloured sugar solution appeared to move from the periphery of the labella, across its surface and into a central groove The food colour could be seen to accumulate within the abdomen during the feeding process Dissection showed that the coloured material accumulated in the œsophageal diverticula

The removal of the sugar during feeding left clear spots on the slides or cover glasses Forty or fifty mosquitoes, placed in a small cage, were able to remove nearly all the dry sugar from a heavily coated slide in 2–3 days A source of water was available in the cage at all times There appeared to be no regurgitation in the mosquitoes under test since previously ingested food colours were not noticeable in the secretion when the mosquitoes were later fed on uncoloured sugar crystals This is not regarded as conclusive evidence, however

It has been customary to describe mosquitoes as having piercing mouth parts According to these observations mosquitoes have sponging mouth parts as well The manner in which the mosquitoes dissolve and ingest dry sugar from the glass slides resembles the manner in which houseflies were observed to ingest sugar from slides prepared in the same way

The species of mosquitoes so far tested for ability to feed on crystallized sugar include the following *C tarsalis*, *Culex pipiens* L , *Culiseta inornata* (Williston), *Culiseta incidens* (Thomson), *Anopheles freeborni* Aitken, *Aedes sierrensis* (Ludlow), *Aedes aegypti* (L), and *Aedes taeniorhynchus* (Wiedemann)

Many individuals of the different species of *Culex* and *Culiseta* which have been tested readily fed on the dry sugars, while species of *Aedes* and *Anopheles* which were tested were not avid feeders on this material

The fact that there is a flow of secretion, or secretions, through the tips of the mouth parts during solid sugar feeding may have practical application in certain kinds of diagnostic and nutritional studies The fluids which flow to the tips of the mouth parts for dissolving food may be collected and examined for pathogens Burtt[7], for example, has examined the saliva of tsetse flies for the presence of trypanosomes He collected the saliva by interposing microscope slides between the flies and the laboratory animals which they attempted to bite Dr M M J Lavoipierre, Hooper Foundation, University of California College of Medicine, San Francisco, is at present trying the dry sugar feeding method to study the release of filarial worms from mosquitoes I have initiated an investigation of the feeding habits of field mosquitoes in relation to the kinds of substrates on which they rest

I thank S F Bailey and Dr M M J Lavoipierre for advice This work was supported in part by U S Public Health Service grant *E*2831

MICROBIOLOGY

Influence of Time of Addition of Antibiotic on the *in vitro* Life of Rumen Holotrich Protozoa

EXTENDED maintenance *in vitro* of rumen oligotrich protozoa has been reported by Coleman[1] Similar results have not been achieved with the rumen holotrich protozoa[2]. Coleman[1] suggested that to accomplish maintenance of the oligotrich protozoa satisfactorily, it was desirable to control the numbers of bacteria present rather than to eliminate them One of the principal differences between oligotrich and holotrich protozoa is that the former ingests and then digests starch granules, while holotrichs utilize mainly soluble carbohydrates[3] In view of this fact, it would seem possible that competition between bacteria and protozoa for available substrate may be greater in the case of holotrichs than with oligotrichs

Recent experiments in this laboratory have shown that when streptomycin plus penicillin are added to a suspension of rumen organisms prior to the addition of nutrients a marked inhibition of gas production occurs over that observed when the two are added simultaneously[4] Consequently, it seemed possible that adding antibiotics to holotrich cultures prior to the time nutrients are added to the cultures may provide more favourable growth conditions for the holotrichs An experiment to test such a possible effect was carried out

Rumen contents were collected from four sheep which had been fed a basal pelleted ration plus corn Inoculum was obtained by a method similar to that described by Oxford[5] The volume used was sufficient to provide a concentration of 20×10^3 holotrichs per ml of culture media *Isotricha* spp were predominant Cultures were maintained both in 16 mm × 150 mm culture tubes and in tissue culture flasks having an area of 15 cm^2 Seven different media were used (Table 1); the final volume for each culture was 2 ml The incubation temperature was 39° C Depleted media were removed each day by withdrawing the supernatant fluid after the cultures had been placed in an ice-bath for 3 min Fresh media containing nutrients were then added The cultures were gassed at all times with oxygen-free carbon dioxide Streptomycin, at a final concentration of 20 µg/ml of media, was added to half the cultures 1 h before the media was changed As this streptomycin was removed with the depleted media, streptomycin (20 µg/ml) was added to all cultures when the media were changed

The cultures were observed each day under a stereoscopic microscope and the maximum life of the culture recorded The results are shown in Table 2 Analysis of these results showed that the addition of antibiotic prior to the addition of nutrients significantly ($P < 0\ 001$) extended the life of holotrichs *in vitro*

In this experiment particulate material was not removed from the cultures, nor were they divided The maximum life obtained was 26 days (media 6) It will be of interest to determine whether division and/or removal of particulate material from the cultures will extend culture life longer It has been found in this laboratory that oligotrich cultures maintained for extended periods on media similar to that described by Coleman[1] have a maximum life of approximately 30 days if debris is not removed and the culture is not divided

Table 1 COMPOSITION OF MEDIA*

	1 /100 ml	2 /100 ml	3 /100 ml	4 /100 ml	5 /100 ml	6 /100 ml	7 /100 ml

‡ Media described by Coleman (ref 1)

§ Enzymatic 'vitamin free' casein hydrolysate (NBC)

¶ Clarified rumen fluid as described by Bryant and Robinson (ref 6), but autoclaved 20 min

‖ Ball-milled 3 days.

** Ground in a Wiley mill using a 60-mesh screen

Table 2 MAXIMUM CULTURE LIFE (DAYS)

Treatment		Media 1	2	3	4	5	6	7
Culture flasks	Antibiotic prior to nutrients	13	12	16	16	12	26	4
	Antibiotic with nutrients	8	11	6	10	12	18	3
Culture tubes	Antibiotic prior to nutrients	7	11	11	11	9	20	4
	Antibiotic with nutrients	7	7	6	6	7	11	3

The results presented here suggest that the inability to maintain holotrichs *in vitro* may be due, in part at least, to ineffective control of bacterial competition for available substrate It will be of interest to determine whether the rumen oligotrich protozoa can be more readily maintained using a similar technique

Viable bacterial counts[6] were made on the 17th day, from culture flasks containing media 6, and these indicated that the concentration of bacteria was not markedly affected by the different antibiotic treatments However, Gram stains and motility tests on bacteria isolated from the foregoing cultures suggested that the composition of the bacterial population was markedly affected, for example, organisms isolated from roll tubes containing approximately 30 colonies showed that 9 out of 9 of the organisms from the culture receiving antibiotic before nutrients were non-motile while 7 out of 10 of the organisms from the cultures not receiving antibiotic early were motile[7]

Work is now in progress to identify presumptively the isolated bacteria and to maintain holotrichs *in vitro* for extended time periods It will be of interest to determine whether the relationships indicated here are cause or effect relationships

Proteolytic Activity of Growth Media Filtrates from Non-pathogenic Species of *Verticillium*

THE production of proteolytic enzymes by micro-organisms is widely recognized, and several have been obtained from fungi In an attempt to identify the enzymatic activities of the filtrates of the growth media of members of the genus *Verticillium*, it was noted that filtrates of some non-pathogenic species of this group of fungi are able to lyse purified proteins and ovalbumin blocks The number of investigations dealing with the production of proteases in micro-organisms is low[1] Recently our interest has centred on the genus *Verticillium* as a part of our investigations on the lytic activity of a non-pathogenic strain of *Verticillium hemileiae* on uredospores of various rusts[2] The results reported here are a consequence of some studies on the effectiveness of certain species of *Verticillium* controlling rust, as well as their *in vivo* effect on the pathogenicity of these organisms To our knowledge, no results have been reported of the quantitative or qualitative aspects of proteolytic enzyme production by *Verticillium*

Cultures of *Verticillium* species were obtained from Estaçao Agronomica National of Oeiras (Portugal), University College of Swansea, Oregon State University and some were isolated by us Forty strains of the following species were considered in the survey *Verticillium albo-atrum*, *V tricorpus*, *V dahliae*, *V nigrescens*, *V lateritium*, and *V hemileiae*. The cultures, received in solid culture media, were transferred to a modified liquid 'Czapek Dox' media When *Verticillium hemileiae* is grown in a medium containing a protein substrate, very active proteolytic enzymes are elaborated into the medium These proteinases rapidly degrade the incorporated protein Aliquots of 100 ml of media were distributed in Erlenmeyer flasks of 250 ml capacity and autoclaved A sample of culture was transferred to each flask Cultures were incubated at room temperature (25° C) and grew luxuriously in all cases After specific time (15–20 days), the contents of flasks were centrifuged at 5,000g for 15 min or filtered The proteolytic activity was readily demonstrable in most of the cases using these filtrates The amount of proteinase produced was related to the amount of growth. Partial purification was accomplished using solid ammonium sulphate, the precipitate obtained between 60 and 80 per cent saturation being collected in a refrigerated centrifuge and dialysed This preparation could be stored for several months at 5° C with little loss of activity Commercially available bovine fibrinogen (Armour), trypsine (B D H), ovalbumin and casein (Light and Co) were used for the tests

Test procedures were selected which would allow us to compare the enzymatic activity of each strain. The presence of substrate specific proteolytic enzymes was detected by the use of methods which measured gelatin liquefaction, casein digestion and lysis of egg albumen clots After incubation at 27° C for 6 h, the degree of digestion of casein and egg albumen was examined by standard techniques[3] A variety of procedures have been developed to detect gelatin hydrolysis by fungi In the present study, the procedure of Pisano *et al* [4] was utilized to measure gelatinase activity by the strains of *Verticillium* The method measures the liquefaction of a purified calfskin gelatin in a tube Casein digestion was measured by the method of Dworschack *et al* [5] The amount of substrate, sodium caseinate, remaining after digestion was determined by precipitation with 5 per cent trichloroacetic acid For further investigations proteinase activity on casein substrate (1 per cent) was measured at pH 5 7 and 35° C following the method described by McDonald[6] The egg-white lytic ability of *Verticillium* species was determined using small cubic pieces of the coagulated protein in the growth media Erlenmeyer flasks containing the culture were incubated for two weeks at 28° C under static conditions The end-point was recognized by the digestion and disappearance of the solid albumen It was found that high gelatin liquefaction ability was associated with high egg-white digesting abilities, suggesting no differences in the character and composition of the proteolytic enzyme formed by the individual fungal strains

Growth of the organism was measured at various temperatures The results suggest that optimum temperature for growth and enzyme production was between 25° C and 28° C The stimulation effect of various carbohydrates and salts on the proteolytic enzyme formation on the organism growing in a minimal synthetic medium is being investigated

Attempts to obtain proteinase from non-proliferating cells of *Verticillium hemileiae* by incubating heavy suspensions in liquid media for several hours were unsuccessful Consequently a study was made of the effects of time and temperature of incubation and of composition of the media to determine if enzyme production could be effected independently and the results will be reported elsewhere

Extracts from non-pathogenic strains (in *Verticillium hemileiae*, and in much lower proportion from *V lateritium*) were found to show good activity against bovine fibrinogen, egg albumen and casein The *V. hemileiae* was also able to liquefy gelatin All the other species of *Verticillium* tested did not show any activity on the same proteins and were not able to digest gelatin It was also noted that optimum activity of the proteolytic strains was reached at one definite point during growth which corresponded to initial formation of spores

Dependence of proteinase production on the presence of protein has been shown for some organisms[7,8] but not for others[9,10] *V hemileiae* seems to require the presence of protein in the growth medium for proteinase production Synthetic peptides have not been tested as enzyme substrates The enzyme is greatly inhibited by thiol groups, cysteine, glutathione mercaptoacetate and mercaptoethanol acting as potent inhibitors Sodium acetate stimulated while chelating agents greatly reduced enzymatic activity This inhibition could not be relieved by the addition of various metal ions Nutritional experiments indicate that the enzyme is not formed or only in very low proportion when the organism is grown in mineral salts medium containing sucrose as carbon source

Many organisms have been shown to elaborate proteinases in direct relation to the amount of growth[11], and *Verticillium hemileiae* can be added to this group Excellent correlation was found between the amount of proteolytic activity exhibited by the *Verticillium* species and the lytic effect observed on the rust

As a result of this work, we can conclude that all the pathogenic species of *Verticillium* tested are pectolytic and non-proteolytic, in contrast with the non-pathogenic species which show high proteolytic activity but lack pectolytic activity[13,14].

VIROLOGY

Effect of Basic Dyes on Host-cell Reactivation of Ultra-violet-irradiated Phage

Strains of bacteria can be divided into two classes depending on their ability to effect dark repair of ultra-violet-induced damage to phage DNA[1] Those strains which manifest this ability are *hcr*$^+$ (host-cell reactivation positive) and those which show a reduced ability are *hcr*$^-$ (ref 2) Since post-irradiation exposure of bacteria to basic dyes reduces the ability to repair damage to their own DNA, presumably by hindering replication[3], a similar effect of these dyes on irradiated phage DNA might be expected Under these conditions, *hcr*$^+$ strains would then resemble *hcr*$^-$ strains This possibility has been confirmed

All experiments were performed with phage $T1$ The bacterial hosts were *Escherichia coli* strains B, B/r—a radio-resistant mutant, and strains B_{s-1} and B_{s-2}—two radio-sensitive mutants[4] Strains B, B/r and B_{s-2} are *hcr*$^+$ and strain B_{s-1} is *hcr*$^-$ (refs 5,6) Assays for plaque formation were performed by the agar layer technique, with Difco nutrient broth agar containing 0 5 per cent sodium chloride as both layers. Crystal violet was added to the plating media before autoclaving, and acriflavine after autoclaving Two-tenths of 1 ml of overnight aerated broth cultures containing about 10^9 organisms per ml were used for plating Irradiation of $T1$ and subsequent dilution prior to plating were carried out in 2 per cent CH_3COONH_4 The concentration irradiated was 1 5 × 10^8 phages per ml Plaque counts were made after 2 h incubation of plates at 37° C followed by overnight incubation at room temperature The apparatus used for irradiation has been described previously[7] Fractionated doses at a rate of 8 1 ergs/mm²/sec were given All experiments were performed under dim light to minimize both photodynamic action of the dyes[8] and photoreactivation[9]

Since basic dyes suppress the production of infectious particles by unirradiated phage[10], preliminary experiments were done to determine the minimum inhibitory concentrations for phage $T1$ Reduction in plaque formation was found when the concentrations of the dyes in the plating agar were more than 5 μg acriflavine per ml and more than 8 μg crystal violet per ml (the former value in agreement with Foster's value of 7 5 μg/ml (ref 10)) The concentrations used afterwards were kept below these minima Preliminary tests of adsorption of $T1$ in phosphate buffer prior to plating indicated that both unirradiated and irradiated phages were more than 95 per cent adsorbed to all the bacterial hosts, regardless of the presence or absence of 1 μg acriflavine/ml of buffer In addition, the plaque count in all cases was not affected by a 15-min suspension of $T1$ in buffer containing 1 μg acriflavine/ml Thus it seems certain that in later experiments, where the phage was plated on dye-containing agar, adsorption to the host was normal and no inactivation occurred prior to adsorption

If dye-free agar is used, all the *hcr*⁺ strains give the same survival curve for irradiated $T1$ (Fig 1) The decrease in slope at high doses has been interpreted[2] as due to repair of a portion of the ultra-violet-induced damage by a fraction of the host cells This fraction of cells is given by the extrapolated intercept of the final portion of the curve on the survival axis and is 30 per cent, in agreement with previous reports[2] (Starvation of cells increases the fraction to 100 per cent[11]) In contrast, when the *hcr*⁻ strain B_{s-1} is used as host, the $T1$ survival curve is nearly exponential and shows a very much greater rate of inactivation than that corresponding to the final portion of the curve obtained with *hcr*⁺ hosts

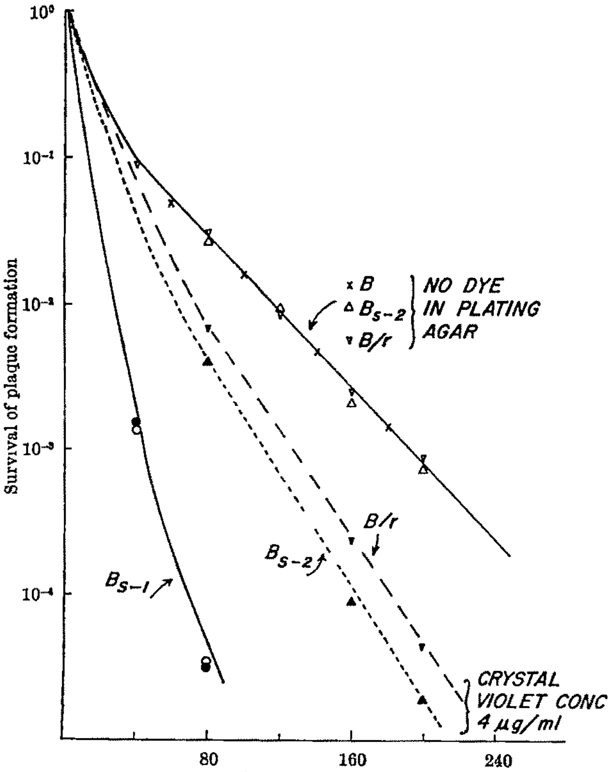

Fig 1 Effect of crystal violet on survival of ultra-violet-irradiated phage $T1$ in different host strains Curve for strain B_{s-1} open circles, no crystal violet in plating agar, solid circles, 4 μg crystal violet/ml of plating agar

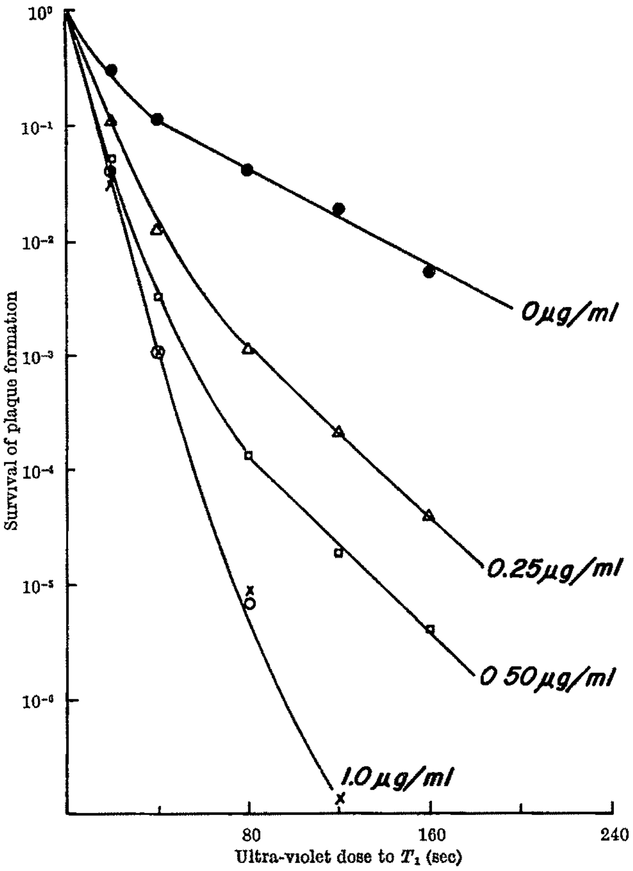

Fig 2 Effect of varying concentrations of acriflavine in the plating agar on the survival of $T1$ with strain B_{s-2} as host On the curve for 1 0 μg/ml, open circles are for B_{s-1} as host The crosses are for strain B_{s-1} without acriflavine in the plating agar

When the plating agar contains dye, the rate of inactivation increases markedly for the *hcr*⁺ hosts but there is virtually no effect for the *hcr*⁻ host (Figs 1 and 2) In the case of crystal violet at a concentration of 4 μg/ml, the effect is slightly more marked when B_{s-2} is used as host than when B/r is used Of the two dyes, acriflavine is more effective At a concentration of 1 μg acriflavine/ml, which corresponds to about one-third of the molarity for 4 μg crystal violet/ml, the phage survival curve, using B_{s-2} as host, coincides with the curve obtained by using the *hcr*⁻ B_{s-1} strain A greater efficiency of acriflavine compared with crystal violet has also been observed for the photodynamic inactivation of pneumococcal transforming DNA[12] and of the T phages[8] and for the retardation of mutation frequency decline and delay of mutation fixation in *E coli* after ultra-violet irradiation[3]

The explanation originally proposed by Garen and Zinder for the mechanism of dark repair of ultra-violet-induced damage to phage was genetic exchange between homologous regions of phage and bacterial DNA[1] This hypothesis was attractive because the phages for which this type of repair is observed—P_{22}, λ and T-odd (except $T5$)—are either temperate themselves or have mutants capable of establishing a lysogenic relationship of variable duration with their hosts[13] In addition, the base ratios for the DNA of these phages is the same as that for the host DNA[14] However, more recent evidence has been interpreted to the effect that the mechanism of repair is enzymatic[2,15]

Table 1 Effect of Dyes on Reactivating Fraction of Bacteria

Dye	Concentration (μg/ml)	Reactivating fraction of strain B_{s-1}	B/r
Crystal violet	0	$3\ 0 \times 10^{-1}$	$3\ 0 \times 10^{-1}$
	4	$1\ 4 \times 10^{-1}$	$2\ 2 \times 10^{-1}$
Acriflavine	0	$3\ 0 \times 10^{-1}$	—
	0 25	$3\ 0 \times 10^{-2}$	—
	0 50	$4\ 0 \times 10^{-3}$	—
	1 0	$(< 4\ 0 \times 10^{-3}\ ?)$	—

In view of these different hypotheses, one feature of the present results is of interest Figs 1 and 2 show clearly that the dyes increase the slope of the final portion of the *T*1 survival curve According to present interpretation, this means a decrease in the fraction of the damage which can be repaired Presumably the dyes reduce the accessibility of damaged regions to the repair enzyme However, besides this effect, the fraction of cells which can repair also decreases (Table 1) This suggests that bacterial DNA is also necessary for repair and that its action is impaired by the dyes Since the repair enzyme is apparently constitutive and present at the time of phage infection[2], the role of the bacterial DNA cannot be simply to produce it in response to infection by irradiated phage Instead, the bacterial DNA must be acting directly. Therefore it is possible that the two hypotheses regarding the nature of dark repair are not mutually exclusive This would mean that repair by genetic exchange between phage and bacterial DNA occurs and is mediated by a 'recombinase' enzyme Since all *hcr*⁻ strains reported so far show an increased sensitivity to ultra-violet radiation[2,5,6,16], the same mechanism of dark repair may rescue ultra-violet-irradiated cells as well as ultra-violet-irradiated phages

Since completing this work, we have learnt that the same possibility regarding dark repair has been derived from investigations of the recovery of diploid but not haploid yeast cells exposed to ionizing radiation The reader is therefore referred to these reports[17,18]

GENETICS

Stabilizing Selection and "Balanced Combinations of Polygenes"

In a recent paper, Gibson and Thoday[1] suggest that their analysis of an experiment with *Drosophila* populations submitted to long-term 'disruptive' and 'stabilizing' selection on the number of sternopleural chætæ confirms the ideas of Mather[2-5] that stabilizing selection can generate what is called "balanced combinations of polygenes". As Mather's theories and Gibson and Thoday's findings are important for our understanding of the maintenance of genetic variability in natural populations it seems worth while to make a closer comparison

Mather's theses can be summarized in the following points (1) Quantitative characters (as, for example, chætæ number in *Drosophila*) are under the control of a large number of genes (polygenes) each with only a small effect compared to total variability and to the effects of non-genetic variation Therefore, their presence and properties can only be assessed by statistical methods and they are not amenable to classical Mendelian analysis (2) Polygenes have no pleiotropic action (3) In chromosomes of wild populations, the polygenes are organized in combinations of alternating plus and minus genes (4) These 'balanced combinations' are built up under the influence of natural selection acting against individuals with values deviating from the optimal mean value of the character The selective disadvantage of these individuals must be caused by the deviation in the quantitative character itself as the polygenes have no pleiotropic action

Now Gibson and Thoday's results demonstrate (1) Variability in sternopleural chætæ number is at least partially under the control of genes with large effects the presence of which is shown by essentially classical Mendelian methods (2) These genes have important pleiotropic actions which are revealed by the lethality of certain combinations of the genes concerned (3) The maintenance of the genes in 'balanced combination' is not caused by the action of natural selection for an optimal mean value of sternopleural chætæ number but is brought about by the pleiotropic action of the chætæ number genes which causes recessive or dominant lethality of the − − combinations and + + combinations respectively

It will be noted that the findings of Gibson and Thoday are at variance with Mather's ideas on essential points Their model, however, shows some similarities with a situation described by Reeve and Robertson[6] where interacting recessive lethals seemed to be responsible for variation in body size

A most important point is the maintenance in repulsion linkage of the genes affecting chætæ number by their viability interactions instead of by natural selection towards an optimal value of the character itself It seems relevant here to point out that the concept of 'polygenic balance' depends largely on experiments with chætæ number in *Drosophila* Now extensive experiments have shown that differences in this character do not have much selective value[7] So polygenic balance for genes influencing this character must be based on a random distribution of the plus and minus genes along the chromosomes or on action of natural selection via the pleiotropic effects of these genes on characters which are more closely related to fitness The latter situation would result in a spurious cross-section of fitness for chætæ number[8]

Mather[2] has pointed out that if polygenic balance for a character is caused by the action of natural selection for an optimal mean value of this character, the distribution of polygenes in the chromosomes must be totally different from that of modifiers for mutant expression Therefore, a different response to artificial selection on naturally variable characters (as, for example, chætæ number in *Drosophila*) and on the expression of mutants has been postulated by Mather However, selection on the expression of the mutant ci^D (cubitus interruptus dominant)[9] in *Drosophila* shows the type of selection response which was thought by Mather[10] to be typical for the unravelling of 'balanced combinations of polygenes' Since the interruption of the 4th wing vein in ci^D, which was used as a quantitative character, does not exist in the normal wild-type fly, the distribution of its modifiers cannot be caused by natural selection acting on this character The similarity of response finds an easy explanation if genes governing a quantitative character are distributed at random along the chromosomes A random distribution will be found if the distribution of genes along the chromosomes in general is a random one Also if the distribution of polygenes, for example, bristle number, is governed by the action of natural selection on more important pleiotropic effects on various other characters the distribution of these genes will be at random relative to their action on bristle number

Transmission and Segregation of a Non-chromosomal Factor controlling Streptomycin Resistance in Diploid *Chlamydomonas*

CHROMOSOMAL and non-chromosomal mutations to streptomycin resistance have been described in *Chlamydomonas reinhardi*[1–3] The chromosomal mutants, *sr*-1, are resistant to low levels of streptomycin (50–100 μg/ml), possess a Mendelian pattern of inheritance, are closely linked or allelic, and lie in the left arm of linkage group IX The non-chromosomal mutants, *sr*-2, are resistant to high levels of streptomycin (500 μg/ml) and exhibit a uniparental pattern of inheritance When a mating is made between wild-type cells (*ss*) and cells of an *sr*-2 mutant, all the progeny in each tetrad are, with rare exceptions[1,4], endowed with the resistance-level of the mating type plus (*mt*$^+$) parent. The purpose of the present communication is to show that this pattern breaks down when diploids are made between *sr*-2 and *ss* cells and that a large proportion of the diploid clones segregate both resistant and sensitive cells during vegetative growth

The method for obtaining diploid cells in *C reinhardi* was recently devised by Ebersold[5], and only a brief description of the procedure will be presented here since it will be described in detail elsewhere[5,6] In the present experiments, reciprocal matings were made between two non-allelic arginine-requiring mutants according to the method of Ebersold and Levine[7] The two mutants, *arg*-1 and *arg*-2, complement in diploids[5,6] and are located six map units apart in linkage group I (ref. 7) The *arg*-2 parent always carried the *sr*-2 mutation while the *arg*-1 parent was always *ss*. In each experiment the cells were mated for 1 h and then the mating mixture was plated directly on minimal medium supplemented with sodium acetate[3] The plates were incubated in the light at 27° C for several days after which visible colonies had appeared on them

Since the original mating mixture had contained normal zygotes as well as diploid cells, the colonies included prototrophic haploid recombinants produced by germinated zygotes in addition to diploid cells Usually, the diploid colonies were larger than the colonies formed by the wild-type recombinants and they could be selected on this basis for further testing The most likely explanation of this phenomenon seems to be that the diploids begin to divide soon after being plated while the zygotes giving rise to wild-type recombinants probably do not begin to germinate for at least 36 h After a number of presumed diploid colonies had been isolated, they were tested for mating type and streptomycin resistance The *mt* gene lies in linkage group VI (ref 8) and assorts independently of the *arg* mutants so that one half of the wild-type recombinants are *mt*$^+$ and the other half are *mt*$^-$ Diploids, on the other hand, are always *mt*$^-$ in phenotype probably because *mt*$^-$ is dominant to *mt*$^+$ (refs 5 and 6) Therefore, the mating type test could be used to estimate the proportion of diploids and wild-type recombinants isolated in a given experiment Fortunately, all colonies tested proved to be *mt*$^-$ in the experiments to be discussed In a number of cases presumptive diploids were tested further by crossing them to haploid wild-type *mt*$^+$ cells and screening the resulting tetrads for arginine-requiring progeny The two arginine-requiring mutants can be distinguished by testing them on ornithine-containing medium since *arg*-1 will grow on either ornithine, citrulline, or arginine whereas *arg*-2 will only utilize arginine[7] These crosses showed that all the presumptive diploids carried both the markers

Table 1 TRANSMISSION AND SEGREGATION OF STREPTOMYCIN RESISTANCE AND SENSITIVITY IN DIPLOIDS DERIVED FROM RECIPROCAL CROSSES BETWEEN *sr*-2 AND *ss* CELLS

Cross	*sr*-2 *mt*$^+$ × *ss* *mt*$^-$			*ss* *mt*$^+$ × *sr*-2 *mt*$^-$		
Experiment	1	2	3	1	2	3
Percentage of *ss* cells in diploid clone						
100	5 55 (3/54)	1 24 (1/82)	1 85 (3/179)	24 50 (22/90)	44 50 (12/27)	6 70 (6/90)
100–80	0 00 (0/37)	1 86 (1/53)	0 00 (0/28)	0 00 (0/12)	15 10 (3/11)	4 91 (3/57)
80–60	5 10 (2/37)	3 72 (2/53)	3 50 (1/28)	12 50 (2/12)	15 10 (3/11)	8 25 (5/57)
60–40	7 65 (3/37)	13 00 (7/53)	7 02 (2/28)	12 50 (2/12)	15 10 (3/11)	16 30 (10/57)
40–20	15 30 (6/37)	7 45 (4/53)	10 50 (3/28)	12 50 (2/12)	10 00 (2/11)	34 40 (21/57)
20–0	20 40 (8/37)	22 30 (12/53)	38 60 (11/28)	31 90 (5/12)	0 00 (0/11)	26 20 (16/57)
0	45 80 (18/37)	50 40 (27/53)	38 60 (11/28)	6 25 (1/12)	0 00 (0/11)	3 26 (2/57)

Figures not in parentheses indicate the percentage diploids in a given cross belonging to each of the categories listed Figures in parentheses show the actual number of diploids in a given category and the total number of diploids examined In all crosses the *sr*-2 parent carried the *arg*-2 marker and the *ss* parent carried the *arg*-1 marker

Two important points emerge in the experimental results (Table 1) First, 50–> 90 per cent of the diploids arising from reciprocal crosses between *sr*-2 and *ss* cells produce mixed clones containing both resistant and sensitive cells This phenomenon cannot be explained by the assumption that the diploid nucleus is unstable since it has been found that three unlinked chromosomal markers do not segregate in a similar manner when the diploids are grown under non-selective conditions[6] Secondly, although 50 per cent or more of the diploid clones are mixtures of *sr*-2 and *ss* cells, a certain amount of the polarity characteristic of an ordinary cross is retained Thus, in a cross of *sr*-2 *mt*$^-$ × *ss* *mt*$^+$ up to 50 per cent of the diploid clones may be composed entirely of *ss* cells while less than 10 per cent are composed only of *sr*-2 cells In the reciprocal cross the reverse is true

If it is assumed that *sr*-2 and *ss* represent alternate mutational states of the same factor, then in a normal cross the transmission of the factor present in the *mt*$^-$ parent is usually blocked while the transmission of the factor present in the *mt*$^+$ parent is never blocked Diploids probably arise because some function necessary for normal zygote formation is never realized Whatever this function may be, the function which results in the uniparental transmission of the *sr*-2 factor is also impaired or missing in most newly formed diploid cells As a result, the majority of diploid cells contain both *ss* and *sr*-2 determinants and these determinants segregate during subsequent mitotic divisions

This work was carried out in the laboratory of Prof Norman H Giles, Yale University, and was supported by a Public Health Service training grant (2G-397-C1) I thank Prof Giles for providing the facilities and necessary space

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Mr R C Bond "A Commentary on the Change from Steam Traction on Great Britain's Railways, and some Thoughts on the Future" (Presidential Address)

Institute of Information Scientists (at the Swedenborg Society Hall, 20 Bloomsbury Way, London, W C 1), at 6 15 p m —Prof Sir Lindor Brown, C B E , F R S "Reading the Literature of Science" (Presidential Address).

Oil and Colour Chemists' Association, London Section (at Manson House, 26 Portland Place, London, W 1), at 7 p m —Dr T G Green and Mr M Thomas "Organic Coatings for Metal Containers"

Society for Analytical Chemistry, Biological Methods Group (in the Meeting Room of the Chemical Society, Burlington House, Piccadilly, London, W 1), at 7 p m —Meeting on "Assay of Virus Vaccines" Mr A J Beale "Manufacture and Control of Poliomyelitis Vaccine", Mr F Perkins "The Control Testing of Vaccines"

Society for Visiting Scientists (at the English Speaking Union, Dartmouth House, 37 Charles Street, London, W 1), at 7 30 p m —Discussion on "Science and the City" Chairman Baron Fleck of Saltcoats K B E , F R S Speakers Dr H M Finniston, Mr E P Hawthorne and Dr J V Dunworth

Thursday, October 24

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr W G Chaloner 'Fossil Hayfever" *

Chemical Society (in the Lecture Theatre, Middlesex Hospital Medical School, Cleveland Street, London, W 1), at 2 15 p m —Symposium on 'Peptide Chemistry"

Institution of Civil Engineers, Engineering Management Group (at Great George Street, Westminster, London, S W 1), at 5 30 p m — Informal Discussion on "The Use of the Critical Path Method" introduced by Mr D J Armstrong

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m — Dr L B Strang "Changes in the Lungs at Birth" (Third of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

Institute of Refrigeration (at the National College for Heating Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road London, S E 1), at 6 p m —Prof S A Andersen "Cooling and Dehumidification of Moist Air in Cold Stores"

Society of Instrument Technology (at the Royal Institution, Albemarle Street, London, W 1), at 6 p m —Prof Dennis Gabor, F R S "Technology, Life and Leisure" (Thomson Lecture)

Royal Institute of Chemistry, London Section—Kent Sub-Section (at the Medway College of Technology, Horstead, Maidstone Road, Chatham), at 7 p m —Prof J C Tatlow "Aromatic Fluorocarbon Chemistry"

Institution of Mechanical Engineers, Hydraulic Plant and Machinery Group (at Highbury Technical College, Dovercourt Road, Cosham, Portsmouth), at 7 30 p m —Mr A Gasiunas and Mr W P Lewis "Hydraulic Jet Propulsion—a Theoretical and Experimental Investigation into the Propulsion of Seacraft by Water Jets"

Friday, October 25

Association of Applied Biologists, and British Ecological Society (at the British Museum (Natural History), Cromwell Road, London, S W 7), at 10 50 a m —Symposium on "Dispersal as a Factor in the Distribution and Regulation of Animal Populations, and its Economic Significance"

Royal Astronomical Society (at Burlington House, Piccadilly, London, W 1), at 4 15 p m —Sir Harold Jeffreys, F R S "How Soft is the Earth ?"*

Institution of Mechanical Engineers, Thermodynamics and Fluid Mechanics Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "The Impact of Fouling on Heat Transfer Design"

Society of Chemical Industry, Pesticides Group (joint meeting with the Manchester Section, at the Literary and Philosophical Society, 36 George Street, Manchester 1), at 6 30 p m —Mr G Edmund-Jones "Crop Protection in Cotton".

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m — Prof K W Cross "A Baby's First Breaths"

Saturday, October 26

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Dr F Hall "Animal Communication" *

Monday, October 28

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 5 p m —Dr G Melvyn Howe "A National Atlas of Disease Mortality in the U K"

British Society for the History of Science (in the Council Room of the Science Museum, Exhibition Road, London, S W 7), at 5 30 p m — Dr J L Russell "Kepler's Planetary Laws 1609–66"

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Solid State Nanosecond Techniques" opened by Mr A F Boff, Dr R E Hayes, Dr P Orman and Mr A R Owens

Institution of Electrical Engineers, Science and General Division (at Savoy Place, London, W C 2), at 5 30 p m —Ir R A Grijseels "Self-Checking in the SATCO Air Traffic Control System"

Society of Chemical Industry, London Section (at Shell Centre London, S E 1), at 6 30 p m —Scientific Film Evening

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Experimental Officer (if under 22 years of age a G C E in four subjects including English and Mathematics at "O" level and two scientific subjects, preferably chemistry and biology at "A" level, if over 22 a pass degree, including chemistry, or an equivalent qualification), to assist in chemical and plant physiological research on storage of fresh foods —The Secretary Low Temperature Research Station, Agricultural Research Council, Downing Street, Cambridge (October 26)

Lecturers and Assistant Lecturers in the Department of Psychology—The Secretary, The Royal College of Science and Technology, George Street, Glasgow, C 1 (October 26)

Lecturer or Assistant Lecturer in Statistics—The Registrar, The University, Keele, Staffs (October 31)

Post-doctoral Research Fellow in the School of Natural Philosophy, St Salvator's College, St Andrews, for work on relaxation time measurements in solids by spin-echo techniques—The Secretary, The University, St Andrews, Scotland (October 31)

Lecturer in Electrical Engineering at the University of Canterbury, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, November 1)

Assistant Lecturer (preferably with industrial and research experience, and prepared to become interested in research in paper technology) in the Department of Paper Science—The Registrar, Manchester College of Science and Technology, Manchester 1 (November 2)

Director (with many years' experience in theoretical and applied statistics and related disciplines at the post-doctoral level and adequate administrative experience) of the Institute of Statistics, University of Ghana —The Registrar, University of Ghana, P O Box 25, Legon, Accra, or The Assistant Registrar (Overseas), University of Ghana, 15 Gordon Square, London, W C 1 (November 6)

Assistant Director of Research in the Statistical Laboratory, to engage in, and supervise, research in mathematical statistics, to undertake consulting work, especially in connexion with the physical sciences, and to help with the course for the Diploma in Mathematical Statistics— The Secretary, Appointments Committee, Faculty of Mathematics, Arts School, Benet Street, Cambridge (November 9)

Assistant Lecturer (preferably with experience or special interest in biochemistry and nutrition) in the Agricultural Chemistry Section of the Department of Agriculture—The Registrar, The University, Leeds 2 (November 11)

Chair of Chemistry—The Secretary, Royal College of Science and Technology, George Street, Glasgow, C 1 (November 15)

Junior Lecturer (preferably interested in cytological or physiological aspects of vertebrate reproduction) **in Zoology**—The Secretary, The Medical College of St Bartholomew's Hospital, West Smithfield, London, E C 1 (November 18)

Chair of Mechanical Engineering at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W C 1 (November 21)

Chair of Control Engineering within the School of Engineering Science—The Secretary and Registrar, The University College of North Wales, Bangor, North Wales (November 25)

Chair of Microbiology—The Registrar, University College of South Wales and Monmouthshire, Cardiff (November 29)

Scientific Officer (Palæontologist) (with a B Sc (Hon) or M Sc with zoology and/or geology as leading subjects) with the New Zealand Geological Survey, Lower Hutt, to undertake research on the systematics and history of Tertiary molluscan fauna of New Zealand and thus to contribute to their use in stratigraphy—The High Commissioner for New Zealand, New Zealand House, Haymarket, London, S W 1, quoting Ref No B 13/18/18/2758 (December 18)

Assistant Experimental Officer (with at least a pass degree in agriculture or equivalent) **in the Department of Grass/Animal Ecology**, to assist in the investigation of factors affecting the health and productivity of sheep—The Secretary, The Grassland Research Institute, Hurley, Maidenhead, Berks

Assistant Lecturer, Grade B (with a good honours degree in zoology, and preferably some industrial and/or teaching experience), **to teach Zoology** to G C E "A" level and B Sc General Degree level—The Principal, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex

Assistant Lecturers and **Lecturers in Electrical Engineering** with opportunities to specialize in any branch—The Secretary, Northampton College of Advanced Technology, St John Street, London, E C 1

Geneticist (with a good honours degree), to work on developmental genetics and gene action in *Drosophila*—The Secretary, Poultry Research Centre, Agricultural Research Council, King's Buildings, West Mains Road, Edinburgh 9

Histology Technician, for a research programme concerned with the effects of radiation on tissues—The Secretary, The Medical College of St Bartholomew's Hospital, London, E C 1

Laboratory Assistant (with experience of animal house maintenance and work in experimental physiology)—The Secretary, Royal College of Advanced Technology, Salford, Lancs, quoting Ref CH/13

Lecturer in Veterinary Physiology—The Registrar, The University, Liverpool, quoting Ref No CV/424

Lecturer or **Assistant Lecturer** (graduate in microbiology or in chemistry/biochemistry with training or experience in microbiology)—The Principal, National College of Food Technology, St George's Avenue, Weybridge, Surrey

Lecturer (with at least two years' experience with a digital computer, a sound knowledge of the construction or modification of processors, and of the application of computers to the solution of technological problems) **in the Computer Centre**—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref 31/G

Research Assistant (physicist or mathematician, preferably post-doctoral, with an interest in observational science) at the Imperial College Field Station near Ascot, for a D S I R sponsored study of cloud- and rain-systems—The Meteorology Department, Imperial College of Science and Technology, London, S W 7

Research Fellow in Endocrinology in the Department of Anatomy, to study the influence of environmental and other factors on seasonal changes in the ferret—Dr W P Dallas Ross, The Department of Anatomy, The Medical School, Birmingham 15

Research Fellow (with a higher degree or other substantial research experience) **in either the Department of Electrical Engineering or the Department of Electronics**, for work on electrical materials, machines and apparatus, or on microwave and quantum electronics (including lasers)—The Registrar, The University, Southampton

Senior Research Fellow (with an honours degree) **at the Advanced School of Automobile Engineering**, to carry out research, under the sponsorship of the Nuffield Foundation, into vibration in relation to vehicle comfort—The Registrar, The College of Aeronautics, Cranfield, Bletchley, Bucks

Senior Technician (male over 21, with G C E "A" level chemistry and physics or equivalent, and several years' experience in a biochemical or organic chemical laboratory) **for a Biochemical Laboratory** engaged in cancer research—The Secretary, Institute of Nuclear Medicine, Middlesex Hospital Medical School, London, W 1

HEXAFLUOROBENZENE

AND ITS DERIVATIVES

These compounds are being made available world-wide for the first time, following the discovery by Imperial Smelting Corporation Ltd. and at the University of Birmingham, of a new and attractive synthetic route. They open up exciting possibilities in such fields as polymers, pharmaceuticals, dyestuffs and agricultural chemicals, where the presence of a fluorinated aromatic ring may lead to novel properties. Many companies and university research departments are taking experimental quantities of these fluorocarbon compounds and carrying out their own programmes of investigation.

APPOINTMENTS VACANT

ROYAL PERTH HOSPITAL
WESTERN AUSTRALIA
HOSPITAL MICROBIOLOGIST

Applications for the above post are invited from medical graduates with suitable experience in Microbiology The Hospital Department of Microbiology is under the control of the Director of Hospital and University Services in Microbiology

The successful candidate will be required to assist the Director (Professor N F Stanley) in the administration of the routine laboratory and clinical services of the Hospital Department of Microbiology, to act in the absence of the Director, and to carry out special investigations from time to time

Royal Perth Hospital is the main teaching hospital of the Medical School of the University of Western Australia The Hospital Department of Microbiology is well equipped, adequately staffed for the performance of all modern microbiological techniques, functions in close association with the University Department of Microbiology in the adjacent School of Medicine and the Virus Research and Diagnostic Laboratory of the Department of Public Health

SALARY Within the range of £A3,800 to £A4,350 per annum, commencing rate according to qualifications and experience Salary will commence from the date the appointee takes up duty

CONDITIONS OF SERVICE Include annual leave, long service leave (three months on full pay after each seven years service) and sick leave Study leave may be granted as a privilege for some special purpose approved by the Board Contribution to the State Superannuation Scheme is required, or alternatively, the Hospital would consider subsidizing the appointed officer's existing commitments under an approved scheme or endowment policy

TRANSPORT EXPENSES A travel grant equivalent to minimum First Class sea passage will be provided for successful applicant and family (under 16 years of age), together with an allowance of £S200 for the cost of removal of personal effects, etc (excluding furniture and motor vehicle), subject to a bond to remain in the Hospital's service for a minimum period of three years

A memorandum of Information including further details of the Department of Microbiology is available upon request

Further information concerning Royal Perth Hospital and the State of Western Australia may be obtained from the Agent General for Western Australia, Savoy House, 115 Strand, London, W C 2

Applications in writing should include date of birth, qualifications, experience, present and previous appointments, a list of publications, a recent photograph and the names and addresses of three referees

CLOSING DATE November 30, 1963

Joseph Griffith,
ADMINISTRATOR

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF ANATOMY
RESEARCH FELLOWSHIP IN THE PHYSIOLOGY OF REPRODUCTION

Applications are invited for a Research Fellowship in the Department of Anatomy (Professor Sir Solly Zuckerman, C B , F R S) to study the physiology of reproduction and in particular to investigate the control of fertility in primates and lower mammals The salary will be determined according to qualifications and experience F S S U and family allowance will be paid Initially the appointment will be for a period of two or three years, which may be extended

Further particulars may be obtained from the Assistant Registrar, the Medical School, Birmingham, 15, to whom applications, naming two referees, should be sent as soon as possible

AUSTRALIA — NEW SOUTH WALES DEPARTMENT OF AGRICULTURE

CAREERS FOR PROFESSIONAL OFFICERS

Applications are invited for the following positions in the New South Wales Department of Agriculture, Australia Commencing rate in each case according to qualifications and experience.

ECONOMICS RESEARCH OFFICERS

(ref 234/A) Salary £A1,403 (three-year graduate), range £A2,123 Honours graduate or a four-year graduate with an appropriate degree commencing salary £A1,473 Progression to £A2,393 subject to specified conditions Appointee required to undertake research in Agricultural Economics, Farm Management or the Marketing of Farm Products Should possess a degree in Agricultural Economics, Agricultural Science, Economics or equivalent qualifications Headquarters Initially Sydney, but appointee may be required to serve in any part of New South Wales

CHEMIST (TOBACCO RESEARCH)

(ref 234/B) Division of Science Services Salary £A1,405 (three-year graduate), range £A2,305, four-year graduate commencing salary £A1,505 Progression to £A2,655 subject to special conditions Degree in Agricultural Science or Science and postgraduate experience in organic chemistry essential Appointee required to undertake research, in association with other tobacco research workers, into problems related to the production, manufacture and smoking quality of tobacco and may be given a period of training in this specialized field Headquarters initially will be at the Department's Science Services laboratories at Rydalmere, near Sydney, and facilities will be available for field trials Final location will probably be in a country tobacco growing area

AGRONOMISTS (ref 234/C) Minimum salary (graduates) £A1,473 (non-graduates) £A1,023 with progression to £A2,123 subject to meeting requirements Opportunities exist for further promotion to £A2,453 and beyond Vacancies exist in pastures, weeds and crop research, general agronomy and extension with field crops and vegetables Qualifications B Sc Agr , B Rural Sc , or Diploma of the Hawkesbury or Wagga Agricultural Colleges or equivalent Must be prepared to serve in any part of the State

VETERINARY RESEARCH OFFICERS (ref 234/G) Veterinary Research Station, Glenfield Salary £A1,613 with range to £A2,343 subject to meeting requirements Opportunities exist for further progression to £A2,618 and beyond Qualifications B V Sc or equivalent essential, postgraduate experience in a veterinary diagnostic or research laboratory desirable Duties Examination of specimens in connection with stock diseases—one appointment will be in the field of bacteriology and pathology and the other in virology Opportunity to conduct research in these fields available

SPECIAL LIVESTOCK OFFICER

(Beef Cattle, Horses and Goats) (ref 234/H) Salary £A2,273 range £A2,453 Degree in Veterinary Science, Agricultural or Rural Science essential The position holds prospects for advancement Appointee may be required to serve in any part of the State

CHEMIST (SOIL SURVEYOR)

(ref 234/L) Salary £A1,405 (three-year graduate) range £A2,305 Honours graduate or a four-year graduate commencing salary £A1,505 Progression to £A2,655 subject to satisfying certain conditions Applicants should possess B Sc (Agr), B Sc , or equivalent degree qualification Duties would principally comprise carrying out soil surveys in any part of New South Wales, preparation of data and draft maps from surveys, laboratory work, and such other duties as may be required Headquarters at Division of Science Services, Rydalmere -

FRUIT RESEARCH OFFICERS

(ref 234/D) Minimum Salary (graduates) £A1,473, (non-graduates) £A1,023 with range to £A2,123 subject to meeting requirements Opportunities exist for further promotion to £A2,453 and beyond Vacancies at Sydney, Alstonville Tropical Fruit Research Station (near Lismore) and the Lower Murray Research Station at Dareton Duties include investigations into fruit growing problems associated with tropical, sub-tropical and deciduous fruits Degree in Agricultural Science or equivalent essential

RESEARCH AGRONOMIST (Weed Control) (ref 234/E) Yanco Agricultural Research Station Salary £A1,473 with range to £A2,123 subject to meeting requirements Opportunities exist for further progression to £A2,453 and beyond Appointees will be required to undertake research on the control of weeds occurring mainly under irrigation in the south-western districts of New South Wales Considerable scope for the appointee to develop research with weeds in rice, vegetables, irrigated pastures or irrigation ditches Degree in Agricultural Science or its equivalent essential

VETERINARY OFFICERS

Division of Animal Industry (ref 234/J) Salary £A1,613 with range to £A2,343 subject to meeting requirements Opportunities exist for further progression to £A2,618 and beyond Degree in Veterinary Science or equivalent essential Duties Investigations in stock and poultry disease outbreaks , take regulatory action in cases of scheduled diseases Appointee must be prepared to serve anywhere in the State

SENIOR RESEARCH OFFICERS

(ref 234/K) Plant Nutrition and Cereal Chemistry, Tamworth Agricultural Research Station Salary £A2,455 range £A2,655. Prospects of progression to £A2,755 subject to meeting certain requirements (If not possible to appoint an experienced officer consideration may be given to appointing a Research Officer with commencing rate up to £A1,905 with prospects of further progression subject to meeting requirements) Duties Plant Nutrition—the study of environment on uptake and utilization of nutrient elements by the major crops and pasture species grown in the northern part of New South Wales Cereal Chemistry—original research in cereal chemistry and routine quality evaluation of cereal samples from breeding and experiment plots Qualifications appropriate postgraduate experience desirable The recently established Research Station, situated seven miles from the City of Tamworth serves as a centre of agricultural research for a large section of the north-west of New South Wales Excellent facilities for research Appointees will be expected to provide research leadership and, where necessary, in-Service training for junior officers in their particular fields

LECTURER IN MICROBIOLOGY

(ref 234/F) Hawkesbury Agricultural College, Richmond Salary £A1,403 with range £A2,123 subject to meeting requirements Opportunities exist for further progression to £A2,393 and beyond Applicants must possess appropriate degree of a recognized University and have ability to lecture and conduct examinations and give practical instruction and demonstrate, where necessary , required to lecture in Microbiology in Agriculture, Food Technology and Dairy Technology Diploma Courses, and to share disciplinary and other College duties with other Lecturers Cottage at moderate rental available within four miles of College

Please write for application forms to the New South Wales Government Offices, 56 Strand, London, W.C.2, quoting the reference number of the appointment in which you are interested

THE CLOSING DATE FOR APPLICATIONS IS NOVEMBER 11, 1963.

CHEMIST OR BIOCHEMIST REQUIRED IN Department of Chemical Pathology for work on metabolism of steroid hormones involving microchemical and radiochemical techniques Some experience in chemical work preferred but recent graduate would be trained Opportunity for study for higher degree —Apply Secretary, St Mary's Hospital Medical School, London, W 2

ENTERIC REFERENCE LABORATORY Technician wanted to assist in M R C supported research project, mainly concerned with bacterial polysaccharides Experience in chromatographic techniques an advantage N H S scales of pay according to qualifications and experience —Applications to the Director, Central Public Health Laboratory, Colindale Avenue, N W 9

IMPERIAL CHEMICAL INDUSTRIES LIMITED

PETROCHEMICAL AND POLYMER LABORATORY

REQUIRES (BETWEEN NOW AND AUGUST 1964)

PHYSICISTS, PHYSICAL CHEMISTS OR ENGINEERS

TO WORK ON POLYMER PHYSICS

The Petrochemical and Polymer Laboratory was formed in 1962 to carry out long-range exploratory chemical research, and to assess the commercial possibilities of the products of this research Its ultimate strength will be 60 chemistry graduates and 10 Engineers together with about 25 graduates engaged in various aspects of physics The latter will give direct support to, and guidance of, the chemical effort and will seek fundamental information on the physics of polymers and petrochemicals

The Laboratory will be similar to the good academic research laboratories as regards intellectual atmosphere, equipment and general facilities The publication of scientific work and communication with researchers elsewhere will be encouraged as much as possible.

In the physics department there are vacancies for two types of graduate

(a) Research workers experienced in the fundamental study of polymer melt flow or solid state physical properties They should be interested not only in the pure physics of polymers but also in the way properties are dependent upon chemical structure Candidates most likely to be suited to this work are Honours graduates in physics or physical chemistry

(b) Physicists or technologists interested in correlating the behaviour of polymers in laboratory experiments with their performance in practical processes Examples of this work are the analysis of (a) screw extrusion in relation to polymer visco-elasticity, or (b) the mechanical strength of a moulding in terms of the inherent strength of the polymer and the effect of thermal and shear history Candidates for posts in this field should be graduates in physics or related subjects and although some experience of such work would be an advantage, a more important qualification is an intelligent enthusiasm for the analysis of technological processing

Applications quoting ref P/P26 should be made to The Laboratory Head, I C I Ltd , Petrochemical and Polymer Laboratory, P O Box 11, The Heath, Runcorn, Cheshire

---

UNIVERSITY OF SHEFFIELD

Applications are invited for two posts as Research Assistant to take part in programmes designed to study (1) human chromosome abnormality and associated disorder , and (2) chromosome behaviour in normal and abnormal karyotypes Suitable for graduates with a first degree in the Biological Sciences or Chemistry Initial salary up to £1,100 per annum, according to qualifications and experience

Please apply to the Secretary, Genetics Department, the University, Sheffield, 10, giving full details of qualifications and experience and the names of two referees

---

UNIVERSITY OF NOTTINGHAM

Applications are invited for a Lectureship in Physics Candidates should have research experience in nuclear magnetic resonance Salary scale £1,250 to £2,150 per annum, initial salary according to qualifications and experience, plus membership of the Universities pension scheme and children's allowance

Conditions of appointment and application form, which should be returned by Wednesday, November 27, 1963, from the Registrar

---

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF ANATOMY

RESEARCH FELLOW IN ENDOCRINOLOGY

Applications are invited for a Research Fellowship in the Department of Anatomy (Professor Sir Solly Zuckerman, C B , F R S) to study the influence of environmental and other factors on seasonal changes in the ferret The salary will depend on qualifications and experience and will include F S S U and family allowance benefits

Further particulars may be obtained from Dr W P Dallas Ross, the Department of Anatomy, the Medical School, Birmingham, 15, to whom applications, naming two referees, should be sent as soon as possible

---

SENIOR II TECHNICIAN REQUIRED FOR work on tumour destroying virus in tissue culture General tissue culture experience necessary human cell culture experience an advantage Salary £945 to £1,445 per annum according to age and experience —Written applications should reach Dr J G Bennette Courtauld Institute, Middlesex Hospital, London, W 1 before November 1, 1963

UNIVERSITY OF CAPE TOWN

SENIOR LECTURER OR LECTURER IN MATHEMATICAL STATISTICS

Applications are invited from persons with special qualifications in Mathematical Statistics for the post of Senior Lecturer or Lecturer in the Department of Mathematics The present salary scales are Senior Lecturer, R 3,520 by R 120 to R 4,120 (£1,760 by £60 to £2,060) per annum Lecturer, R 2,680 by R 120 to R 3,520 (£1,340 by £60 to £1,760) per annum The salary scales are under review, and it is hoped that improved scales will be introduced from the beginning of 1964 The initial salary will be dependent upon the qualifications and experience of the successful applicant, who would be expected to commence his duties as soon as reasonably possible

Two copies of the application must be sent to the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (from whom memoranda giving the general conditions of appointment, travel allowance on appointment, and detailed information about the department and its programme of teaching and, research in Mathematical Statistics should be obtained), not later than November 11, 1963 A third copy of the application should be sent direct by airmail to the Registrar, University of Cape Town, Private Bag Rondebosch, South Africa, to reach him by the same date The University reserves the right to appoint a person other than one of the applicants or else to make no appointment

---

NATIONAL RESEARCH COUNCIL OF CANADA

POST-DOCTORATE FELLOWSHIPS

1964-65

Approximately 150 Fellowships will be awarded for 1964-65 by the National Research Council Of these, 40 will be tenable in National Research Council laboratories, 15 in laboratories of the Department of Agriculture, 4 in laboratories of the Department of Forestry, 15 in laboratories of the Department of Mines and Technical Surveys 4 in the laboratories of the Department of National Health and Welfare, 2 in the Fisheries Research Board of Canada laboratories, 2 in the Department of Transport—Meteorological Service of Canada laboratories, 8 in the laboratories of Atomic Energy of Canada Limited, and 60 in laboratories of Canadian universities

Applicants should be not more than 35 years of age and should possess a Ph D degree from a recognized university, or expect to obtain such a degree before taking up an award (Candidates having equivalent research experience may be considered) There are no restrictions regarding nationality of applicants, but successful candidates must meet all Canadian immigration requirements

The annual stipend, which is free of income tax, is $4,000 for single Fellows and $5,000 for male Fellows who are married

The fields in which Fellowships are available in the laboratories of the National Research Council, the Department of Agriculture, the Department of Forestry and the Department of Mines and Technical Surveys are described in greater detail in booklets that may be obtained on request, together with application forms Applicants who are interested in Fellowships in the universities may write directly to these institutions, or to the National Research Council for information The fields of interest should be stated in the initial inquiry in order that appropriate information may be supplied The closing date of the competition is January 15, 1964

Inquiries should be addressed to

Awards Officer,
National Research Council,
OTTAWA 2, Canada

or to :

Chief Scientific Liaison Officer,
National Research Council of Canada,
Africa House,
Kingsway,
LONDON, W C 2, England

UNIVERSITY OF SHEFFIELD

DEPARTMENT OF PHYSICS

Applications are invited for two posts of Research Assistant to Professor N H March tenable from January 1, 1964 One is a senior post for work on the angular distribution of charge in the unit cell of transition metals Applicants should have a Ph D in Theoretical Physics or equivalent research qualifications Initial salary according to age and experience not less than £1 000 a year The other post is a junior one for work on the density matrix theory of impurities and imperfections in metals Applicants will be encouraged to read for a higher degree, and financial support at least equal to that of a D S I R postgraduate studentship will be available

Applications should be sent to the Registrar The University, Sheffield, 10, by November 9, 1963

AEI

PHYSICISTS

The AEI RESEARCH LABORATORY, RUGBY, is engaged on an extensive investigation of laser materials and applications of lasers There are several opportunities for high quality physicists to participate in these investigations Four specific vacancies are set out below but applications from any well qualified scientist keen to work in this field will be considered

(1) A senior physicist to lead a team investigating the applications of lasers

(2) A physicist for work on theoretical aspects of crystal fluorescence

(3) A physicist to study semiconductor laser materials using resonance techniques

(4) A physicist to investigate crystalline laser materials using infra-red spectroscopic techniques

Applicants should possess a good honours degree or Dip Tech and relevant postgraduate academic or industrial research would be advantageous Initial salary will depend upon qualifications and experience Applications should be addressed to

AEI RESEARCH

DIRECTOR OF AEI RESEARCH LABORATORY, RUGBY, WARWICKSHIRE.

THE GENERAL ELECTRIC COMPANY LTD.
HIRST RESEARCH CENTRE

Enquiries are invited from

HONOURS GRADUATES
in Physics, Electrical Engineering and Mathematics

for (1) Research and Development in Lighting, involving the study of vision and its bearing on the design of installations, the measurement of optical, thermal, mechanical and electrical properties of materials, the experimental design and testing of equipment, and the planning of special lighting applications (for land, sea and air), and (2) Work on Discharge Lamp Research discharge lamp circuitry and ballast design, and also on the fundamental aspects of discharge in gases

There is one opening for a candidate having a pass degree or H N C

Applicants available now or later in 1963 *should apply in writing to the Staff Manager (Ref B/913/G),*

THE GENERAL ELECTRIC COMPANY LIMITED
Hirst Research Centre, Wembley, Middlesex

NATIONAL COLLEGE OF FOOD TECHNOLOGY
ST GEORGE'S AVENUE, WEYBRIDGE, SURREY
Principal J D Mounfield, M Sc Tech, Ph D, F R I C

Applications are invited from graduates in microbiology or in chemistry/biochemistry with training or experience in microbiology, for a teaching post at the College Facilities for research are available Appointments may be made at Lecturer or Assistant Lecturer level Salary scales Lecturer, £1,670 by £45 to £1,895 per annum, Assistant Lecturer, £930 to £1,550 per annum Starting salary dependent on qualifications and experience

Application forms (obtainable from the College), should be sent to the Principal as soon as possible

---

HORTICULTURE ADVISORY OFFICERS National Agricultural Advisory Service (Ministry of Agriculture, Fisheries and Food) Six or more pensionable posts for men or women at least 20 on October 1, 1963 with degree in horticulture (or closely related subject), N D H, or equivalent qualification, and at least one year s full-time practical experience National salary scales Grade IV, £769 to £1,064, Grade III, £1,157 to £1,821 Starting salary may be above minimum in both cases Promotion prospects—Write Civil Service Commission, 23 Savile Row, London, W 1, for application form, quoting 5766/63/7 Closing date November 12, 1963 (1)

UNIVERSITY OF MANCHESTER

Applications are invited for the posts of Lecturer and Assistant Lecturer in the Department of Physics in the Faculty of Science The research interests of applicants should lie in the High Energy Physics field, in which the Department has an active programme Duties to commence as soon as possible Salary scales Lecturer, £1,250 to £2,150 per annum, initial salary according to qualifications and experience, Assistant Lecturer, £1,000 to £1,150 per annum Membership of the F S S U and Children's Allowance Scheme

Applications should be sent not later than November 15, 1963, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained Applications by airmail letter in the first instance will be received from overseas candidates, who should state the names and addresses of at least three persons to whom reference can be made

---

POST-DOCTORATE FELLOWSHIPS UNDER the National Research Council of Canada, in the following fields—Physical Chemistry gas kinetics, combustion reactions by mass spectrometry, enzyme kinetics, radiation, induced polymerization, molecular structure by infra-red spectroscopy Organic Chemistry steroid hormones, synthesis and conformational problems Natural quinones, isolation and structure For particulars write to Paul A Giguère Director, Chemistry Department, Laval University, Québec 10, Canada

---

AUSTRALIAN NATIONAL UNIVERSITY
LECTURER IN BOTANY (GENETICS)

Applications are invited for appointment to a new post of Lecturer in Botany (Genetics) in the School of General Studies of the University The appointee will be required to take up duty as early as possible in 1964 An interest and experience in biochemical and/or physiological genetics is desired The salary range for lecturer is at present £A1,750 by £A100 to £A2,45 per annum Salary on appointment will be i accordance with qualifications and experience A cost of living allowance, at present £A31 per annum, will be paid to an appointee within the range, except at the maximum Salaries are under review

Further information and the forms which should accompany an application may be obtained from the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House Pall Mall, London, S W 1 Applications close i Australia and London on November 25, 1963

PILKINGTON BROTHERS LIMITED

Glass Manufacturers, require

PHYSICISTS

to work in the Models Laboratory of Technical Development on Studies of furnace design

The work involves the simulation of flows of molten glass and combustion gases using scale models, the designing of these models, planning of experiments and the supervising of assistant staff

The age range is 23 to 30 years and the successful applicant would probably have an honours degree in physics, but applicants with other appropriate qualifications and experience of fluid dynamics would be considered

Please quote M L /3 in applying to L P Laidlaw, Group Staff Department, Pilkington Brothers Limited, Grove Street, St Helens, Lancs

---

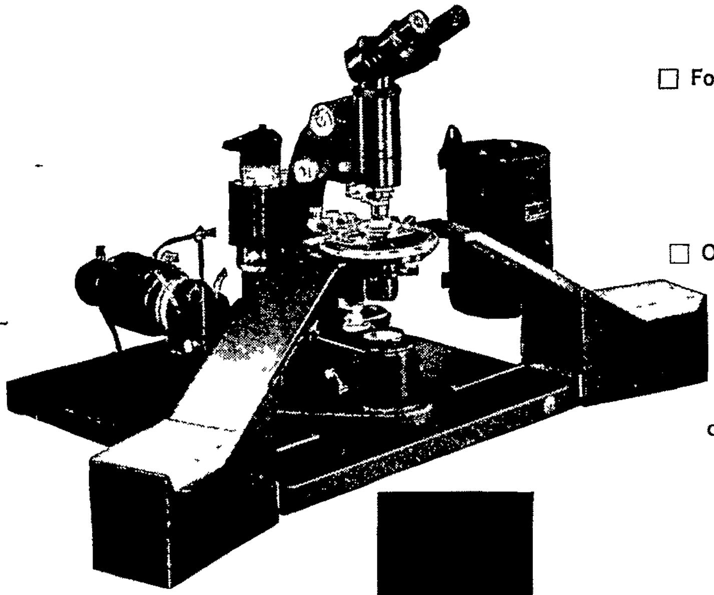
UNIVERSITY OF CAPE TOWN/ PROVINCIAL ADMINISTRATION OF THE CAPE OF GOOD HOPE/ JOINT MEDICAL STAFF
DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY
LECTURER IN PHYSIOLOGY

Applications are invited for a newly created lectureship in Physiology at a salary within the range R 2,040 to R 3,480 (£1,020 to £1,740) per annum, depending on experience and qualifications A medical degree or a higher degree in physiology or biochemistry is desirable Applicants should be prepared to assume duties on or soon after January 1, 1964 Applicants should state age, qualifications, experience, publications, and research interests, and give the names of two referees whom the University may consult

Two copies of the application must be sent to the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (from whom memoranda giving the general conditions of appointment, travel allowance on appointment, and further information about the department should be obtained), not later than November 11, 1963 A third copy of the application should be sent direct by airmail to the Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town South Africa, to reach him by the same date The University reserves the right to appoint a person other than one of the applicants or else to make no appointment

---

THE MEDICAL COLLEGE OF ST BARtholomew's Hospital, West Smithfield, E C 1 Applications are invited for the post of Junior Lecturer in Zoology tenable as from January 1, 1964, or as soon thereafter as possible The successful applicant will be required to assist in the teaching of medical students and to carry out research Preference will be given to a person interested in cytological or physiological aspects of vertebrate reproduction The salary will be on the scale £1,000 by £50 to £1,150 plus £60 London Allowance, together with Children's allowance and membership of the F S S U—Forms of application, which should be returned not later than November 18 may be obtained from the Secretary of the Medical College



LEITZ U.V. Micro Beam instrument

after Seidel

☐ For experimental work in general physiology, growth physiology, cytophysiology and cytogenetics.

☐ Irradiation of sites to be determined microscopically, with U V beams from $5m\mu \times 5m\mu$ to $250\ m\mu \times 250\ m\mu$

☐ Observation of the behaviour of cells after radiation damage or their reaction to certain wavelengths of the U V -range.

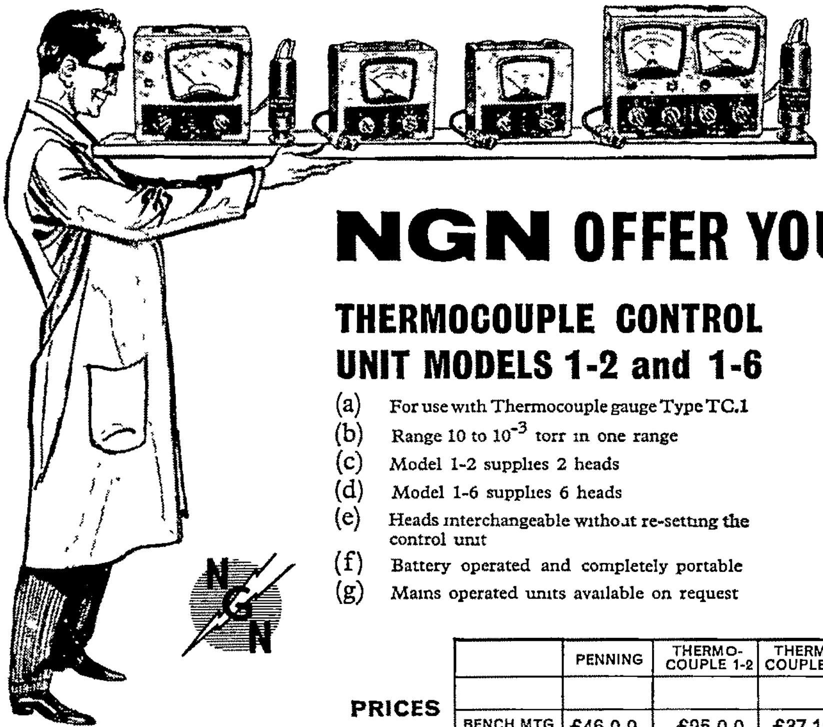
☐ Production of artificial pathogenesis.

☐ Artificial mutations through the irradiation of chromosomes in germinating or isolated cells, etc.

The Leitz production programme includes — Microscopes, Micromanipulator, fully automatic ORTHOMAT microscope camera, Photometer, Lecture hall projectors.

a Leitz product of thoughtfulness and skill

E LEITZ (INSTRUMENTS) LTD , 30 MORTIMER STREET, LONDON W.1.



NGN OFFER YOU

PENNING CONTROL UNIT MODEL 1

(a) Range 10^{-2} to 10^{-6} torr in two ranges

(b) For use with Penning gauge head Type PG 1

(c) Facility for external meter or recorder

THERMOCOUPLE CONTROL UNIT MODELS 1-2 and 1-6

(a) For use with Thermocouple gauge Type TC.1

(b) Range 10 to 10^{-3} torr in one range

(c) Model 1-2 supplies 2 heads

(d) Model 1-6 supplies 6 heads

(e) Heads interchangeable without re-setting the control unit

(f) Battery operated and completely portable

(g) Mains operated units available on request

THERMO-PEN CONTROL UNIT MODEL 1

(a) For use with Penning gauge Type PG 1 and two Thermocouple gauges Type TC 1

(b) Covers the ranges 10 to 10^{-3} torr and 10^{-2} to 10^{-6} torr

(c) Mains operated.

(d) Each circuit incorporates all the features of the above instruments

GRANT
INSTRUMENTS
CAMBRIDGE

JUNIOR THERMOSTATIC WATER BATHS

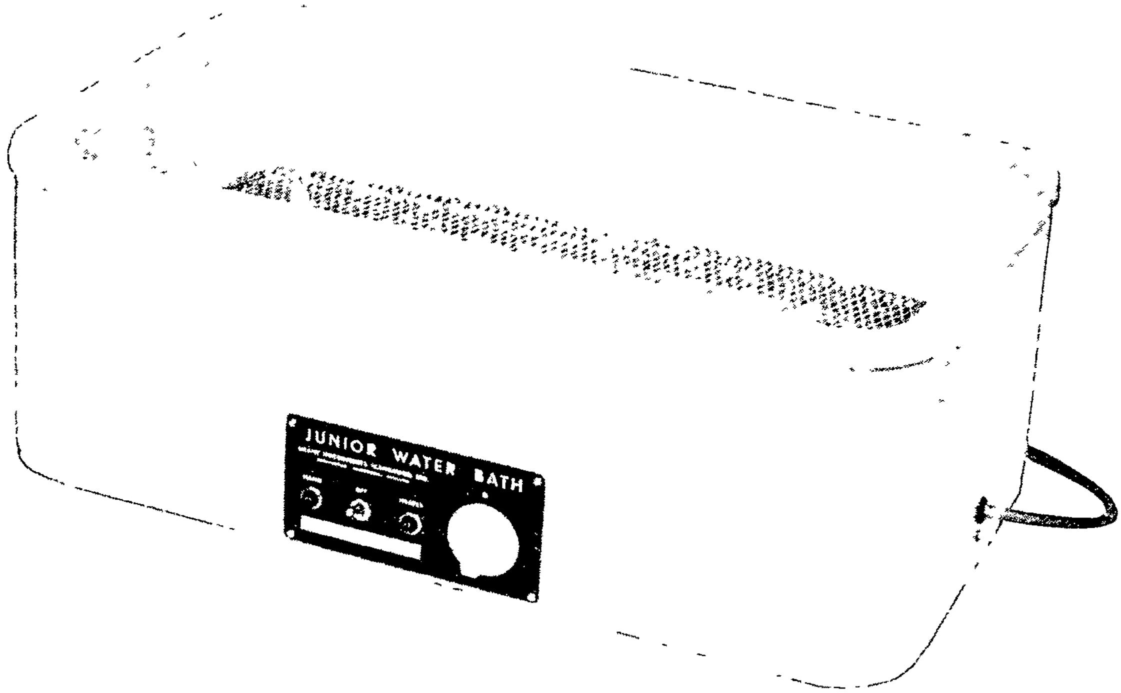
20–90°C ± 1°C.

***JB1* • *£12-10-0* • 12″ × 5″ × 4″ internal**

A new range of simple thermostatic baths with polypropylene tanks and stove-enamelled outer cases

A copper-sheathed immersed-rod heater and liquid-expansion thermostat are mounted under a perforated stainless steel tray. The thermostat has a calibrated dial, and neon lamps show "mains on" and "heater on". Fluctuations *inside* flasks or test tubes do not exceed ±0.2°C and differences between one flask and another are less than 0.1°C.

These baths are also available as boiling baths with energy regulator in place of the thermostat (or as well as the thermostat) A wide range of lids and other accessories can be supplied for the baths.



***JB5* • *£19-5-0* • 23″ × 13″ × 4½″ internal**

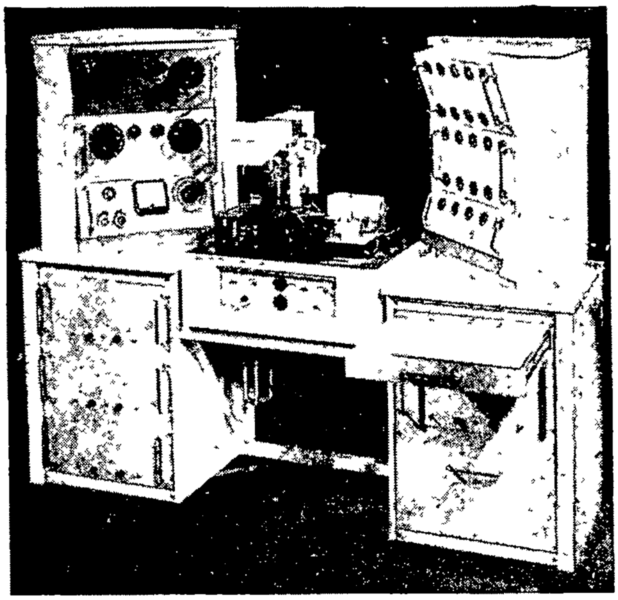
COUNTING AND SIZING MICROSCOPIC MATERIALS *Automatically*



Vickers Automatic Counters and Sizers take the tedium out of counting and sizing small particles, speed up the work, improve accuracy and release skilled microscopists from routine work. These instruments are being used to count and size inorganic powders and aerosols, using either the original material or shadows obtained by the evaporating aluminium technique They are also being used in cellular biological research, notably in the field of cancer and bacteriology.

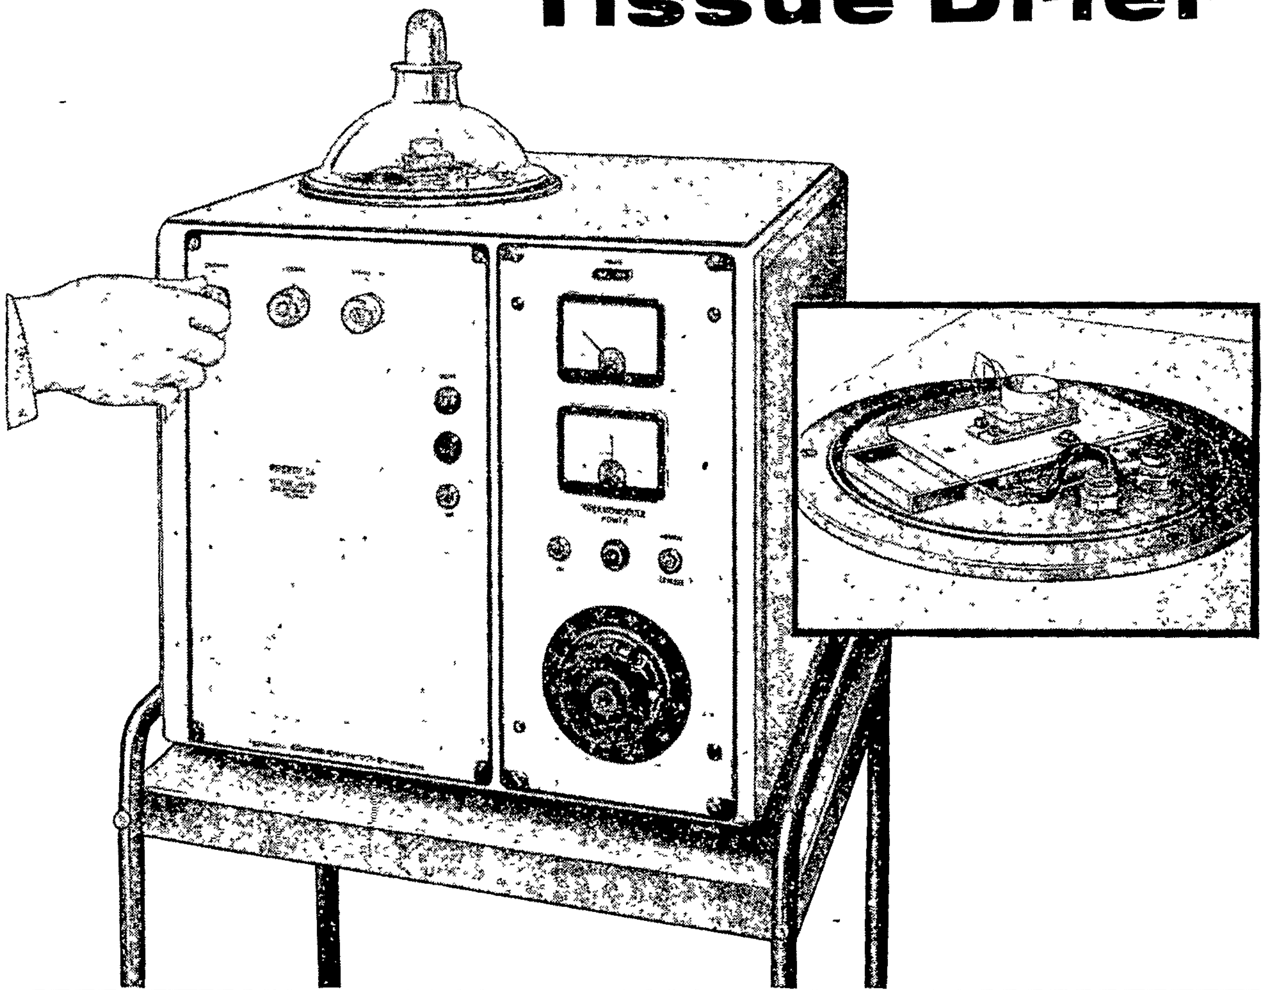
Scanning is by the wide track method. Using 200 scans of 10 mm active regions per scan, an area of 50 mm.^{2} is covered in 55 seconds with the Console model and in 60 seconds with the Bench model. The size range covered is approximately 1 0 to 200μ The machines will be demonstrated in our showrooms to suit your convenience. **A Bench Model is also available.** Send for Brochure.

VICKERS INSTRUMENTS LTD. Purley Way, Croydon, Surrey and Haxby Road, York

Successors to Cooke, Troughton & Simms Ltd and C Baker Instruments Ltd

Freeze dried specimens to embedded stage simply and cleanly . . .

"SPEEDIVAC"-PEARSE Tissue Drier



Convenient and easy to operate ● Rapid thermo-electric cooling to –60°C ● No freezing mixture required for the freeze-drying process ● Integral wax embedding facility—resin embedding accessory ● Specimens heated to embedding temperature by the same thermo-electric element ● Mechanical interlocks prevent mal-operation of thermo-electric element ● Rapid pump down to better than 0·01 torr (mm Hg) ● Gas ballast rotary pump safe from moisture contamination ● Direct observation of temperature and chamber pressure

"Speedivac" products and service are available internationally

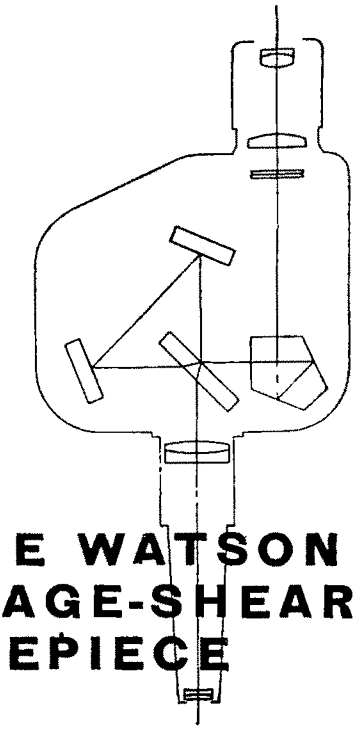
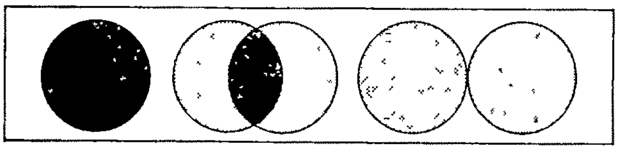
WATSON

FOR EASE AND SPEED OF SIZE DETERMINATION



THE WATSON IMAGE-SHEARING EYEPIECE



THE W.I.S.E. WILL PROVE INVALUABLE FOR

Particle size analysis

Diameter measurement of fibres, synthetic fibres, spun yarns, wires

Measurement of transistor components and photographic masks

Measurement of many biological specimens and bacteria

Dust control

Measurement of diamond pyramid indents in hardness testing

THE W.I.S.E. OFFERS YOU

A high degree of light transmission—it can be used for projection

Versatility—the majority of microscopes will accept the W.I.S E.

Exceptionally quick, easy and accurate read-out from the combined counter and drum of the setting head

In the Watson Image-shearing Eyepiece, shearing is achieved by means of a dichroic beam splitter which gives colour differentiation of the beams with less than 3% light loss due to absorption. The shear is proportional both to the movement of the two mirrors in the system and the adjustment of the setting head from which readings are taken. The use of filters is normally unnecessary; a polarising filter may be used, however, to restore colour balance where specimen staining interferes with relative image strength. The W.I.S.E. will fit most microscopes possessing RMS standard tube diameter, and direction of shear can be altered simply by turning the Eyepiece in the microscope tube. A graticule indicates direction of shear and defines a standard area for particle counting. For size distribution studies the W.I.S.E. can be pre-set and calibrated if required Overall magnification with the standard eyepiece supplied is x20.

If you would like to know more about this outstanding new instrument, please write for full details to

KODAK

High Speed Ektachrome – fast becoming invaluable in many research projects...

High Speed 'Ektachrome' is the fastest colour film made by Kodak. Rated at ASA 160, it brings black-and-white speed to colour photography. It has proved itself invaluable where coloured dyes are used as markers; in metallurgical analysis by flame propagation; in photo-recording where high-speed galvanometer traces overlap and need to be identified by colour; in photo-elastic stress analysis; in Schlieren photography and in many other fields where high speed transients and identification by colour go together.

Write for details.

LIBRARY SERVICES AND THE SOURCE FOR INSPIRATION

IN the *Returns from Universities and University Colleges in Receipt of Treasury Grants, Academic Year 1961–62*, the University Grants Committee continues its recent practice of including a general survey of the year. Prominence is given in this survey to the appointment last June, with the Ministry of Education, of a Library Committee, the terms of reference and the membership of which are set forth. Both terms of reference and the membership have been the subject of some criticism, and the importance of the university library has been stressed in some recent discussion of university education. It has, indeed, been urged as one reason for concentrating the university expansion on existing large universities that only such universities have any prospect of providing the essential library resources on an adequate scale.

It might be commented in this connexion that past and present parsimony has put almost all Britain's existing university libraries far behind the university libraries of the United States in their resources, nor do the returns included in the present report from the University Grants Committee indicate any improvement or prospect of improvement. Library expenditure in Great Britain as a whole remains at no more than 3·8 per cent of university expenditure as compared with 3·8 per cent in 1951–52 and 4·0 per cent in 1959–60, and the total expenditure is now only £2·8 million compared with £988,000 in 1951–52 and £2·35 million in 1959–60. The total expenditure on books is little more than £600,000 a year and on periodicals a little more than £300,000; the combined expenditure of all the universities for these purposes is only £640,000 and £330,000, respectively. Only at the University of Oxford does expenditure on books approach £100,000 a year, and at the University of Cambridge £50,000 a year, and only at eight other universities does it approach or exceed £20,000, apart from London. Only some half-dozen universities spend £15,000 on periodicals, and the combined expenditure of £330,000 compares with £118,000 in 1951–52.

These figures are pertinent in that the new Library Committee is instructed "to consider the most effective and economical arrangements for meeting the needs of the Universities and the Colleges of Advanced Technology and central institutions for books and periodicals, taking into account expanding staff and student populations, the possible needs of other users, the growth of research, the rising costs of books and periodicals, and the increasing capital cost of library accommodation". There is manifestly much past neglect and parsimony to be made good at costs which will be inevitably the higher for delay. It is to be hoped the lesson has been learned.

The Committee was also "to assess how far greater use might with advantage be made of shared facilities, both between the institutions themselves and between the outside library systems and other institutions, and of modern methods of reproduction". If this part of its terms of reference implies recognition that university libraries are an essential part of a national library system, that may explain to some extent the membership of the Committee. It will scarcely explain some of the omissions, and it is manifest to anyone who has the slightest acquaintance with library organization in Britain as a whole why the Committee, as at present constituted, fails to command confidence, respect and enthusiasm, not only among the staff of the university libraries but among the Standing Conference of National and University Libraries, the National and University Libraries Committee of the Library Association or the Association of Special Libraries and Information Bureaux. Such confidence and respect are essential, however, if the Committee is to prove effective, and there is little in its present membership to offset doubts as to its possessing either the professional expertise and insight or the imagination and drive which its work demands.

The most appropriate background against which the work of this new Committee is to be assessed is, however, provided by the forthright address which Dr. J. N. L. Myres, the Bodley's Librarian, delivered as president at the annual conference of the Library Association on July 7. Dr. Myres quoted a comment from Mr. R. Vosper, of the University of California, that Illinois, with 3·5 million volumes, was the largest State university library in the United States and the only one that had undertaken to compete with Harvard in the massive and persistently expanding support that is essential to library excellence. He asserted that unless Britain's university libraries, both new and old, were given this massive and persistently expanding support and had the priority over other university needs, which Mr. Vosper also claimed was so at Illinois, there was no possibility in the present acutely competitive condition of the international book trade that they would achieve or retain the value or the status necessary to make their universities worthy of the name. It is not simply a question of money, though the figures already quoted indicate sufficiently how poorly placed are the university libraries of Britain to compete with the effect which this massive American buying of older books and manuscripts has had and still is having on the dwindling sources of supply in Europe or on the general level of prices. Dr. Myres was thinking far more of the need for consistent and sustained generosity in providing library funds and of the overwhelming and urgent need for a far higher level of financial support for learned libraries generally in Britain.

Dr. Myres began his consideration of the position of the university or learned library by referring to the challenge presented to statesmanship in the policy to be adopted in providing libraries for the new and recently created universities—a challenge which he urged confronted not only the newly appointed librarians and library authorities, but no less their vice-chancellors, the University Grants Committee and the Treasury. Dr. Myres thought that there was grave risk that, in spite of apparently generous initial grants, the assumption might be made that the main requirement was to provide for the current needs of undergraduate study with a limited range of standard text-books, periodicals and works of reference, and that, for anything outside that range, recourse should be had to the borrowing facilities already available either regionally or nationally from older and better stocked collections. Admittedly these new university libraries will require all the assistance they can obtain in their early years from outside sources, and may take many years to create for themselves even the basic minimum stock which will justify their existence as learned libraries

Even if Dr Myres is a little pessimistic as to the time required for that purpose, he is fully justified in his assertion that the notion that the needs of these libraries beyond a certain point ought not to be satisfied permanently, or for a moment longer than is absolutely essential, by reliance on borrowing from existing libraries, even from national loan collections such as the National Lending Library for Science and Technology or an equivalent institution in the humanities that may be created, is a dangerous delusion Dr Myres does not decry or minimize the value of such facilities He insists, nevertheless, that such facilities should never be regarded as an adequate substitute for the possession on the spot of books that are needed on that spot Moreover, no university library worthy of the name will ever be formed on the principle that anything it requires but does not possess need not be bought if it can be borrowed from elsewhere

That principle needs assertion to-day and not simply in relation to the expansion of existing or the creation of new university libraries but in regard to the development of an efficient and economically sound national library system It is of the first importance that the new Library Committee should bring home to the University Grants Committee that the only sound policy for a university library, on grounds of economy no less than efficiency, is one that aims at providing within its own walls its own copies of everything which the members of the university need for the promotion of their own studies or the advancement of learning. Reasons of space or scarcity may impose the use of modern copying methods in place of originals, but that does not invalidate the principle, and clear thinking on this point is a first essential

But the principle reaches further and it is two-edged University libraries are important participants in the National Central Library's present system, and most university librarians can tell of requests for the loan of books and other publications the cost of which is sometimes no more than that of the postage and packing involved Government departments are notorious offenders in this respect, and unless a sense of proportion obtains and due vigilance is exercised, efficient loan systems could founder through unreasonable demands There is already some concern over the policy adopted by the National Lending Library for Science and Technology, and this uneasiness was not removed by the talk which Miss Webb gave to Aslib last May on the new National Library of Science and Invention, of which she is to be in charge

The new Library is to restrict its holding of periodicals to those less than 50 years old, the old volumes being transferred to the British Museum Library or to the National Lending Library for Science and Technology With the discontinuance of a loan service from the remains of the Science Museum Library in London, access to the older periodicals, particularly open access, will be considerably more limited or impeded This may be a serious matter for those working on the history of science, and it has its bearing on the extent of the stocks which a university library should hold and on the validity of a policy based on the alleged fact that a periodical article is only consulted once on average Averages are misleading and even worthless where the scholar is concerned even if the basis of compilation is not open to challenge The only sound basis for determining policy as regards stocks of older periodicals and books, whether for loan or access, is in relation to a national scheme which takes full account of the resources of all national institutions, including those of the learned societies and universities, as well as of the public libraries One cannot, for example, at the same time assert that insufficient use is made of existing knowledge and claim that the present records of use are necessarily a sound guide to future requirements

Dr Myres, in the concluding part of his address, was particularly concerned about the acquisition of research material in the face of American demand and resources It was the situation there that led him to conclude reluctantly that there was no will, in the quarters that control Britain's policy on the finance of higher education to provide the support which alone can build new university libraries worthy of the name, or enable the older ones to maintain their proper status in the world of learning, but there is little evidence to suggest that his fears generally are unjustified The unwillingness of the University Grants Committee to earmark grants for library purposes for fear of interfering with academic freedom is scarcely justifiable to-day, and if the appointment of the new Library Committee means anything it should point a way around that difficulty Certainly, while Dr Myres was urging the Library Association itself to use some of its own influence to impress those responsible for public policy in this matter, his words should not escape the attention of either the new Committee or the Minister for Science himself

Nor is it simply a matter of books and of buildings and equipment Of vital importance to the quality of the service given by a university library is the ability of its staff from the librarian downward The grounds for disquiet are no less substantial here While in the statutes for the new University of Strathclyde (see *Nature*, **199**, 1137, 1963) the university librarian is given the status of professor and a place on the Senate, only a handful of universities as yet accord such recognition to their librarian The scales advocated by the University Grants Committee are honoured in the breach rather than in the observance Even if the university librarians generally were placed in the professorial grade with the appropriate salaries, many of them would still find it almost impossible to attract and retain staff of the appropriate ability and enthusiasm in the existing salary situation—a position which, it should be noted, is equally characteristic of much of the public library service

A satisfactory library service for the universities and for the nation generally depends in some measure on a more generous and enlightened attitude to the librarians and their staff As part of such a policy, a more rational attitude may well be required to the organization of library work so that specially trained or skilled staff is not wasted excessively on duties which require no special professional knowledge or aptitude Here, the responsibilities of professional bodies are involved and they have essential contributions to make, and for that reason alone the Minister of Education can scarcely allow difficulties over the reorganization of local government to delay indefinitely the action which was recommended more than four years ago in the Roberts Report on the *Structure of the Public Library Service in England and Wales* (see *Nature*, **183**, 1289, 1437, 1959) Two reports have since been submitted to him, one on *Inter-Library Co-operation* *in England and Wales*[*] and one on *Standards of Public Library Service in England and Wales*[†], each by a working party set up to examine the technical implications of the Roberts Report

The report concerned with standards scarcely requires discussion here, though it should be noted that this working party stresses the need for an objective approach to the public library and its duties and once again emphasizes the importance of the public library as a great and developing national asset This conception is fundamental to any adequate survey of the functions which public libraries should be expected to perform and to any reasonable national library system, of which such libraries form an essential part Further, the working party recommends specifically that the public library should work in close association with the libraries of local technical colleges and of other educational institutions and with specialized libraries in other organizations It should be obvious, too, that the standards recommended by the working party on the grounds of library efficiency should contribute also to the effectiveness of the inter-library co-operation in England and Wales with which the second working party was concerned

The report of this working party recommends first that the existing eight regions of the library service should be reduced to four or five, each self-sufficient in certain types of material, and the Minister of Education, Sir Edward Boyle, indicates in a foreword dated December 1962 that he is asking the proposed advisory councils for England and Wales to consider the most appropriate relation between the English and the Welsh regions The report also recommends the replacement of the National Committee on Regional Library Co-operation by a joint committee appointed by these proposed Advisory Councils and reporting through them on all aspects of library co-operation It is also recommended that the regional councils and the National Central Library should consider the extent to which the holdings of university and other special libraries should be incorporated in regional catalogues as well as at the National Central Library

It is in respect of the National Central Library that the report touches more particularly on those aspects of a national system that are of most interest to the university librarian or to the scientist, and it is here also that some dissent is recorded by members of the working party The working party visualizes public library authorities as being made responsible in the foreseeable future for 30 per cent of the expenditure of the National Central Library It recommends consideration of the possibility of transferring responsibility for the Government grant to the Library from the Treasury to the Minister of Education as well as that the estimates of the Library should be prepared tri-annually The last proposal seems sound, but the idea that responsibility for the Library's financial resources might be placed alongside that for the National Lending Library for Science and Technology or the new National Library of Science and Invention does not appear to have been considered

There is, however, a logical argument for that course pointing, moreover, to the Minister for Science, and in line with this is Mr F G B Hutching's note of dissent regarding the cost of the National Central Library, the whole of which, in his view, should be met by the Treasury He rejects the suggestion of the earlier Roberts Report that half the income of the National Central Library should come from sources other than the Treasury, pointing out that the Library is primarily a means by which books throughout the country are made available outside their locality The closest analogy is not with the National Library of Scotland, as the Roberts Report suggested, but with the National Lending Library for Science and Technology, which is entirely supported by Government funds Mr D T Ricknell also insists that financial responsibility for developing the work of the Library should lie with the Treasury and adds that the whole service provided is national in character and its further development should be regarded as a national responsibility

These notes of dissent seem to be reinforced by the working party's finding that no case has yet been established for a new National Lending Library for the Humanities to undertake work which would be mainly an extension of what the National Central Library is already doing It recommends instead that the resources of the National Central Library for the purchase and storage of books should be considerably increased to enable it to remove many of the difficulties of research and supply in the field of the humanities The position would clearly be improved by a more generous policy in regard to university libraries generally, both in respect of the service which they are able to render to the members of their own community and the co-operation they are able to offer the National Central Library itself

Meanwhile, these reports substantiate essentially Dr Myres's plea for some more generous and realistic policy towards the university libraries both as such and as part of an adequate national system They indicate the weakness of attempts to deal piecemeal with the system and the extent to which the responsibilities of the Minister of Education in this field are interlocked with those of the Minister for Science That point emerges very clearly also from the background paper on science, economic growth and Government policy presented to the Ministerial Meeting on Science in Paris, as indeed in the report on *Science and the Policies of Government*, which was prepared by the Advisory Group on Science Policy of the Organization for Economic Co-operation and Development for the same meeting (see *Nature*, 200, 199, 1963) The importance of the work of the Library Committee appointed by the University Grants Committee and the Ministry of Education could not be better demonstrated, and in this context the Minister for Science may well be expected to take an even greater interest than the Minister of Education

BIOLOGY OF THE SEAS OF THE U.S.S.R.

Biology of the Seas of the U S S R
By Prof L Zenkevitch Translated by S Botcharskaya Pp 955 (London George Allen and Unwin, Ltd , 1963) 160s net

THE oceanic coasts of the U S S R are washed by Atlantic, Arctic and Pacific waters This vast country also surrounds, wholly or in part, the greatest and the most interesting and productive of all brackish water and inland seas the Baltic, Black Sea, Sea of Azov, Caspian and Aral Seas No other country has direct interest in seas so widely distributed or so diverse in salinity Apart from the Baltic, the Barents Sea, the Sea of Japan and the Bering Sea, in all of which other countries have made and continue to make major contributions, investigation of this large section of the seas of the world is entirely in the hands of Russian scientists working at 44 institutes and from more than 20 research vessels

[*] Ministry of Education *Inter-Library Co-operation in England and Wales* Report of the Working Party appointed by the Minister of Education in March 1961 Pp v+34 (London H M S O , 1962) 3s net

[†] Ministry of Education *Standards of Public Library Service in England and Wales* Report of the Working Party appointed by the Minister of Education in March 1961 Pp vii+124 (London H M S O , 1962) 7s net.

In this magnificent book, described in his preface as "a considerably amended and supplemented version of the second edition of my book *The Fauna and Biological Productivity of the Sea*, published in 1947", Prof L Zenkevitch reveals how great are the contributions which he and his fellow workers have made to the science of oceanography These enable him to paint a comprehensive picture of the conditions of life and the factors controlling productivity in the 13 seas to which he gives separate consideration The Russian approach to biological oceanography has always been quantitative As an inevitable consequence of the vast areas with which they are concerned, they have had to pay initial attention to the wood as a whole, leaving detailed consideration of the individual trees until later It is the biomass of plankton, of invertebrate benthos and of fishes and the controlling effect of regenerated or inflowing nutrients which form the dominant and always fascinating themes of this book

The subject-matter is divided into northern, southern and far-eastern seas In each a preliminary account covering general characters is followed by chapters dealing with the individual seas History of exploration is followed by descriptions of geology, including submarine topography, hydrography, the nature and origin of the fauna and flora and productivity in terms of plankton and benthos, leading finally to consideration of commercial fisheries

In the northern seas we begin with the Barents Sea with its rich fauna of mixed Atlantic and Arctic origin and great productivity associated with the vertical mixing of its waters along the polar front We then progress eastward by way of the White, Kara, Laptev and Chukotsk Seas By stages the influence of the Atlantic is reduced both qualitatively and quantitatively—in the White Sea the average benthic biomass drops to one-fifth The less-saline waters of the Kara Sea contain a unique high Arctic relict brackish water fauna Finally, incursion from the Pacific comes to influence the fauna of the Chukotsk Sea An admirable account of the Baltic concludes these descriptions of northern seas

The southern seas are the enclosed seas and also those least known outside the U S S R No marine or fresh-water biologist, indeed no biologist interested in the effect of environment on life or on the distribution of living things, can fail to find matters of compelling interest in these chapters on the Black Sea Sea of Azov, Caspian and Aral Seas In his introductory chapter, Prof Zenkevitch traces the history of these inland seas and the origins of their fauna and flora To a relict community of marine Tertiary origin, much influenced later by exposure to fresh waters, have been added immigrants from fresh waters, from the Arctic and, more significantly in the Black Sea and Sea of Azov, recent invasions from the Mediterranean Although impoverished these faunas may be immense With a mere fraction of the faunal variety of the Mediterranean, the Sea of Azov has a far greater productivity

Even in the Black Sea, despite lack of oxygen in its depths, a postulated vertical circulation implies far greater productivity than has been suspected In the Caspian the immense inflow of nutrients especially from the Volga has been more fully utilized in terms of eventual production of fish by the deliberate introduction of *Nereis diversicolor* (not *N succinea* as originally thought) and other benthic invertebrates Mussels, barnacles, diatoms, fish and prawns, even a medusa and a crab from America, have all of recent years found their way into these receptive waters

The final section, dealing with the Sea of Japan, Sea of Okhotsk and the Bering Sea, has been added in this edition Here we are in the richest as well as in the deepest ocean Zones of benthic life are considered from the supralittoral to the profound depths of the Kuril-Kamchatka Trench The greater speed of growth of the Pacific, as compared with the Atlantic, cod is related to the much richer benthos and also to the shorter migrations between feeding and spawning grounds The densest populations of herring in the world occur in the Sea of Japan where, after the milt has been shed, the waters are smoothed as though oil has been poured on them Perhaps the richest of all feeding grounds for demersal fish and crabs lie on the western Khamchatka shelf The existence of an amphi-boreal fauna of recent origin can "be considered", Prof Zenkevitch writes, "as an immense experiment in acclimatization by Nature herself—a conquest of vast new habitats, often more spacious than the original ones" It is an experiment which is being emulated by Soviet biologists responsible for movement of Pacific salmon and crabs to north Atlantic waters

No short review can do anything approaching justice to this book, which opens windows on to such wide prospects of scientific knowledge It is written by a complete master of the subject and has been extremely well translated by Sophia Botcharskaya, there is only one obscure passage near the bottom of p 101 It contains 427 most illuminating figures with 329 tables, and concludes with some 50 pages of references and an excellent index I would regard this as the most important book on marine biology since the publication in 1912 of Murray and Hjort's *Depths of the Ocean* C M YONGE

MORE DEVELOPMENTS IN PLANT ANALYSIS

Moderne Methoden der Pflanzenanalyse

Begründet von K Paech und M V Tracey Fortgeführt von H F Linskens und M V Tracey 6 Band unter mitarbeit von B D Sanwal Bearbeitet von verschiedenen Fachgelehrten Pp xxiv + 512 (Berlin Springer-Verlag, 1963) 98 D M

THIS volume is the second of the supplementary volumes in the series *Modern Methods of Plant Analysis* As evidence of its quality, it is sufficient to say that it maintains the high standard set by Volume 5 The present number includes an extensive section on the general methods of enzyme chemistry, in which the new editorial combination of H F Linskens and M V Tracey was assisted by B D Sanwal In all, there are 24 separate articles, 14 in German and 10 in English

Some of the articles, although useful, require little comment since they are essentially extensions to the range of compounds covered in the earlier volumes Thus, W Heinen deals with silicon compounds, H Stern with the determination of sulphydryl groups, U Beiss with phosphatides and glycolipids, F Bohlmann and W Sucrow with naturally occurring acetylene compounds, and M Hesse and H Schmid with natural chromones Other articles deal with products characteristic of individual species or plant groups Thus, R Braun describes the production, isolation and quantitative determination of orchinol, an antibiotic formed by the tubers of a number of orchid species following incubation with the fungus *Rhizoctonia repens*. An article by J R Hudson deals with the humulones, lupulones and other constituents of hops S Shibata gives a comprehensive account of lichen substances, illustrated by 6 photomicrographs of crystals of lichen acids R Braun contributes an account of the toxins produced in plants by pathogenic micro-organisms, and J Tobiška deals with phytoagglutinins F Zilliken and R Lambert describe the isolation and analysis of bacterial cell walls

In the section dealing with enzymology, there are articles by W. Heinen on the detection of enzymatic activity and on the general characterization of an enzyme, by W. Heinen and H F Linskens on the Thunberg technique, by B D Sanwal on general methods of preparation and on enzymatic assays of amino-acids and keto-acids, by H G Boman and W Bjork on general aspects of enzymatic purification and characterization, by H G Boman on the purification of enzymes, by F Bendall on the inhibition and activation of enzymes, by G Pfleiderer on the enzymatic determination of metabolites, and by E Hofmann on the analysis of enzymes in soil Individual groups of enzymes are dealt with in the next volume, No 7 in the series

As in the previous volume, certain articles will be of special interest to many plant physiologists In his account of kinetin and kinetin-like compounds, C O Miller discusses the merits of the various bio-assay systems available An article by R Knapp on gibberellins includes accounts of their chemical properties, of their occurrence in plants and of the chemical, physico- chemical, and biological methods available for their detection

There is little need to stress the great value of this volume, and indeed of the entire series, to those concerned with almost any aspect of plant analysis All the favourable comments made in the earlier review of Volume 5, about the printing and general production of the book, apply equally to the present volume

A Allsopp

POLYCHAETE PHYSIOLOGY

Annelids

By R. Phillips Dales Pp 200 (London Hutchinson and Co (Publishers), Ltd, 1963) 15*s*

This book does not live up to the expectations of its title which could, with minor deletions, have been, more appropriately, "Aspects of the Physiology of Polychaetes"

Following a comprehensive introduction there are nine chapters, the first treating the general organization of the body with a proper emphasis on segmentation, and on the origin and fate of the cœlom and mesodermal tissues Thereafter there follow seven chapters, which, though sufficient in their coverage of polychaete physiology and reproduction and development, pay but lip-service to the existence of any other group of Annelida or other branches of zoology

If Chapter 3 on the evolution of polychaetes is aimed at the student population it can have but scant appeal If students can make their way through the maze of family group names they will deplore the absence of substantiated fact What is the point of telling them that the goniadids, the Sphaerodoridae and Pisionidae are derivatives of Nephthydidae and Glyceridae without, at least, extensive morphological comparisons, with the aid of diagrams, in view of the total lack of supporting embryological and palæontological evidence? This type of ill-considered assertion is repeated throughout this chapter Indeed, if a chapter on the evolution of Polychaeta is necessary—which I doubt—it is incorrect to say, "there are no fossils worth mentioning" Very large populations of polychaete jaws are known from the Ordovician and the great variety of the polychaete fauna of the Cambrian Burgess shales, and the information on the past history of the group these provide should have been mentioned

Chapter 9 deals with the origin and classification of the oligochaetes and leeches Presumably this is to make up for having given them comparatively little attention previously Students should note that the body of a leech is made up of 34 segments, 7 of which contribute to the ventral anal sucker, not 33 and 6 as on p 181. Reference is made in this chapter to the excellent and comprehensive text-book by K H Mann, *Leeches* (Pergamon Press, 1962), as a source for the identity of British leeches, and readers should know that this work in fact provides a key for the identification of genera of marine leeches throughout the world and species of fresh-water leeches from central Europe, Britain and North America

A surprising omission is that no chapters have been included on distribution, either ecological or zoogeographical Much recent and comprehensive work on marine pollution, encrustation, and zonation together with extensive soil and forest-fauna surveys have thus been overlooked, which would have been welcomed by student and research worker alike.

Yet, perhaps, the major omission is that the important chromosome studies by Omodeo and Muldal on lumbricid earthworms have been reduced to a nebulous sentence of some nineteen words (p 179) and their respective works not even included in the bibliography Finally, the one other place where reference to chromosomes appears (p 182) refers briefly to the leech work by Wendrowsky, which is also omitted from the bibliography

N. Tebble

AN OUTLINE OF HISTOCHEMISTRY

Histochemistry

Theory, Practice and Bibliography By Tibor Barka and Paul J Anderson Pp x + 660 (New York and London Hoeber Medical Division, Harper and Row, Publishers, Inc, 1963) 18 50 dollars

The authors have set out to provide a general outline of histochemistry, a concise practical and theoretical guide to histochemical methods, and a detailed bibliography of methods and their applications The bibliography is fairly extensive, consisting of almost 5,000 references, and in fact forms more than one-third of the whole book With the rapid growth of the subject this cannot fail to be of great value to workers in the field of histochemistry

In the early part of the book the general techniques for preparation of tissue are surveyed, and cryostat, freeze-drying, and freeze-substitution methods are described In the case of the cryostat it is stated that "serious morphological alterations are always encountered" (p 7) In spite of this, in the section devoted to demonstration of succinic dehydrogenase, an enzyme confined to mitochondria, it is stated that "cryostat sections of fresh tissue are necessary for the histochemical reaction" Moreover, it is known that cryostat sections can be regularly prepared in which neither mitochondria nor lysosomes show evidence of morphological damage (Bitensky, L, *Brit J Cancer*, 14, 696 (1960), *Ciba Found Symp on Lysosomes*, 362, Churchill, London, 1963) The authors realize that in histochemistry a critical attitude is necessary, but no indication of the particular standards is given In discussing the methods for hydrolytic enzymes, it is surprising that only passing reference is made to the work of De Duve, that it only relates to acid phosphatase, and fails to mention the importance of the lysosome with reference to all acid hydrolases On p 205 a list of factors which may interfere with the demonstration of a particular enzyme is given Yet, on p 238 in the section dealing with acid phosphatase, techniques are recommended that result in at least 50 or 60 per cent inactivation of the enzyme If strict criteria are to be observed, then such methods should surely be regarded as useless Again, on p 238 it is stated that "their demonstration (i e, acid phosphatases) in cryostat sections is unrealistic, even if hypertonic or 'osmotically protected' incubating solutions are employed" Other workers have found that localization of acid phosphatase can be constantly demonstrated within the lysosomes in cryostat sections of normal tissues which have been suitably treated.

In a work of this kind, which is presumably intended to encourage workers in histochemistry, it is disappointing to find that the authors regard the subject in such a narrow fashion. It would appear that their initial approach is purely morphological, and that is certainly no disadvantage. When it is stated that "deriving its theoretical foundations from chemistry, histochemistry remains a morphological tool" (p. 342) one feels that the extensive possibilities of the subject remain unexplored by the authors. This is decidedly surprising for much attention has been directed to the demonstration of enzymes which are essentially dynamic in nature. Again on p. 342 they say that "finite measurement is not the immediate goal of microscopic histochemistry". The large number of biochemical comparisons made in recent years between normal and abnormal tissues have served to emphasize that while qualitative differences do exist they are greatly outnumbered by quantitative variations. It is hard to see how these differences can be identified if quantitative histochemistry is not developed. Biochemistry has done much to advance our knowledge of the cell, but a precise localization of chemical components can be achieved only by histochemical methods. Whether the method of study be the demonstration of carbohydrates, lipids, proteins, or enzymes, or the rate of uptake of labelled metabolites, the aim is the same, namely, to piece together our information on the metabolism of the cell. At the present time it is too much to hope that one discipline will provide the answer to any one problem, but it is quite certain that histochemistry in its future and fuller development will play a vital part in the understanding of cellular physiology and pathology. It would indeed be sad if it merely demonstrated a number of new structures, the function of which could not be determined.

GEORGE J. CUNNINGHAM

VIRUSES

Advances in Virus Research

Vol. 9. Edited by Kenneth M. Smith and Max A. Lauffer. Pp. viii + 312. (New York and London: Academic Press Inc., Publishers, 1962.) 92*s*.

ONE-THIRD of this number of *Advances in Virus Research* is occupied by an article by St. Groth called "The Neutralization of Viruses". The article is in fact more limited than this for it deals almost exclusively with the influenza viruses. This makes it rather specialized, but it is written in a lively and colourful manner so that the reader is carried along in the stream in spite of possible disagreement with many of the *obiter dicta*. The influenza viruses are an admirable vehicle for carrying the general argument for they have an unusual number of measurable activities—infectivity in several hosts, toxicity, an enzymic activity, and hæmagglutination—all of which are inhibited by suitable antibodies. St. Groth discusses the peculiarities and limitations of each type of measurement, the effects on them of virus and antibody heterogeneity, and, when possible, the mechanism of the action. Wisely, each section is followed by a summary so that the reader unfamiliar with work of this type can keep track of what he has been told.

The scope of the article by Porterfield on the arthropod-borne viruses, that is the viruses that can multiply in both mammalian and arthropod hosts as distinct from those that are transmitted mechanically by arthropod hosts, is somewhat similar. The article is factual rather than interpretative; it shows the complexity of the antigenic structure of the viruses and the variation in the hosts' responses to them. Non-specialists would have understood the article more fully if the editors had explained the terminology, especially the system of units used. It ends with the comforting conclusion that there is no good evidence for the appearance of new viruses in this group though the antigenic components may regroup in suitable conditions.

The causative agents in a group of clinically rather ill-defined infections of the respiratory tract, and of some organs in the abdomen and elsewhere, in man and animals are grouped together as the adenoviruses. Electronmicrograms of several members of the group show icosahedrons with rounded corners. Brandon and McClean discuss both the structure of the virus particles and the reactions of the infected host to them. The story is fascinatingly complex with a cytopathic protein made by the infected host, at least three antigens that seem to be fragments of the intact virus and, in long-established infections, intranuclear crystals that seem to be virus aggregates. As the authors point out, this multiplicity of effects makes the group peculiarly suitable for an investigation of the general nature of virus infection.

The article by Smith is more general in scope. He gives a great deal of information on what might be called the natural history of the arthropod viruses and shows that many of the old ideas about them are ill-founded. They are by no means as host-specific as used to be thought, several can multiply in both insects and plants and cause pathological changes in both hosts, and latency is so widespread as to render all claims for the chemical induction of new virus infections suspect. The last phenomenon is particularly interesting because an uncongenial environment, or even a change of diet, can make the latent virus patent. There seem to be no general differences in morphology or chemical composition between arthropod viruses and those of plants or mammals, but the arthropod host seems able to tolerate an unusually large amount of virus before it finally succumbs—the only analogies with this extensive replacement of host tissue by virus is found in some of the infective mammalian warts, and in nitrogen-deficient plants.

Markham contributes a cheerful article on the information that can be gained about viruses by ultracentrifugation. He stresses that the instrument is easy to use, the calculations easy to make, and that a great deal can be found out with even one run on unpurified material. There is much shrewd and entertaining comment here. Those who were engaged in the early work on tobacco mosaic virus assumed that linear aggregation would have little effect on sedimentation constant; they will therefore be surprised to learn that the fact that this is so is unexpected.

Ten years ago, few virus workers could tell a regular from a rhombic dodecahedron; but we are all Platonists nowadays and the icosahedron is our juju. The significance of the regular solids (or the helix) is, however, widely misunderstood. These structures are likely to be common because they offer unusual opportunities for the formation of a stable shell. Speaking anthropomorphically, for the sake of brevity, the two main problems confronting a virus are: to find a system in a host that can be deluded into synthesizing virus, and to be stable enough to avoid the host's scavenging systems. We may therefore expect certain structures to appear often, as caffeine appears in at least 14 families of plants and the benzene ring (probably) in all organisms, though it serves many purposes and is made in many different ways. That is a reaction to the final article, by Andrewes, on the classification of viruses. We classify from a point of view and with an end in view. At one point Andrewes agrees and says "taxonomy is an artificial business"; he seems nevertheless to be searching for a classification that will command the general agreement that Linnean classification gets. But satisfactory Linnean classification summarizes the course of evolution, and there is no reason to assume that viruses, except within closely related groups, have undergone a similar process.

N. W. PIRIE

TECHNOLOGY AND ECONOMICS AND THEIR RELATION TO PUBLIC POLICY*

By The Right Hon LORD ROBBINS, C.B., F.B A

Chairman of the Committee on Higher Education

In common with the Rector of the Imperial College of Science and Technology and nine other colleagues, I have already expressed my views on the subject of higher education and its future† I therefore offer here a few reflexions on technology and economics in relation to public policy I shall deal first with technology *per se*, then with its relations with economics, then their joint status in regard to public policy, and finally briefly with the use of skills and knowledge they involve in the conduct of public business

I do not need to spend time on the immense direct increase in our power to satisfy our various wants which is due to technical progress One has only to travel in some backward area where the major operations of agriculture and construction are still done by hand or beast to realize how much we owe to the machine in this respect It is more interesting, I suggest, to contemplate the subtler influence on social structure and social relations which are due to technical change We have all heard of the social changes which have followed the discovery of methods of production bringing together large masses of workpeople in towns and in big factory installations The influence on contemporary politics of the introduction of television is a matter of common observation But I wonder how many people have reflected on the immense change in the social position of women which is due to the internal combustion engine—an invention which has equalized the power of the sexes to control the lighter types of vehicle and thus freed the physically weaker from dependence in this respect on husbands or coachmen

Such influences are so continuous and so widespread that some have gone so far as to claim for them an almost exclusive status as ultimate historical explanation The history of tools is the history of mankind, it is said. But although this may be a very healthy corrective to the histories which tend to explain all change in terms of the influence of kings or priests or politicians, it certainly goes too far, in regard to both detail and broad outline Our tastes are not all conditioned by technical availabilities, it is a significant circumstance that the age of the electric razor should have witnessed a proliferation of beards The arts are not exclusively determined by present-day modes of production, in spite of certain museum labels of the Stalin era, the paintings of Cezanne are not "a characteristic product of the period of heavy industry" The broad structure of human society is certainly not only a by-product of mechanical convenience, the division of the Western World into independent sovereign States and all the ups and downs which are the consequences thereof are tragic examples of the fact that influences other than technology play their part in human destiny It is true that the growth of States was aided by the invention of gunpowder, and it may be that the invention of the hydrogen bomb will eventually induce their consolidation, but if this happens—and the outcome is by no means certain—a great deal will have occurred in between which, in any sane view, cannot be interpreted in terms of technological influences

But whether or not technology has determined the course of history in the past, it is sometimes said that it ought to determine it in the future I do not think the technologists have often made this claim they are usually much better balanced personalities than those who romanticize them But the idea of a world planned and run by technologists has swum before the eyes of many social visionaries, from St. Simon onwards One of the most forceful expressions of this occurs in Thorstein Veblen's *The Engineers and the Price System*, where, speaking of the modern industrial system, he asserts "It is a mechanically organized structure of technical processes designed, installed and conducted by production engineers Without them and their constant attention the industrial equipment, the mechanical appliances of industry, will foot up to just so much junk The material welfare of the community is unreservedly bound up with the due working of this industrial system and therefore with its unreserved control by the engineers, *who alone are competent to manage it*" [my italics]

I am quite sure that this is a mistake As I shall be arguing later, I am very much in favour of the increased employment of technologists in high places But it will not be their knowledge as technologists which will determine the ultimate decisions For the ultimate decisions involve problems which technology as such is quite unable to solve

Consider for a moment a very simple example—the problem of housing construction Let us assume for purposes of discussion that the supply of houses is on a public basis so that there are no complications arising from the relation between the State and private enterprise, and let us assume further that the amount of house-room to be provided has already been decided There remains, therefore, the question what techniques to adopt, and at first sight this might appear to be entirely technological But this is not so The techniques of house construction run through an almost infinite range of possibilities, from those which provide mud huts to those which provide buildings of almost limitless durability, from the provision of bare utility to the last sophistications of opulence Now, clearly, if no other considerations were involved, we should opt for maximum durability and maximum amenity, and, æsthetics apart, the information we needed would be technological But actually we are at once confronted with the hard fact that the different kinds of labour and materials involved are also involved in hundreds of alternative forms of production, in factory construction, in shipbuilding, in the production of tractors and weapons, to say nothing of road building and agriculture, and that, in conditions of reasonably full employment, there are not enough to satisfy all these demands to the point of satiety Hence, if the general production plan is to be rational, account must be taken of such other uses Just to give complete priority to the production of housing units of the maximum durability and convenience would not be sensible The choice of techniques in any one branch of production must therefore depend on the general availability of resources and their allocation between different alternatives Now there is no purely technological calculus which can solve the allocation problem There is no technological principle which by itself can tell us how much steel or how much labour to allot to this branch of industry and that

It is here that economics has a contribution to make —although, as I shall be arguing later on, it is only a contribution, not a final solution For it is one of the specific tasks of the economists to study the distribution of resources which are in limited supply; and it is his business, given appropriate information regarding the possible range of techniques on one hand, and the conditions of demand for possible products on the other, to devise criteria of appropriate allocation. Given information of this sort, he ought to be able to show what proportions of existing resources should be allocated to house building and consequently which of the various techniques available it would be most suitable to adopt I would not wish to be thought to be saying that he can do this, for a host of difficulties is concealed in the assumption that the relevant information is available But such at least is the kind of problem and the kind of solution with which his prescriptions are concerned

---

* Substance of the address delivered by Lord Robbins as Special Visitor to the Imperial College of Science and Technology, University of London, at the annual Commemoration Day ceremony in the Royal Albert Hall on October 24 (see also p 632 of this issue)

Now the last thing I should want to do would be to suggest that all that scientists and technologists do is to supply parameters for our equations On a long view of history, who can question that technologists have done far more for humanity than anything which economists have been able to do up to date? If the technologists like this way of putting things better, they can simply say that the other factors which the economic calculus has to take into account are simply so many necessary constraints on their perfection I certainly would not quarrel with that at all, it would be just another way of bringing out the point that I am trying to make that the two kinds of consideration, though related, are not identical and that technical optima are not necessarily economic optima. For the technical optimum in any line of production is achieved when, given the existing state of knowledge, the construction is as efficient as can be conceived, regardless of cost But the economic optimum is essentially related to cost—what you go without when you do one thing rather than another, it involves a balance of alternatives not technically related Hence, technical and economic optima can only coincide in a world in which there are no costs—that is to say, in a world in which the economic problem has ceased to exist This, to put it mildly, is some way ahead

But economics too has its limits As we have seen, if it is told what people want and in what quantities at different prices, it can combine this information with the information it gets from the various technologists, so as to depict the most economical use of the available resources But it does not tell us why people want things, or whether they ought to do so Think for a moment of the problem of steel allocation Some of the steel will be wanted for goods which eventually find their way to the market, and if we are content with the results in that sector of the economy of allowing people to spend their money according to their fancy, then market demands can be taken as ultimate data But some steel will doubtless be wanted for the production of weapons and warlike stores and some for the construction of schools and hospitals, and in such cases there is no market in the final sense, and the decision what to produce and how much is essentially one which is a matter of political judgment

In the case of defence, this is obvious But it is no less true with education and health Attempts may be made to measure the commercial return on teaching and hospital treatment and, in their way, they have their uses But, if taken too seriously, they tend to ignore social consequences which are not at all susceptible of such measurement, yet which in the long run are even more important Even in the market sector, the decision to leave things to the play of individual and group demand is also in essence political It involves both an implicit acceptance of the existing distribution of power to spend and an acceptance of the view that in this sphere the individuals concerned are the best judges of what is good for them I do not say that this is wrong On the whole, where private goods are concerned, I personally prefer markets to regulation and where the distribution of wealth is held to be unsuitable, I prefer taxes and subsidies to rationing All that I am trying to drive home is that, even here, economics is open-ended and by itself furnishes no final guide to policy Equally with technology, although on a different plane, it is instrumental rather than ultimate

If this is true, it follows that there are no easy solutions. Neither technology nor economics can provide the answers to the ultimate questions Where are we going ? What do we want to do ? In so far as these can be answered in general terms, we must still depend on moral and political philosophy and on the vision of inspired thinkers In so far as day-to-day business is concerned, we are still at the mercy of what Adam Smith described as that "insidious and crafty animal, vulgarly called a statesman or politician, whose counsels are directed by the momentary fluctuations of affairs" They may be a somewhat disillusioning conclusion, yet it is difficult to see how it can be avoided In the last analysis decisions regarding human destiny rest on volitions and valuations which do not lie within the compass of either of our respective techniques

But at this point it is important that I should avoid misapprehension on the part of readers The fact that neither technology nor economics in themselves can afford ultimate guidance concerning social choice and social action does not in the least mean that in coming to decisions of this sort the information they do provide can be sensibly neglected The political philosopher who speculates on what shapes and contents of the desirable society is likely to waste a good deal of time unless he takes account of what shapes and contents of societies are *possible*—as we can see from the intellectual wreckage of many philosophical Utopias and the pure futility of much of the exhortation which we have to endure from such quarters Moreover, the insidious and crafty animal seeking to control "the momentary fluctuations of affairs" is also likely to land himself in all sorts of difficulties if he does not pay at least some heed to the technological and economic limitations of alternative stratagems

Indeed, in a complex society such as ours, resting on advanced technology and involving the most intricate and far-reaching economic relationships, the statesman who would seek to make fundamental decisions without some knowledge and advice of this sort is about as likely to succeed as a would-be artist who would take it on himself to carry out some vast decoration without a knowledge of the properties of pigments or the elements of perspective and drawing. He may succeed as some artists so deficient have succeeded But the success is inevitably in the nature of a fluke and carries with it no guarantee of continuity Or, if I may vary my simile, he is like a would-be pilot of a modern aircraft who attempts to fly without knowledge of the capacity of his craft or appropriate navigational aids It is true that neither aeronautical engineering nor navigational instruments will solve the ultimate questions where he wants to go But, given his ultimate goal, he will be lucky indeed if he gets there without instrumental knowledge

It is, therefore, a matter of considerable concern to all of us to see that the conduct of those who rule over us is sufficiently informed by technological and economic knowledge As I see things, there is a two-fold problem here There is the problem of ensuring that there is available in the machinery of Government a sufficiency of expert knowledge of this sort, and there is the further problem of seeing that the conduct of Government as such is sufficiently informed by an awareness of the importance of such knowledge and its relevance to ultimate decisions so that it is called into operation in the appropriate context

At the present day the first of these problems does not seem any longer to present insurmountable difficulties Doubtless, there are all sorts of questions of detail which still await solution, and I should be the last to say that our provision in this respect is adequate—it is still deficient in both fields But the need for technological and economic advice as such seems to me to be fairly generally acknowledged, and we must not complain too much of a certain time-lag in meeting it, though we should all do our best in our respective ways to help to abbreviate it We must be careful, too, in making public criticisms, that we get our facts right. It is a sad comment on the quality of public discussion of these matters that, at a time when various publicists are denouncing the poverty in this respect of the public service in general and the Treasury in particular, more than half the top administrators in the Treasury have degrees or similar qualifications as economists

It is the second problem which worries me more the problem how to bring it about that the general conduct of public affairs and the state of mind of those who rule over us is sufficiently informed of the relevance of technology and economics and the powerful assistance they can give I think this problem is very important If the quality of actual discussion in this respect is compared to what it might be, it is all too painfully obvious what a long way there is to go But I do not see any simple answer As I have tried to show earlier, I do not think we shall get anywhere by pitching our claims too high—by contending that either technology or economics holds the key to human destiny For that would be false, and to rely on that kind of argument would simply provide yet another pretext to the Philistines for not taking us at our true worth In the long run I should hope much from the presence in *non-specialized* jobs in the public service and business of more persons with a technological or economic educational background; the moral value of that sort of training with its objectivity and its humility *vis-à-vis* the ultimate problems of the universe is still often insufficiently appreciated I think also that much can be done by patient participation by technologists and economists in the public discussion of questions to which their expert knowledge is germane The business of politics is much too serious nowadays to be left to the politicians I hope too that, as time goes on, teaching in schools and universities will come to convey even to those who do not aspire to be experts in these fields some idea of their general relevance and the part they can play in human progress

But this brings me to the threshold of a subject which at the outset I declared it my intention to avoid I will conclude, therefore, by expressing my conviction that, in the creation of this broader understanding and this more enlightened outlook, the Imperial College of Science and Technology has a notable part to play, and my firm confidence that it will not fail to rise to the opportunity

INTERGROUP SELECTION IN THE EVOLUTION OF SOCIAL SYSTEMS

By Prof V. C. WYNNE-EDWARDS
Department of Natural History, University of Aberdeen

IN a recent book[1] I advanced a general proposition which may be summarized in the following way (1) Animals, especially in the higher phyla, are variously adapted to control their own population densities (2) The mechanisms involved work homeostatically, adjusting the population density in relation to fluctuating levels of resources; where the limiting resource is food, as it most frequently is, the homeostatic system prevents the population from increasing to densities that would cause over-exploitation and the depletion of future yields. (3) The mechanisms depend in part on the substitution of conventional prizes, namely, the possession of territories, homes, living space and similar real property, or of social status as the proximate objects of competition among the members of the group concerned, in place of the actual food itself (4) Any group of individuals engaged together in such conventional competition automatically constitutes a society, all social behaviour having sprung originally from this source

In developing the theme it soon became apparent that the greatest benefits of sociality arise from its capacity to override the advantage of the individual members in the interests of the survival of the group as a whole The kind of adaptations which make this possible, as explained more fully here, belong to and characterize social groups as entities, rather than their members individually This in turn seems to entail that natural selection has occurred between social groups as evolutionary units in their own right, favouring the more efficient variants among social systems wherever they have appeared, and furthering their progressive development and adaptation

The general concept of intergroup selection is not new It has been widely accepted in the field of evolutionary genetics, largely as a result of the classical analysis of Sewall Wright[2-4]. He has expressed the view that "selection between the genetic systems of local populations of a species . . has been perhaps the greatest creative factor of all in making possible selection of genetic systems as wholes in place of mere selection according to the net effects of alleles"[4] Intergroup selection has been invoked also to explain the special case of colonial evolution in the social insects[5-7]

In the context of the social group a difficulty appears, with selection acting simultaneously at the two levels of the group and the individual It is that the homeostatic control of population density frequently demands sacrifices of the individual, and while population control is essential to the long-term survival of the group, the sacrifices impair fertility and survivorship in the individual. One may legitimately ask how two kinds of selection can act simultaneously when on fundamental issues they are working at cross purposes At first sight there seems to be no easy way of reconciling this clash of interests, and to some people consequently the whole idea of intergroup selection is unacceptable

Before attempting to resolve the problem it is necessary to fill in some of the background and give it clearer definition. The survival of a local group or population naturally depends among other things on the continuing annual yield of its food resources. Typically, where the tissues of animals or plants are consumed as food, persistent excessive pressure of exploitation can rather quickly overtax the resource and reduce its productivity, with the result that yields are diminished in subsequent years This effect can be seen in the overfishing of commercial fisheries which is occurring now in different parts of the world, and in the overgrazing of pastoral land, which in dry climates can eventually turn good grassland into desert Damage to the crop precedes the onset and spread of starvation in the exploiting population, and may be further aggravated by it The general net effect of over-population is thus to diminish the carrying-capacity of the habitat

In natural environments undisturbed by man this kind of degradation is rare and exceptional the normal evolutionary trend is in the other direction, towards building up and sustaining the productivity of the habitat at the highest attainable level Predatory animals do not in these conditions chronically depress their stocks of prey, nor do herbivores impair the regeneration of their food-plants Many animals, especially among the larger vertebrates (including man), have themselves virtually no predators or parasites automatically capable of disposing of a population surplus if it arises

It is the absence or undependability of external destructive agencies that makes it valuable, if not in some cases mandatory, that animals should be adapted to regulate their own numbers By so doing, the population density can be balanced around the optimum level, at which the highest sustainable use is made of food resources

Only an extraordinary circumstance could have concealed this elementary conclusion and prevented our taking it immediately for granted Some eight or more thousand years ago, as neolithic man began to achieve new and greatly enhanced levels of production from the land through the agricultural revolution, the homeostatic conventions of his hunting ancestors, developed there as in other primates to keep population density in balance with carrying-capacity, were slowly and imperceptibly allowed to decay We can tell this from the centrally important place always occupied by fertility-limiting and functionally similar conventions in the numerous stone-age cultures which persisted into modern times[8] Since these conventions disappeared nothing has been acquired in their place growing skills in resource development have, except momentarily, always outstripped the demands of a progressively increasing population, there has consequently been no effective natural selection against a freely expanding economy. So far as the regulation of numbers is concerned, the human race provides a spectacular exception to the general rule

A secondary factor, tending to obscure the almost universal powers possessed by animals for controlling their numbers, is our everyday familiarity with insect and other pests which appear to undergo uncontrolled and sometimes violent fluctuations in abundance In fact, human land-use practices seldom leave natural processes alone for any length of time vegetation is gathered, the ground is tilled, treated or irrigated, single-species crops are planted and rotated, predators and competitors are destroyed, and the animals' regulating mechanisms are thereby, understandably, often defeated In the comparably drastic environmental fluctuations of the polar and desert regions, similar population fluctuations occur without human intervention

The methods by which natural animal populations curb their own increase and promote the efficient exploitation of food resources include the control of recruitment and, when necessary, the expulsion and elimination of unwanted surpluses The individual member has to be governed by the homeostatic system even when, as commonly happens, this means his exclusion from food in the midst of apparent plenty, or detention from reproduction when others are breeding The recruitment rate must be determined by the contemporary relation between population density and resources, under average conditions, therefore, only part of the potential fecundity of the group needs to be realized in a given year or generation

This is a conclusion amply supported by the results of experiments on fecundity versus density in laboratory populations, in a wide variety of animals including Crustacea, insects, fish and mammals, and also by field data from natural populations[1]. But it conflicts with the assumption, still rather widely made, that under natural selection there can be no alternative to promoting the fecundity of the individual, provided this results in his leaving a larger contribution of surviving progeny to posterity[9] This assumption is the chief obstacle to accepting the principle of intergroup selection

One of the most important premises of intergroup selection is that animal populations are typically self-perpetuating, tending to be strongly localized and persistent on the same ground This is illustrated by the widespread use of traditional breeding sites by birds, fishes and animals of many other kinds, and by the subsequent return of the great majority of experimentally marked young to breed in their native neighbourhood It is true of non-migratory species, for example the more primitive communities of man, and all the long-distance two-way migrants that have so far been experimentally tagged, whether they are birds, bats, seals or salmon, have developed parallel and equally remarkable navigating powers that enable them to return precisely to the same point, and consequently preserve the integrity of their particular local stock Isolation is normally not quite complete, however Provision is made for an element of pioneering, and infiltration into other areas; but the gene-flow that results is not commonly fast enough to prevent the population from accumulating heritable characteristics of its own. Partly genetic and partly traditional, these differentiate it from other similar groups

Local groups are the smallest racial units capable of continuous existence for long enough to undergo evolutionary differentiation In the course of generations some die out, others survive, and have the opportunity to spread into new or vacated ground as it becomes available, themselves subdividing as they grow In so far as the successful ones take over the habitat left vacant by the unsuccessful, the groups are in a relation of passive competition Their survival or extinction is partly a matter of chance, arising from various forms of *force majeure*, including secular changes in the environment, for the rest it is determined, in general terms, by heritable qualities of fitness

Gene-frequencies within the group may alter as time passes, through gene-flow, drift (the Sewall Wright effect), and selection at the individual level Through the latter, adaptations to local conditions may accumulate Population fitness, however, depends on something over and above the heritable basis that determines the success as individuals of a continuing stream of independent members It becomes particularly clear in relation to population homeostasis that social groups have highly important adaptive characteristics in their own right

When the balance of a self-regulating population is disturbed, for example by heavy accidental mortality, or by a change in food-resource yields, a restorative reaction is set in motion If the density has dropped below the optimum, the recruitment rate may be increased in a variety of ways, most simply by drawing on the reserve of potential fecundity referred to earlier, and so raising the reproductive output Immigrants appearing from surrounding areas can be allowed to remain as recruits also If the density has risen too high, aggression between individuals may build up to the point of expelling the surplus as emigrants, the reproductive rate may drop, and mortality due to social stress (and in some species cannibalism) may rise These are typical examples of density-dependent homeostatic responses

Seven years of investigation of the population ecology of the red grouse (*Lagopus scoticus*) near Aberdeen, by the Nature Conservancy Unit of Grouse and Moorland Ecology, have revealed many of these processes at work[10] Their operation in this case depends to a great extent on the fact that individual members of a grouse population living together on a moor, even of the same sex, are not equal in social status Some of the cock birds are sufficiently dominant to establish themselves as territory owners, parcelling out the ground among them and holding sway over it, with a varying intensity of possessiveness, almost the whole year round During February–June their mates enjoy the same established status

In the early dawn of August and September mornings, after a short and almost complete recess, the shape of a new territorial pattern begins to be hammered out In most years this quickly identifies a large surplus of males, old and young, which are not successful in securing any part of the ground and consequently assume a socially inferior status They are grouped with the hens at this stage as unestablished birds, and day by day their security is so disturbed by the dawn aggressive stress that almost at once some begin to get forced out, never to return By about 8 a m each day the passion subsides in all but the most refractory territorial cocks, after which the moor reverts to communal ground on which the whole population can feed freely for the rest of the day. As autumn wears on and turns to winter, the daily period of aggression becomes fiercer and lasts longer; birds with no property rights have to feed at least part of the time on territorial ground defended by owners that may at any moment chase them off. More and more are driven out altogether; and since they can rarely find a safe nook to occupy elsewhere in the neighbourhood, they become outcasts, and are easily picked up by hawks and foxes, or succumb to malnutrition. Females are included among those expelled, but about February the remaining ones begin to establish marital attachments, and at the same time, quite suddenly, territories are vigorously defended all day. Of the unestablished birds still present in late winter, some achieve promotion by filling the gaps caused by casualties in the establishment. Some may persist occasionally until spring, but unless a cock holds a territory exceeding a minimum threshold capacity, or a hen becomes accepted by a territorially qualified mate, breeding is inhibited.

Territories are not all of uniform size, and on average the largest are held by the most dominating cocks. More important still, the average territory size changes from year to year, thus varying the basic population density, apparently in direct response to changes in productivity of the staple food-plant, heather (*Calluna vulgaris*). As yet this productivity has been estimated only by subjective methods, but significant mutual correlations have been established between annual average values for body-weight of adults, adult survival, clutch-size, hatching success, survival of young, and, finally, breeding density the following year. As would be expected with changing densities, the size of the autumn surplus, measured by the proportions of unestablished to established birds, also varies from year to year.

There are increasing grounds for concluding that this is quite a typical organization, so far as birds are concerned, and that social stratification into established and unestablished members, particularly in the breeding season, is common to many other species, and other classes of animals. In different circumstances the social hierarchy may take the form of a more or less linear series or peck-order. Hierarchies commonly play a leading part in regulating animal populations, not only can they be made to cut off any required proportion of the population from breeding, but also they have exactly the same effect in respect of food when it is in short supply. According to circumstances, the surplus tail of the hierarchy may either be disposed of or retained as a non-participating reserve if resources permit.

It is not necessary here to explore in detail the elaborate patterns of behaviour by which the social hierarchy takes effect. The processes are infinitely varied and complex, though the results are simple and functionally always the same. The hierarchy is essentially an overflow mechanism, continuously variable in terms of population pressure on one hand, and habitat capacity on the other. In operation it is purely conventional, prescribing a code of behaviour. When a more dominant individual exerts sufficient aggressive pressure, usually expressed as threat although frequently in some more subtle and sophisticated form, his subordinates yield, characteristically without physical resistance or even demur. It may cost them their sole chance of reproduction to do so, if not their lives. The survival of the group depends on their compliance.

This has been taken as an example to illustrate one type of adaptation possessed by the group, transcending the individuality of its members. It subordinates the advantage of particular members to the advantage of the group, its survival value to the latter is clearly very great. The hierarchy as a system of behaviour has innumerable variants in different species and different phyla, analogous to those of a somatic unit like the nervous or vascular system. Like them, it must have been subject to adaptive evolutionary change through natural selection, yet it is essentially an 'organ' of a social group, and has no existence if the members are segregated.

A simple analogy may possibly help to bring out the significance of this point. A football team is made up of players individually selected for such qualities as skill, quickness and stamina, material to their success as members of the team. The survival of the team to win the championship, however, is determined by entirely distinct criteria, namely, the tactics and ability it displays in competition with other teams, under a particular code of conventions laid down for the game. There is no difficulty in distinguishing two levels of selection here, although the analogy is otherwise very imperfect.

The hierarchy is not the only characteristic of this kind. There are genetic mechanisms, such as those that govern the optimum balance between recombination and linkage, in which the benefit is equally clearly with the group rather than the individual. Without leaving the sphere of population regulation, however, we can find a wide range of vital parameters, the optima of which must similarly be determined by intergroup selection. Among those discussed at length in the book already cited[1] are (1) the potential life-span of individuals and, coupled with it, the generation turnover rate, (2) the relative proportions of life spent in juvenile or non-sexual condition (including diapause) and in reproduction, (3) monotely (breeding only for a single season) versus polytely, (4) the basal fecundity-level, including, in any one season, the question of one brood versus more than one.

These and similar parameters, differing from one species or class to another are interconnected. Their combined effects are being summed over the whole population at any one time, and over many generations in any given area. It is the scale of the operation in time and space that precludes an immediate experimental test of group selection. An inference that may justifiably be drawn, however, is that maladjustment sufficient to interfere persistently with the homeostatic mechanism must either cause a progressive decline in the population or, alternatively, a chronic over-exploitation and depletion of food resources: in the end either will depopulate the locality.

There still remains the central question as to how an immediate advantage to the individual can be suppressed or overridden when it conflicts with the interests of the group. What would be the effect of selection, for example, on individuals the abnormal and socially undesirable fertility of which enabled them and their hereditary successors to contribute an ever-increasing share to future generations?

Initially, groups containing individuals like this that reproduced too fast, so that the overall recruitment rate persistently tended to exceed the death-rate, must have repeatedly exterminated themselves in the manner just indicated, by overtaxing and progressively destroying their food resources. The earliest adaptations capable of protecting the group against such recurrent disasters must necessarily have been very ancient; they may even have been acquired only once in the whole of animal phylogeny, and in this respect be comparable with such basic morphological elements as the mesoderm, or, perhaps, the cœlom. Once acquired, the protective adaptations could be endlessly varied and elaborated. It is inherently difficult to reconstruct the origin of systems of this kind, but genetic mechanisms exist which could give individual breeding success a low heritability, or, in other words, make it resistant to selection. This could be relatively simply achieved, for example, if the greatest success normally attached to heterozygotes for the alleles concerned, creating the stable situation characteristic of genetic homeostasis[11].

A more complex system can be discerned, as it has developed in many of the higher vertebrates where the breeding success of individuals is very closely connected with social status. This connexion must necessarily divert an enormous additional force of selection into promoting social dominance, and penalizing the less fortunate subordinates in the population that are prevented from breeding or feeding, or get squeezed out of the habitat. Yet it is self-evident that the conventional codes under which social competition is conducted are in practice not jeopardized from this cause selection pressure, however great, does not succeed in promoting a general recourse to deadly combat or treachery between rivals, nor does it, in the course of generations, extinguish the patient compliance of subordinates with their lot

The reason appears to be that social status depends on a summation of diverse traits, including virtually all the hereditary and environmental factors that predicate health, vigour and survivorship in the individual. While this is favourable to the maintenance of a high-grade breeding stock, and can result in the enhancement through selection of the weapons and conventional adornments by which social dominance is secured, dominance itself is again characterized by a low heritability, as experiments have shown In many birds and mammals, moreover, individual status, quite apart from its genetic basis, advances progressively with the individual's age Not only are the factors that determine social and breeding success numerous and involved, therefore, but the ingredients can vary from one successful individual to the next A substantial part of the gene pool of the population is likely to be involved and selection for social dominance or fertility at the individual level correspondingly dissipated and ineffective, except in eliminating the sub-standard fringe

Such methods as these which protect group adaptations, including both population parameters and social structures, from short-term changes, seem capable of preventing the rise of any hereditary tendency towards anti-social self-interest among the members of a social group Compliance with the social code can be made obligatory and automatic, and it probably is so in almost all animals that possess social homeostatic systems at all In at least some of the mammals, on the contrary, the individual has been released from this rigid compulsion, probably because a certain amount of intelligent individual enterprise has proved advantageous to the group In man, as we know, compliance with the social code is by no means automatic, and is reinforced by conscience and the law, both of them relatively flexible adaptations.

There appears therefore to be no great difficulty in resolving the initial problem as to how intergroup selection can override the concurrent process of selection for individual advantage. Relatively simple genetic mechanisms can be evolved whereby the door is shut to one form of selection and open to the other, securing without conflict the maximum advantage from each, and since neighbouring populations differ, not only in genetic systems but in population parameters (for example, mean fecundity[12]) and in social practices (for example, local differences in migratory behaviour in birds, or in tribal conventions among primitive men), there is no lack of variation on which intergroup selection can work.

GEOMAGNETIC PARAMETERS AND PSYCHIATRIC HOSPITAL ADMISSIONS

By PROF HOWARD FRIEDMAN and PROF ROBERT O. BECKER

Syracuse Veterans Administration Hospital, New York, and State University of New York Upstate Medical Center

AND

PROF. CHARLES H. BACHMAN

Syracuse University, New York

ALTHOUGH the relationship of natural environmental physical forces to human behaviour has always been a matter of general interest and speculation, there has been a paucity of systematic investigations in this connexion among modern scientific workers Buettner[1], in a critique of the literature bearing on correlations between bioclimatological parameters and human health and behaviour, pointed to the general confusion in the field as well as to the very limited unequivocal findings consisting of the establishment of two 'potentially harmful' weather types The literature in the field of geomagnetic parameters and human behaviour is more restricted in quantity and in significance of findings

Possibly the most ambitious pertinent investigation is that of Dull and Dull[2] In an analysis of approximately 40,000 cases over a period of 60 months they demonstrated graphically a clearly observable relationship between the 67 magnetic storms occurring during this time, and the incidence of nervous and mental diseases and suicides Their results, however, were not subjected to statistical treatment Berg[3], reviewing the literature pertaining to the relationships between environmental geophysical parameters and the human population, concluded that firm evidence for or against such relationships is still lacking

The relative indifference of the behavioural scientists to this problem may possibly be due to the lack of that type of theoretical framework which could permit the interrelationship of the two parameters to be derived as a logical consequence There has been, however, a growing appreciation of, and body of empirical findings related to, one circumscribed aspect of the overall area, the biological effects of magnetic fields[4–6], particularly with reference to infra-human organisms A parallel related concern has been the investigations into the electrical organizations of the living organism Thus, in a review of recent work in the relationship between direct current electricity and living organisms[7], it was suggested that the direct-current electrical system of the organism could be conceived as a control system which could be influenced by external force fields These considerations led to a pilot investigation[8] which examined the relationship between gross manifestations of extreme human psychological disturbance and natural magnetic field intensity The psychiatric admissions to two Syracuse, New York, hospitals were correlated with K-index[9] sums as measured at the Fredericksburg Magnetic Observatory, Virginia, for approximately a four-year period The statistically significant correlation ratios obtained for non-linear relationships, η, of 0 26 and 0 27 suggested that at least some relationship exists between the incidence of psychiatric disturbance and some geophysical parameter associated with the magnetic field

The investigation reported here is an extension of the pilot work utilizing a larger sample of psychiatric hospital admissions and, as advised by Bartels[10], a linear measure of the magnetic field intensity, ak, the equivalent 3-h range, rather than the quasi-logarithmic scale of K-indices In addition, ap, the planetary counterpart to ak was used

Daily admissions to seven central New York State psychiatric hospitals and to the Psychiatric Service of a Veterans Administration General Medical and Surgical Hospital during July 1, 1957–October 31, 1961, were obtained Transfers from other psychiatric institutions were excluded Total admissions included in the data are 28,642

For the same period of time K-indices, as determined at the Fredericksburg Magnetic Observatory, were obtained from the Coast and Geodetic Survey, U S Department of Commerce The K-index, as described by Bartels[10], reflects the amplitude, a, of the most disturbed component of the magnetic field, measured every 3 h The values of a are customarily condensed, for convenience of reporting, into a quasi-logarithmic scale for K, ranging from 0 to 9 In this work each 3-h K-index was reconverted into the equivalent 3-h range, ak, by means of a table of Bartels[10], thus providing a linear measure The eight daily values of ak were then summed to arrive at a daily ak sum

The planetary 3-h K-indices, Kp, as furnished by the U S Department of Commerce, Bureau of Standards, Central Radio Propagation Laboratory, Boulder, Colorado, were also reconverted into 3-h equivalent planetary amplitudes, ap, and then summed to obtain a daily ap sum

It was decided to examine 7-, 14-, 21-, 28- and 35-day time-periods to correlate with the corresponding periods of the geomagnetic parameters for the following reasons First, the time between onset of psychiatric disturbance necessitating hospitalization and actual admission varies with a host of uncontrollable factors, not the least of which are differing hospital admission procedures It is also impossible to specify *a priori* the most meaningful duration and extent of geomagnetic event Secondly, inspection of the hospital admission data readily revealed one artefact among the many possible contributors to the number of uncontrolled variables in the crude measure of this parameter Every Sunday was marked by a striking drop in admissions, undoubtedly reflecting differing admission policies and procedures The selection of the aforementioned time-periods thus provided a constant number of Sundays when all the possible 7-, 14-, 21-, 28- and 35-day intervals were examined

To obtain the 7-, 14-, 21-, 28- and 35-day values, the number of admissions for every possible consecutive 7-, 14-, 21-, 28- and 35-day period was summed and correlated with the geomagnetic parameter sums for the corresponding periods Thus 7-day periods yielded 7 correlations obtained from using days 1 through 7, 8 through 14, 15 through 21, etc , for the first correlation, then days 2–8, 9–15, 16–22, etc , for the second correlation, and continuing on in similar fashion to the seventh correlation which used days 7–13, 14–20, 21–27, etc This provided 3 correlations with 226 pairs of comparisons (N), and 4 with 225 pairs The other time-periods were treated similarly, thus giving 3 correlations with N's of 113 and 11 correlations with N's of 112 for the 14-day periods, 10 correlations with N's of 75 and 11 with N's of 74 for the 21-day periods 17 correlations with N's of 56 and 11 with N's of 55 for 28-day periods, and 10 correlations with N's of 45 and 25 with N's of 44 for the 35-day periods

In order to compare admissions to the greater intensities of geomagnetic disturbance, a listing of the principal magnetic storms from July 1, 1957, until October 31, 1961, identified by the Fredericksburg Magnetic Observatory, Virginia, was obtained from reports contained in the *Journal of Geophysical Research* and *International Geophysical Year Bulletins* The number of days of storm in the 7-, 14-, 21-, 28- and 35-day periods were then correlated with the hospital admissions for the corresponding time-periods

The product moment correlation coefficients, r, derived from the comparison of total geomagnetic activity parameters, as reflected in ak and ap, with hospital admissions are negligible in magnitude regardless of time-period used. Table 1 presents the correlation coefficients obtained from the comparison of the 7-, 14-, 21-, 28- and 35-day periods of hospital admissions with the number of days of magnetic storm for the corresponding periods of time The correlations between the number of days of magnetic storm and admissions for 7-day periods can be considered as negligible The 14 correlation coefficients obtained by using the 14-day periods range from +0 077 to +0 221, the latter figure being statistically significant ($P < 0\ 05$) The correlations of the 21-day periods range from +0 116 to +0 305 with 5 statistically significant ($P < 0\ 05$) coefficients The 28-day correlations range from +0 167 to +0 332, and 13 are statistically significant ($P < 0\ 05$) The 35-day correlation coefficients range from a low of +0 222 to an unexpected high of +0 345, and 11 are statistically significant ($P < 0\ 05$)

Table 1 CORRELATIONS BETWEEN DAYS OF MAGNETIC STORM AND PSYCHIATRIC HOSPITAL ADMISSIONS

Admission periods	No of r's	Range	Median r
7-day	$3(N = 226) + 4(N = 225)$	−0 010–+0 122	+0 043
14-day	$3(N = 113) + 11(N = 112)$	+0 077–+0 221	+0 117
21-day	$10(N = 75) + 11(N = 74)$	+0 116–+0 305	+0 182
28-day	$17(N = 56) + 11(N = 55)$	+0 167–+0 332	+0 261
35-day	$10(N = 45) + 25(N = 44)$	+0 222–+0 345	+0 279

The use of unscreened heterogeneous hospital admissions as a measure of alteration in human behaviour is admittedly crude The host of uncontrolled variables makes this at best a gross approximation to psychological disturbance in the human population at large If one becomes intrigued with ætiological considerations there are then the further problems of the unknown time-period between occurrence of geomagnetic event and its significant effect on the organism, and the specification of the duration and extent of meaningful geomagnetic events Since the purpose of this work was simply to investigate whether any relationship could be found to exist between geomagnetic parameters and human behaviour, it was hoped that some of the effects of the uncontrolled variables in the behavioural parameter could be crudely minimized by randomization within a large sample, and that the problem of unknown time for effect of geomagnetic event could be attenuated in part by the use of 7-, 14-, 21-, 28-, and 35-day time-periods The results indicate that statistically significant low to marked linear relationships exist between geomagnetic parameters and a gross measure of human disturbance These relationships are evident when the measure of the geomagnetic parameter is restricted to those periods of higher disturbance which can be categorized as magnetic storms The total range of of geomagnetic activity, as reflected in planetary (ap) and more local (ak) natural magnetic field intensity parameters, does not reveal any significant relationship with psychiatric hospital admissions

The use of the five time-periods provides no definitive information about the optimal time between geomagnetic event and onset of psychological disturbance or time to achieve hospital admission However, inasmuch as the magnitude of the maximum correlation tends to increase with the size of the time-period used it suggests in part, that the optimal time may be closer to thirty-five days than seven days In part, it probably also reflects the attenuation of transient artefacts inherent in the hospital admission data

Although correlational investigations shed but little light on causal relationships, they nevertheless do provide a fertile field which can yield more significant testable hypotheses In view of the diversity of the two variables under investigation and the grossness of the measures, the present investigation offers correlations of a surprising magnitude In general, the tentative conclusion of the pilot study can be reaffirmed a significant relationship has been shown between psychiatric disturbance as reflected in hospital admissions and natural magnetic field intensity In any interpretation of this relationship it should be cautioned that it is beyond the scope of this investigation to determine whether the more meaningful geophysical parameter is magnetic field intensity *per se*, or some other geophysical parameter intimately associated with it Speculatively, the results are in keeping with the conception of the behaviour of an organism being significantly influenced, through the direct-current control system, by external force fields Attention is thus invited to a hitherto neglected dimension in the complexity of psychopathology specifically, and perhaps generally in all human behaviour

SATELLITE GRAVITY MEASUREMENTS AND CONVECTION IN THE MANTLE

By Prof S K. RUNCORN

Physics Department, University of Newcastle upon Tyne, and Jet Propulsion Laboratory, California Institute of Technology

THE discovery of non-axial and odd axial harmonic terms in the Earth's gravitational field from surface gravity observations[1] and, more recently, from the orbits of satellites[2], has been widely interpreted as showing that the Earth's mantle possesses a finite strength and that in consequence the occurrence of convection currents in the mantle is excluded The argument is that if the mantle acts as a fluid over periods of millions of years and convection currents are occurring in it, the continents should lie over the descending currents Munk and MacDonald[3] compared the coefficients of the spherical harmonics which represent the distribution of the oceans and continents with those of the gravity observations and found that no correlation exists, so that a strong argument against convection seemed to have been found (Jeffreys[1] had shown, on any reasonable isostatic hypothesis, that the gravitational attraction of the continental masses would be annulled by the deficiencies of mass supporting them below to about a milligal)

Because of their wave-lengths, the sources of the low harmonic gravity anomalies are reasonably located in the deeper parts of the mantle[4] These gravity anomalies

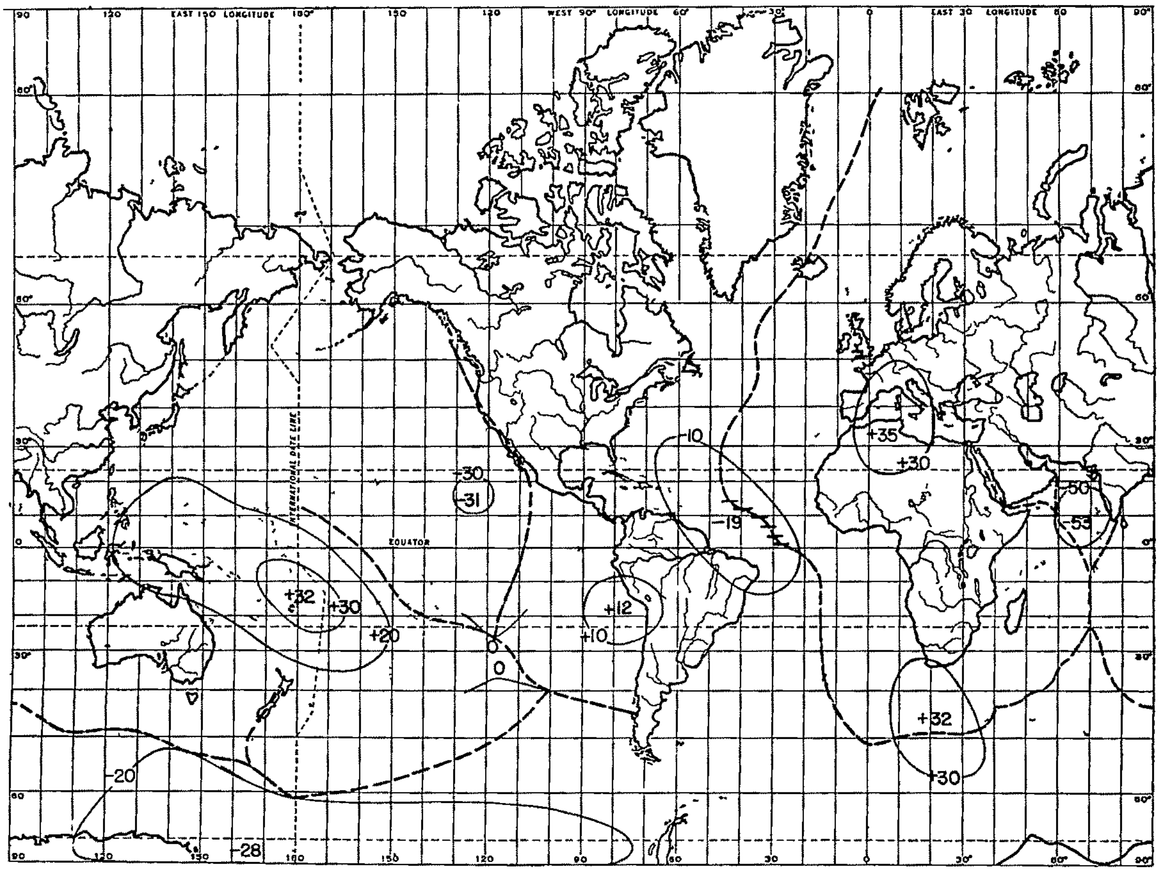

Fig 1 Dotted lines are the ocean rises[9], thin lines are contours of geoid surface[10] (in metres) (numbers given in centres of contour show positions and values of gravity highs and lows)

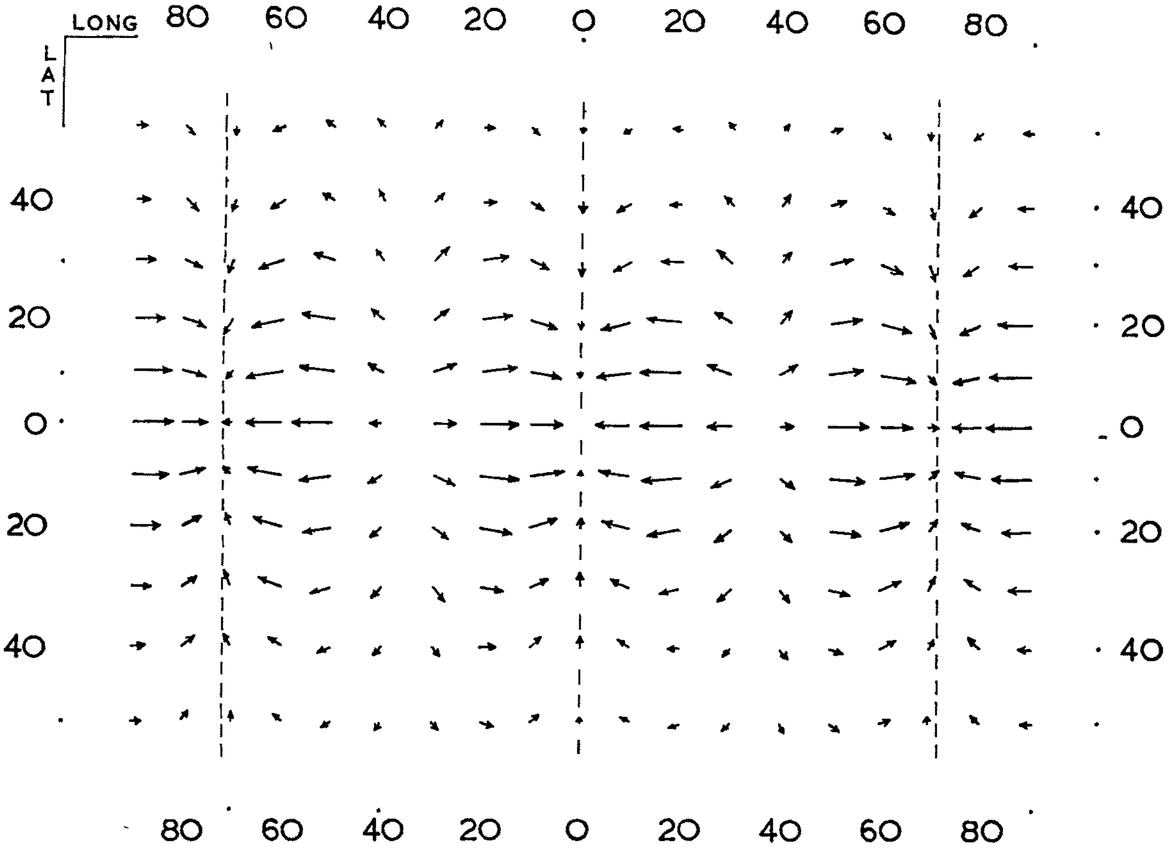

Fig 2. Horizontal flow distribution for a fifth degree sectorial harmonic convection current. Horizontal velocity components are proportional to lengths of arrows

must arise from deep-seated inequalities of density in the mantle, which, if flow were to be ruled out because of the finite strength of the mantle, result from events in the remote past of the Earth. For example, it has been recently suggested[5] that they are the scars left in the Earth by the breaking away of the Moon. This line of reasoning depends on a belief that the interior of the Earth can retain strains over 10^9 years. Until I recently suggested an alternative explanation[6], there seemed to be incontrovertible support for this view from the case of the Moon, the differences in the moments of inertia of which are thirty times those to be expected if the Moon were in hydrostatic equilibrium. This non-hydrostatic bulge towards the Earth of about 2 km is interpreted by Jeffreys[1] as a fossil tidal bulge, left from the period (10^9 years ago) when the Moon was much closer to the Earth. The internal stress difference required to support this bulge is 20 bars. It does not seem to have been recognized by the proponents of these views that their explanation of these departures from hydrostatic equilibrium in the interiors of the Moon and Earth (that the mantles have finite strength over 10^9 years) invokes remarkable mechanical properties. To cause the bulge on the Moon to subside completely, a strain of 10^{-3} would be required. If this has not occurred in 3×10^9 years, it means that the creep rate must have been less than 10^{-20} sec^{-1}. Thus what is demanded of the Earth and Moon are creep rates of less than 10^{-20} sec^{-1} under stresses of about 5 per cent of the breaking stress of rocks at ordinary temperatures. It is remarkable that our geophysical colleagues have not made widely known to engineers their technological breakthrough in discovering a material which, at elevated temperatures, has a creep rate only one millionth millionth of those encountered in the laboratory.

The explanation of the low degree harmonics of the Earth's gravitational field and the bulge on the Moon may more plausibly be sought in thermal convection[7,8]. An order of magnitude argument establishes the reasonableness of this solution for the Earth. I[7] showed that if a value for the viscosity of the mantle is taken of 10^{21} poise, and the velocities of the convection currents are inferred from the rates of displacement of the continents the temperature differences between the rising and falling streams on the equipotential surfaces are of the order of 1/3° C. Taking a volume coefficient of expansion for the mantle of 3×10^{-5} per °C, the deficiency of mass per unit surface in the uprising volume compared with the downgoing one is about 5×10^3 g/cm^2. This gives a gravity anomaly of the order of 10^{-2} cm/sec^2, or 30 m in geoid height, which are the values given by Jeffreys and those who have reduced the satellite gravity observations (see Fig 1).

But, as already explained here, Munk and MacDonald's negative correlation of the topography of the Earth with the satellite gravity anomalies has been a stumbling block. Further, although convection has been used to explain the ocean ridges, the convection currents being supposed to rise under the ridges, it has not been clear what relationship the satellite gravity observations have to these essentially linear features. It is the purpose of this communication to point this out.

Convection currents in a sphere or spherical shell may best be described using spherical harmonic functions $S_n(\theta,\varphi)$ when θ is co-latitude and φ is the longitude. The northward and eastward horizontal velocity components are proportional to $\frac{Sd_n}{d\theta}$ and $\frac{1}{\sin\theta}\,\frac{dS_n}{d\varphi}$ respectively. As an example, Fig. 2 shows the horizontal velocity pattern for the fifth degree sectorial harmonic, which is thought to be prominent in the present flow in the mantle[7,11]. It will be seen that there are five lines of longitude from which flow diverges: these would be lines along which tension would develop causing the formation of the central rifts in the rises, which have been found in the Atlantic and

Carlsberg ridges. But, because of the fact that the divergence of the velocity vector is zero, the components of flow along a ridge line cannot be zero all along the ridge. This is clear from Fig. 2, which shows that along the ridge in the southern hemisphere there is a southward component of flow parallel to the ridge and in the northern hemisphere a northward component. Only on the equator at intervals of 36° of longitude does the horizontal flow completely vanish. These are above the main rising and falling columns of fluid.

It is thus necessary to determine from the ocean bottom topography where these points are before examining if they have any relation to the negative and positive gravity anomalies. The ocean rise is therefore a line from which flow diverges but having, in general, a component of flow along it. The positions of the rising columns are therefore to be located at the intersection of two oceanic rises. For at this point the foregoing condition for an ocean rise, that is, that the velocity perpendicular to it is zero, results in zero horizontal velocity. Fig. 1 shows the distribution of the ocean rises after Menard[9]. There are five clear cases where the ridges bifurcate or sharply change direction: (1) the intersection of the Pacific Antarctic rise with the rise running northwards into New Zealand, (2) the branching of the mid-Indian Ocean rise, (3) the join of the north and south Atlantic rises, associated with the east–west fractures near the equator, (4) the join of the East Pacific rise with the Pacific Antarctic rise, and (5) the northern extremity of the East Pacific rise in the Gulf of California.

Izsak[10] has recently published a map showing the 10-m contours of the satellite geoid heights. These are ovals surrounding four points of maximum and five of minimum gravity. Fig. 1 shows the nine positions of these maxima and minima, their magnitudes and the contours surrounding them. It will be seen that a good correlation exists between the five points of minimum gravity and the five points of uprising currents determined from the topography. As this satellite gravity map is based on only those harmonic terms up to and including the fourth degree and as the fifth is of equal importance with the third and fourth in the spherical harmonic expansion of the Earth's topography, the correlation is as good as it is reasonable to expect. Doubtless the inclusion of higher harmonic terms will move the points of maximum and minimum gravity to some extent.

On this view we would naturally associate the positive anomalies with the descending currents and therefore with zones of compression. The two zones of positive anomaly in south Europe and the Andes agree with this expectation very well. The elongated positive anomaly between the mid-Pacific and the East Indies[12] covers a region of strong compression discovered by Vening Meinesz and the Tonga trench. The positive anomaly south of South Africa is of considerable interest, for little is known of the topography of the ocean floor in this region and points the need for investigation there.

It will at once be objected that the Tertiary mountain chains other than the Alps and Andes are not associated with positive anomalies. However, we must recall that on the theory of continental drift some continents have moved considerable distances in the past million years. Palæomagnetic evidence suggests that both India and Australia have moved considerable distances northward in this time. Both are now north of negative gravity anomalies and will still be experiencing a further northward force which may explain the Himalayas. Similarly, North America lies between two regions of uprising currents which must be exerting compressive forces which may have a fundamental connexion with the Rocky Mountain orogenies.

I thank Dr. H. W. Menard and Dr. R. W. Girdler for many discussions on the significance of the ocean ridges and Dr. J. H. Parry and Mrs. B. Gray for help with Fig. 2. I was stimulated to think about the problem presented by the gravity data discussion during a U.S. National Science Foundation conference on artificial satellites at the Virginia Polytechnic Institute, Blacksburg, Virginia, and with Dr. R. Kershner and his colleagues at the Applied Physics Laboratory, Silver Springs, Maryland.

OBITUARY

Dr. W. J. Dowson

WALTER JOHN DOWSON, who was widely known for his research and teaching in plant pathology, died recently in Cambridge at the age of seventy-six. His career had been unusually full and varied. Originally a Scholar of Christ's College, Cambridge, he obtained first-class honours in the Natural Sciences Tripos, and followed this by two years' research in Germany. Then in 1913 he went as Government mycologist to Kenya, where he is remembered for his work on control of the coffee leaf rust fungus, *Hemileia vastatrix*. In 1920 he returned to Great Britain as mycologist to the Royal Horticultural Society at Wisley, where he published work on a variety of diseases caused by fungi. In 1928 he went abroad again, this time as Government plant pathologist in Tasmania, where his human qualities and professional ability combined to make him a great success with the growers.

The year 1932 marked a significant divide in Dowson's professional life, for the twenty years remaining until his official retirement, he was to be both a university teacher and a more specialized research worker in a field that he was to make peculiarly his own. As a student at the Cambridge Botany School, he had early attracted the attention of Prof. F. T. Brooks. When, around 1932, a generous benefaction from the Rockefeller Foundation enabled a University Sub-Department of Mycology to be established within the Botany School, Brooks secured the appointment of Dowson as a University lecturer and as his colleague in the new Sub-Department. From that time until Brooks's retirement from the chair of botany in 1948, the two of them were responsible for all the teaching and research in mycology, bacteriology and plant pathology carried out in the Botany School, and both will long be remembered by their former research students, now all over the world.

After consultation with Brooks on his return to Cambridge, Dowson decided to take up the investigation of plant diseases caused by bacteria—at that time a decidedly neglected branch of plant pathology. This was a far-sighted decision, for the next twenty years and more, Dowson and his research students added greatly to our knowledge of these diseases. He was not content to confine himself to bacterial diseases occurring in Britain but extended his investigations to tropical plant pathogens, and carried on a voluminous correspondence with plant pathologists all over the world Third-year students at the Cambridge Botany School benefited by a facility not available elsewhere in Britain—a comprehensive course of lectures and practical work devoted to bacterial pathogens of crop plants Dowson's book, *Manual of Bacterial Plant Diseases*, first published in 1949, was the direct outcome of this course, as the most concise and readable text on this group of pathogens, it enjoyed a wide success In 1957 a second edition was published, this time by the Cambridge University Press, under the title *Plant Diseases due to Bacteria*

When Brooks retired from the chair of botany in 1948, Dowson became the second director of the Sub-Department of Mycology, and continued as such until his own retirement in 1952 He did not retire from research, however, but continued active in laboratory work and in publication almost to the time of his death eleven years later He will be remembered not only for an impressive contribution to his own subject, but also as a man who was inspired by lasting enthusiasm for his work purely for its own sake His scientific merit was recognized by the University of London through its award of the D Sc degree; later, he also obtained the Sc D., of Cambridge He did not, perhaps, receive his full share of the material benefits and public recognition to which his scientific achievements had undoubtedly entitled him For this, there could have been two reasons First Dowson only began his best work after reaching the age of forty-five, and his international reputation came considerably later. Secondly, he was an extremely modest and even somewhat diffident man , people who did not know him or his work well were somewhat surprised to be told that his system of classification for plant pathogenic bacteria had gained such ready acceptance What Dowson perhaps lost in his reluctance to thrust himself forward, he undoubtedly gained in human relationships A most kindly man, with an ever-ready and generous interest in the affairs of other people, he never lost the common touch which had made him as popular with the apple-growers of Tasmania as with a generation of students at Cambridge

NEWS and VIEWS

The 1963 Nobel Prize for Physics and Chemistry

ONE-HALF of the 1963 Nobel Prize for Physics has been awarded jointly to Prof Maria Goeppert-Mayer, professor of physics in the University of California, and Prof J Hans D Jensen, professor of theoretical physics in the University of Heidelberg, the other half has been awarded to Prof Eugen P Wigner, professor of mathematical physics in Princeton University The Chemistry Prize has been awarded jointly to Prof Karl Ziegler, of the Institute for Carbon Research, Mullheim-Ruhr, and Prof Giulio Natta, of the Institute of Technology, Milan

The Royal Society of London: Medal Awards

THE following awards of medals have been made by the President and the Council of the Royal Society *The Copley Medal*, to Sir Paul Fildes, formerly director of chemical bacteriology at the Medical Research Council, for his pioneer contributions to bacteriology, *The Davy Medal*, to Dr E J Bowen, Aldrichian praelector in chemistry at the University of Oxford, for his distinguished work on the elucidation of photochemical reactions, and for his study of fluorescence and phosphorescence in relation to the molecular processes concerned, *The Hughes Medal*, to Prof F C Williams, professor of electrical engineering in the University of Manchester, for his distinguished work on early computers, *The Leverhulme Medal* (which was founded in 1960 by the Trustees of the Leverhulme Trust Fund to mark the occasion of the tercentenary of the Royal Society), to Dr A J P Martin, director of the Abbotsbury Laboratories, Ltd , for his distinguished and fundamental discoveries in chromatography and its application

Rutherford Memorial

UNDER the terms of the scheme to commemorate the late Lord Rutherford of Nelson, the following appointments have been made Sir George Thomson, formerly Master of Corpus Christi College, Cambridge, as Rutherford Memorial Lecturer, to lecture in August 1964 in New Zealand Mr H S Tan, formerly of Imperial College of Science and Technology and later at the Post Office Research Station, Dollis Hill, to hold a Rutherford Scholarship for three years from September 1963, to carry out research in the department of physics, McGill University, in solid-state physics

Research Professorship

THE title of a Royal Society Research Professor has been given to Dame Honor Fell, Messel Research Fellow from 1931 until 1943 and Foulerton Research Fellow since 1943 Dame Honor Fell, who is director of the Strangeways Research Laboratory, Cambridge, is well known for her work in the field of cell biology

Visiting Professorship

DR A M. LWOFF, of the Institut Pasteur, Paris, has been appointed to be the Royal Society Visiting Professor for the academic year 1964–65 He is expected to take up appointment in April 1965 and to work in the division of virus research at the National Institute for Medical Research, Mill Hill, London, N W 7 Dr Lwoff, who is a Foreign Member of the Royal Society, is distinguished for his work on the morphology and nutritional requirements of Protozoa, and for his researches on lysogenic bacteria and bacteriophage Recently he has become interested in the growth of animal viruses and in normal defences against virus replication

Guests

ACADEMICIAN E N PAVLOVSKII of the Academy of Sciences of the U S S R and his daughter Dr. Irena Bykhovskaya-Pavlovskaya arrived in London on October 31 for a stay of three and a half weeks as the guests of the Royal Society, collaborating with the British Council The visits have been arranged under the agreement between the Royal Society and the Academy, which provides for the annual exchange visits of five senior scientists Pavlovskii became an Academician in 1939, and in 1944 he became an Academician of the Academy of Medical Sciences of the U S S R He is director of the Institute of Zoology and Parasitology of the Academy, lieutenant-general of medical services, president of the Geographical Society of the U S S R and an Honorary Fellow of the Royal Society of Tropical Medicine and Hygiene While in Britain, Academician Pavlovskii and his daughter will visit universities and other scientific institutions in London, Edinburgh, Liverpool and Cambridge They will both deliver a series of lectures

Imperial College of Science and Technology, University of London

THE day after the publication of the Report of the Committee on Higher Education, Lord Robbins, the chairman, was the Special Visitor at the annual Commemoration Day ceremony of Imperial College held recently in the Royal Albert Hall (see p 621 of this issue). That the College itself is poised on the threshold of a new epoch and ready to accept another challenge is evident from the report by Sir Patrick Linstead, the Rector The initial target of 3,000 full-time students has been reached. The figure includes 1,175 postgraduates and 120 women students New targets will soon be set and double the number of women will be welcome The academic staff now numbers more than five hundred and has been strongly reinforced at all levels, particularly at the top, where the recruitment of several outstanding men contrasts with gloomy utterances on the emigration of scientists

A radical change in the structure of the College is that 20 per cent of the students are in residence compared with 8 per cent last session More than six hundred students live within a quarter of a mile of the Queen's Tower of the College At the beginning of the term, H R H The Princess Margaret launched the great addition to the residential and social facilities in Prince's Gardens. A most welcome anonymous benefaction of a quarter of a million pounds will make it possible to build the next hall of residence in the same area, where a long-term plan is gradually taking shape The main task of demolition is over Two major building projects were finished last year—the Civil Engineering building and the South Side building in Prince's Gardens Four large academic building projects are now in hand

Dunn Nutritional Laboratory, Cambridge:

Dr. L. J. Harris

DR LESLIE J HARRIS, who became the first director of this laboratory on its inception by the Medical Research Council in 1926, retired on August 29 A native of Liverpool, and a graduate of the University of Manchester, he went to Cambridge as a young research student under the late Sir Frederick Gowland Hopkins There he soon won distinction, and in 1925 the Meldola Medal of the Institute of Chemistry, for his pioneer work in applying the theory of titration curves to amino-acids, polypeptides and proteins His ingenuity enabled him to distinguish clearly between zwitterion and non-zwitterion molecules After his appointment at the Dunn Nutritional Laboratory his interests were concentrated on vitamins He originated the assessment of human nutritional status, by saturation tests, and also the bradycardia test, with rats, for thiamin deficiency He developed chemical methods commonly used for the assay of ascorbic and nicotinic acids, discovered 'monkey pellagra', and made illuminating investigations with rats on the mechanism and psychology of appetite During the Second World War he supervised joint work between the Medical Research Council and the Food Investigation Board on methods for the preservation of foods, usually by dehydration, without the excessive destruction of their vitamins He played a large part in the foundation of the Nutrition Society (Great Britain), of which he was the first honorary secretary (1941–47) and later president (1953–56) He was also a joint founder and secretary-general (1946–60) of the International Union of Nutritional Sciences, a body which has held six highly successful triennial congresses, most recently in Washington (1960) and Edinburgh (1963) His semi-popular book, *Vitamins in Theory and Practice*, has been widely read and translated into several languages To mark the completion of his long period as director, Dr Harris was presented, by present and past members of his staff, with his portrait, painted in oils by Mrs B J Miles

Dr. E. Kodicek

DR EGON KODICEK has been appointed to succeed Dr Harris Dr. Kodicek has been working at the Dunn Nutritional Laboratory since 1939. He graduated M D. in Prague in 1932 and later became assistant physician at the Department of Internal Medicine at Charles University. In 1938 he was appointed physician-in-charge of the Endocrinological Out-patient Unit In the same year he was awarded the Diploma of Specialist for Diseases and Metabolic Disorders Dr. Kodicek came to Britain in 1939 as a Scholar of the Society for the Protection of Science and Learning He obtained the Ph D degree of the University of Cambridge in 1942 for his thesis *Biochemical Studies on Nicotinic Acid* The same year he was appointed a member of the Scientific Staff of the Medical Research Council. During the War he took part in investigations on the effects of dehydration on the vitamin B content of foodstuffs and was a member of various Government sub-committees Since the War, Dr Kodicek has carried out experimental work on a wide range of topics which have included bacterial metabolism and the effect of ascorbic acid deficiency on wound healing He has also made investigations into the nature of bound nicotinic acid and its relation to the pathogenesis of pellagra More recently, Dr Kodicek has made an exhaustive study of the distribution and metabolism of vitamin D in the animal body, this work was greatly facilitated by his successful synthesis of ^{14}C-labelled vitamin D Dr Kodicek has been a visiting lecturer to a number of universities in the United States and was elected a Committee Member of the Biochemical Society in 1961

Inorganic Chemistry in the University of Sheffield

Prof. R. Mason

PROF RONALD MASON, who was recently appointed to the newly established chair of inorganic chemistry in the University of Sheffield, took up his duties there on October 1 Dr Mason began his scientific career by taking a first degree at University College, Cardiff, and thereafter studied under Dame Kathleen Lonsdale at University College, London, obtaining his doctorate in 1953 in crystallography For the next seven years he was Research Fellow of the British Empire Cancer Campaign in the Department of Chemistry at University College and undertook research work into the structure of biologically active molecules, X-ray studies of thermal vibrations and the applications of quantum chemistry to problems in molecular biology From 1960 he was lecturer in inorganic chemistry in the Imperial College of Science and Technology, London His more recent work has been concerned with structural investigations on a variety of transition metal complexes, notably those where there is both σ- and π-bonding, and on paramagnetic anisotropies of single crystals of tetrahedral cobalt(II) species, potassium ferricyanide and di-π-*cyclo*pentadienyl nickel and their relation to the electron distribution in these complexes He has also had a continuing interest in energy and charge migration phenomena in molecular solids and biological systems

Prof Mason is the author of some fifty research papers and co-editor of the series *Advances in Crystallography*, *Advances in Radiation Biology* (to appear shortly) and of *Physical Processes in Radiation Biology*, and he has been visiting research professor in the Department of Biophysics at Michigan State University and visitor to the Brookhaven National Laboratory, Upton, Long Island The understanding of modern inorganic chemistry is especially dependent on structural analysis, and Prof Mason's expert knowledge in this area, coupled with his theoretical background and broad interests, should enable his new University to develop a thriving school of contemporary inorganic research in the widest sense

The Rockefeller Foundation

A statement, *Plans for the Future*, issued by the Trustees of the Rockefeller Foundation, indicates that, as was foreshadowed in the recent annual report of the Foundation (see *Nature*, 200, 97; 1963), during the foreseeable future the Foundation's efforts will be concentrated in five areas of pressing need. Three of these—the strengthening of that part of the present programme which is directed to human nutrition, and involving increasing the quality and quantity of food, as well as the search for new knowledge leading to more efficient use of land and water resources; initial research on the population problem, including programmes on the dynamics and the stabilization of populations; and strengthening selected centres of learning in the emergent nations—were specifically mentioned in that annual report. To these are now added programmes designed to give increasing numbers of citizens better educational opportunities to develop their full potential and to take their rightful place in society. Moreover, programmes are included to aid cultural development in the humanities and the creative and performing arts, using selected colleges and universities as the principal media. In its efforts toward these five goals—provision of an adequate food supply, stabilization of population, the training of promising individuals and development of institutions in areas where lack of leadership retards progress, advancement of equality of opportunity for all, and cultural development—the Foundation will, as it has traditionally done, seek to sharpen definitions of the problems and to support promising pilot projects which may open the way for greatly expanded organized effort.

The Nuffield Foundation Science Teaching Project

Criticism of school science courses is nothing new. Changes in content and a more experimental approach in the teaching have been advocated in many quarters for decades. The present wave of dissatisfaction has swept into Europe from across the Atlantic and with it has come the idea of a combined operation to set science teaching on a new path. The Nuffield Foundation Science Teaching Project is one such operation, and the first *Progress Report* gives some idea of its scope (Pp. iii+40. London: The Nuffield Foundation, 1963). It aims, initially, to produce a range of teaching resources—texts, teachers' guides, visual aids, apparatus and laboratory notes—for each of four courses. These are biology, chemistry and physics for 11–16-year-olds and science for 9–13-year-olds. Stress is laid on the encouragement of critical enquiry. Some indication is given of the approach planned and one is pleased to note that, while subject-matter is to be selected for its relevance to "the understanding of science as it is to-day" and with the educated layman in mind, there is a recognition of the danger of building up "a picture of science by authority". The chemistry section underlines the need for clear distinction between experimental fact and theoretical explanation, a distinction too easily blurred in the chase for modern knowledge, and a similar feeling is expressed in the biology section by reference to the practical evidence on which generalizations are based. Preparation has been made for trying out materials in schools, and a list of these, the teachers and others involved in the project, is included. The appearance of the actual teaching materials will be awaited with interest.

Economic Growth and Manpower

The report of the 1963 spring conference of the British Association for Commerce and Industrial Education presents the preliminary findings of a group of economists who, for the past two years, have been constructing a computable model of the British economy at the Department of Applied Economics of the University of Cambridge (Pp. 55. London: British Association for Commerce and Industrial Education, 1963. 10*s*.) The objective of the group is to investigate the problems of increasing the rate of British economic growth. As the work progresses every effort is being made to discuss its various aspects with those engaged in practical activities so that the results are both realistic and consistent. As one of its contributions to National Productivity Year, the Association provided a platform for discussion of the results which are now beginning to emerge from the group's calculations. Prof. R. Stone, P. D. Leake professor of finance and accountancy in the University of Cambridge, stated that "If we are to reach the goal proposed by the National Economic Development Council . . . we need to see clearly, quantitatively and with as much notice as possible, what is expected of each of us . . . A small group cannot produce a finished picture in one go from published information: it needs the help of other groups and individuals engaged in practical life, who alone can contribute the necessary range of knowledge and experience. But all this knowledge must be organized within a coherent framework . . . Until a framework exists, the task of organization cannot be started". The three economists who followed at the conference covered: (*a*) Industrial outputs in 1970—how the model is used to estimate the levels of output which each industry will have to attain by 1970 if the programme of growth is to be realized. (*b*) Industrial requirements for manpower in 1970—estimates under (*a*) interpreted into manpower requirements for thirty-one industries (the estimate for 1970 is 21,482 million as opposed to 20,469 million in 1960). (*c*) The composition of manpower requirements—the spectrum of skills; labour skills in 1951, in 1961 and in 1970. Each paper is accompanied by appropriate diagrams.

Fauna Conservation

The latest issue of *Oryx* (7, Nos. 2 and 3; August 1963) contains reports on several species of mammals that are thought to be in need of special protection because of their diminished numbers. A survey in southern Nepal by E. P. Gee shows that the population of Indian rhinoceros in the adjacent valleys of the Rivers Rapti and Rue is now increasing. The estimated number of 300 rhino in Nepal in 1959 dwindled to 160 in 1961 owing to increased poaching during a time of political unrest. By 1962 after the re-establishment of more settled conditions the number had risen to 185. The author recommends additions to the area of the national park, vigorous suppression of poaching, and the encouragement of tourism, as measures to ensure the conservation of the species. A paper by Dr. and Mrs. Colin Bertram states that the manatee is now seen less frequently in the waters of British Guiana than formerly, but that its status is not easy to assess because the animals are shy and difficult to observe; the increasing use of power boats may be driving them from some reaches of the rivers. Research is needed into the biology of the manatee, particularly its breeding, about which almost nothing is known. Manatees are efficient clearers of canals and channels choked with aquatic vegetation, but their introduction into other parts of the world to clear more open waters cannot be practicable until much more is known about them. Barbara Harrisson gives an interesting account of the attempt to return to the wild orphaned orang-utans seized from illegal captivity. The experiment has achieved some success owing to the zeal and devotion of Mrs. Harrisson, but the real way to conserve rare animals in the wild is to leave them alone and ensure that nobody interferes with them.

Radioactive Contamination of Food in the United Kingdom

The annual report for 1962–63 of the Agricultural Research Council Radiobiological Laboratory, Wantage, has recently been published (*ARCRL* 10 Pp x+108 London Agricultural Research Council Obtainable from H M S O 7*s* 6*d* net) It is the tenth in the series of reports on the Laboratory's work on radioactivity in the diet The Radiobiological Laboratory has continued to measure the levels of iodine-131, strontium-89, strontium-90, cæsium-137 and barium-140 in foodstuffs in the United Kingdom The major effort was devoted to milk, samples being regularly examined from depots which handle more than 40 per cent of Britain's total production The average ratio of strontium-90/calcium in milk was 12 picocuries/g in 1962, about 13 pc /g for the twelve months to the end of March 1963, and about 15 pc /g for the twelve months to the end of June Those levels reflect the increased rate of fall-out in 1962, and at the end of the year the twelve-month average was about 20 per cent greater than the previous highest value recorded in 1959 following the 1958 nuclear tests The average ^{90}Sr/Ca ratio in the total mixed diet in 1962 was 10 pc /g, which was about 60 and 10 per cent higher than in 1961 and 1959, respectively, but was still less than 8 per cent of the 'cautionary' working-level of 130 pc /g recommended by the Medical Research Council However, not all the components of the diet reflected the increased rate of fall-out in 1962 In particular, the ^{90}Sr/Ca ratio for flour was below that for the previous year due to the delay between the harvest of grain and the consumption of the flour The values rose, however, in the 1962 crop, which did not enter the diet until 1963 The levels of iodine-131 in milk for the first six months of 1963 continued to be below the limit of detection (11 pc /l) The average for the twelve months to the end of June was below 15 per cent of the Medical Research Council's recommended 'cautionary' level of 130 pc /l

One-sided Tolerance Limits and Variables Sampling Plans

A MONOGRAPH recently published by the Sandia Corporation contains a wide selection of tables based on the non-central *t* distribution (*SCR*–607 *Factors for One-sided Tolerance Limits and for Variables Sampling Plans* By D B Owen Pp 412 Albuquerque, New Mexico Sandia Corporation. Available from Office of Technical Services, Department of Commerce, Washington 25, D C , 1963 5 dollars) Previous work in this field has thus been extended and, in some cases, corrected. Sampling from a normal distribution is considered throughout, the principal tables are designed for use with acceptance procedures (single-sample variables sampling plans) described in the author's abstract as follows "The probability is γ that at least a proportion P of a normal population is below $\bar{x} + ks$, where $\bar{x}$ has a normal distribution with mean μ and variance σ^2/n and fs^2/σ^2 has an [independent] chi-square distribution with f degrees of freedom" Typically γ and P are fixed according to manufacturer and consumer interests Values of k are tabulated for suitable values of γ, P and the sample sizes n and f Other applications include the power of Student's *t*-test and "expected coverage tolerance limits" The tables are balanced by a valuable commentary In this, Dr Owen explains very clearly how to use the tables, he discusses various approximations arising in their construction, and he gives the mathematical derivations on which they rest Dr Owen claims that the variables sampling plans discussed are to be preferred in particular, when the protection of the consumer is of primary interest and the costs of items are high He does not argue this point, but the reader who feels at all doubtful is free to seek reassurance by sampling the bibliography of some eighty items

The Night Sky in December

NEW moon occurs on Dec 16d 02h 07m U T and full moon on Dec 30d 11h 04m The following conjunctions with the Moon occur Dec 18d 14h, Venus 0 5° S , Dec 20d 14h, Saturn 2° N., Dec 24d 08h, Jupiter 4° N In addition to these conjunctions with the Moon, Mercury is in conjunction with Mars on Dec. 7d 03h, Mercury being 1 4° S , and Mercury with Mars on Dec 30d 05h, Mercury being 2° N There is a total eclipse of the Moon on December 30, invisible at Greenwich Mercury is an evening star, but is not well placed for observation Venus is an evening star, setting at 17h 15m, 17h 40m and 18h 30m on Dec 1, 15 and 31, respectively Its stellar magnitude is −3 4, its distance decreases during the month from 141 to 128 million miles, and the visible portion of the apparent disk decreases from 0 914 to 0 862 Mars is too close to the Sun for observation Jupiter sets at 2h 20m, 1h 20m and 0h 25m on December 1, 15 and 31, respectively It is in Pisces, its stellar magnitude is −2 2 and its distance from the Earth on December 15 is 425 million miles Jupiter is stationary on December 6, after which it resumes its eastward motion among the stars Saturn sets about 4h after the Sun, but conditions for observation are now becoming unfavourable Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich Dec 2d 1h 20 6m, ζ Tau (*D*), Dec 2d 2h 19 0m, ζ Tau (*R*), Dec 29d 2h 18 6m, 106 Tau (*D*) *D* and *R* refer to disappearance and reappearance, respectively. The Geminid meteors are active during December 9–14, with maximum on December 13, the radiant is near R A 7h 28m, Dec +32°, and conditions for observation are favourable The Ursid meteors are active during December 20–22, with maximum on December 22, the radiant is near R A 14h 28m, Dec +76°, and conditions for observation are favourable The winter solstice occurs on Dec 22d 14h

Announcements

PROF C F A PANTIN, professor of zoology in the University of Cambridge, president of the Marine Biological Association and a member of the Nature Conservancy, has been appointed chairman of the newly constituted Trustees of the British Museum (Natural History) Prof Pantin, who was awarded the Royal Medal of the Royal Society in 1950, and was President of the Linnean Society from 1958 until 1960, is distinguished for his work in marine biology and experimental zoology, and well known for his interest in providing the broadest possible basis for future specialists

AT a general monthly meeting of the members of the Royal Institution held on November 4, the Right Hon Lord Brabazon of Tara was appointed honorary professor extraordinary of the Royal Institution Lord Brabazon has been a Member of the Institution for twenty years and was president for fifteen years from 1948 until 1963 He was succeeded as president by Lord Fleck

A MEETING of the Plant Phenolics Group on "Polysaccharides" will be held at the School of Pharmacy, London, on January 7 Further information can be obtained from Mr A H Williams, Research Station, Long Ashton, Bristol

A COLLOQUIUM on "The Decomposition and Ignition of Peroxides", organized by the Combustion Institute, will be held in the University of Oxford on January 7 Further information can be obtained from Dr W G Parker, Department of Chemistry, College of Advanced Technology, Birmingham 4

THE 1964 Winter Gordon Research Conferences on "Polymers" and "Electrochemistry Electrode Reactions" will be held in Santa Barbara, California, during January 27–February 7 Further information can be obtained from the director of the conferences, Dr W George Parks, University of Rhode Island, Kingston, R I

THE ROWETT RESEARCH INSTITUTE FOR ANIMAL NUTRITION

GOLDEN JUBILEE

THIS year the Rowett Institute celebrates its origin in 1913, when a Joint Committee of the University of Aberdeen and the North of Scotland College of Agriculture was formed for the prosecution of research in animal nutrition The late Prof E P Cathcart, who in 1913 was a lecturer in the Institute of Physiology in the University of Glasgow, was first approached and accepted the offer to go to Aberdeen to start this research work Later, he decided to take a chair of physiology in the University of London and, when intimating his change of mind, recommended that Dr John B Orr be offered the post Thus, Dr Orr became the first director of what not long after grew into the scale of an institute, and in this capacity he served until his retirement in 1945, when he was succeeded by Dr D P Cuthbertson, also from the Institute of Physiology, Glasgow, but who had been seconded at the time to the Medical Research Council During its fifty years, therefore, the Institute has had only two directors

The Governing Body of the Institute is now tripartite, with five persons appointed by each of the following University of Aberdeen, North of Scotland College of Agriculture and the Secretary of State for Scotland The Principal and Vice-Chancellor of the University is its chairman

Following his retirement in 1945, Sir John Orr became the first director-general of the Food and Agriculture Organization of the United Nations The need for the creation of such an organization owed much to Orr's vision and his previous researches culminating in his book *Food, Health and Income* Orr had also been responsible for a large-scale demonstration of the nutritive value of milk for children, and the evidence from this and comparable trials was largely responsible for the introduction of the milk and finally the meals-in-schools scheme He had felt that so much useful knowledge had been acquired about animals that it was time it was applied to man himself

The Commonwealth Bureau of Animal Nutrition does not share the Jubilee that the Rowett Institute is celebrating it is only thirty-two years old, but, as in some ways an offshoot of the Institute, it shares its history and celebration, for Orr was its first director, followed in more recent years by Dr I Leitch and Dr D Harvey The present director of the Institute is consultant director to the Bureau and editor-in-chief of its publication, *Nutrition Abstracts and Reviews*

The early and subsequent history of the Institute, its Reid Library, its farm—the Duthie Experimental Stock Farm—and its residential hall—Strathcona Club—are described in a unique volume entitled *Progress in Nutrition and Allied Sciences*, which is edited by the present director and published by Oliver and Boyd at the modest price of 50*s* for its 452 pages (*Nature*, 200, 201, 1963) This provides an account of the present research work of the Institute in relation to the existing state of knowledge, and some account is also woven into it of the past research of the Institute A few distinguished ex-members of staff have contributed topics not at present being investigated at the Institute There are thirty-nine chapters Among the significant topics dealt with are those which have been in recent years the continuing concern of the Institute These are the physiology, biochemistry and microbiology of digestion, particularly in the ruminant, the nutritional significance of the 'non-protein nitrogen' fraction of plants, physiological individuality, minerals in relation to the skeleton, the teeth and functioning of the nervous system, mammalian glycosidases and their inhibition, growth and reproduction, family diets, infection and resistance The Institute's present contribution to our better understanding of the nutrition of dairy cattle, sheep and their shelter, poultry and pigs and the recent system for intensive beef production introduced in Britain by the Institute are also described The Institute continues to assist in defining where the application of man's scientific knowledge of agriculture to world needs can best be directed

The present staff of the Institute numbers two hundred and fifty persons, of whom some fifty-five belong to the scientific officer class Dr R L M Synge, Nobel prizeman, is probably its most distinguished member of staff He has written a challenging article on the state of our ignorance concerning the nutritional role of the constituents of the non-protein fraction of plants at this point in time

The Institute publishes each year an annual report which is free to universities, colleges and non-commercial research organizations

At its Founders' Day Dinner in this year of its Golden Jubilee, the Secretary of State for Scotland, the Right Hon Michael Noble, gave the principal speech and proposed a toast to "The Founders"

D P. CUTHBERTSON

VEGETATION OF THE HUMID TROPICS

A SYMPOSIUM on the vegetation of the Humid Tropics was held at Kuching, Sarawak, during July 2–10, it was sponsored jointly by the South-east Asia Science Co-operation Office of Unesco and the Government of Sarawak, and was attended by some 36 participants coming from most of the countries of South-east Asia, as well as from Europe, the United States and Australia The United States was represented by Dr F R Fosberg of the Pacific Vegetation Project, Washington, chairman of the Humid Tropics Committee of Unesco, and by Dr George Gillett of the University of Hawaii; participants from the United Kingdom were Sir George Taylor, director of the Royal Botanic Gardens, Kew, Mr P Greig-Smith, reader in botany at the University College of North Wales, Bangor, and Prof P W. Richards. Mr L. Mattsson, director of the South-east Asia Office at Djakarta, was the official representative of Unesco This symposium was the third of a series on tropical vegetation organized by the South-east Asia Office of Unesco and followed those held at Tjiawi, Java, in 1958, and at Goroka, New Guinea, in 1960 (see *Nature*, 189 24, 1961)

The present policy of the South-east Asia Science Co-operation Office is that each symposium should have one or more principal themes, as well as giving experts on tropical vegetation the opportunity of discussing their work and problems with colleagues whom of necessity they cannot meet very often At the Goroka symposium, the Proceedings of which have recently been published*, the emphasis was on the impact of man on the vegetation of the humid tropics At the recent symposium at Kuching the chief themes were recent advances in tropical ecology and the application of quantitative methods to the study of tropical vegetation Although according to the programme the latter topic was the subject of only one morning's session, it was in fact a recurrent theme, both in the regular sessions and in the less formal, but no less animated, discussions 'out of hours' The papers presented to the symposium indeed covered a wide field, from the "Entropy Concept in Ecology" (F R Fosberg) to the "Ecology of Pitcher Plants (*Nepenthes*)" (B E Smythies), and provided a cross-section of the main fields of activity in present-day tropical ecology

---

* Unesco Science Co operation Office for South-east Asia and Administration of the Territory of Papua and New Guinea (Government Printer, Canberra, 1963)

Sir Alexander Waddell, Governor of Sarawak, declared the symposium open at an inaugural session in the afternoon of July 2, under the chairmanship of Mr B E Smythies, conservator of forests, Sarawak In his speech the Governor stressed the importance of ecological research to a country such as Sarawak, much of which consists of undeveloped land covered with forest and other vegetation in a relatively natural state He also quite rightly directed attention to the considerable contribution to research on tropical vegetation which is being made by the staff of the Sarawak Forest Department

The one session devoted entirely to quantitative methods was opened by Mr P Greig-Smith, who strongly emphasized the importance of statistically reliable sampling procedures and directed attention to some of the pitfalls which surround attempts to apply quantitative methods of description and analysis to plant communities as rich in species and lacking in homogeneity as the forests of the humid tropics, he also discussed the problems involved in the selection and delimitation of sample plots. The type of quantitative method to be used must be modified, Mr Greig-Smith considered, to suit both the nature of the vegetation to be studied and the ultimate object in view This opening paper led to a long and lively discussion in which many modern techniques such as 'plotless sampling', gradient analysis, etc , were considered

This paper was followed by two others dealing with related problems Dr P S Ashton gave an account of his work (shortly to be published as an *Oxford Forestry Memoir*) on the Mixed Dipterocarp forests of Brunei The forests of this small country—no larger than an English county—are extraordinarily rich in species, there are more than 150 species of large trees belonging to the family Dipterocarpaceae alone Dr Ashton has, however, successfully used a modification of Bray and Curtis's ordination technique and shown that the varying composition of the forest community reflects very sensitively the innumerable small variations in topography, soil and local climate This paper high-lighted the extreme complexity of some plant communities of the humid tropics, but also gave reason for hoping that relatively simple quantitative techniques might prove adequate in providing a firm basis for correlating the endless and seemingly random variations of forest composition with the factors of environment The last paper in this session was read by Mr A J Vincent of the Forest Research Institute, Kepong, Federation of Malaya, and was entitled "Tropical Rain Forest Ecology What Does the Forester Need to Know About It and How Should He Put the Necessary and Sufficient Knowledge on a Quantitative Basis ?" As might be guessed from its title this paper was valuable in bringing the somewhat academic approach to tropical ecology which had prevailed earlier in the discussion into relation with practical realities in the newly independent countries of south-east Asia at the present day

Quantitative problems of other kinds were raised in several other papers notably in one by Mr D I Nicholson of the Sabah (North Borneo) Forestry Department on "Studies in Virgin Forest Near Sandakan, North Borneo" Among the many interesting problems raised in the discussion on this paper was the reliability of the various methods at present used for estimating the age of rain forest trees (which do not as a rule produce annual growth rings) Mr I M Qureshi (Dehra Dun) expressed the view that quantitative ecological methods should be, so far as possible, standardized as well as statistically valid

Another subject with which several papers were concerned and which led to much informal discussion was the relation between vegetation, soil and parent rock Dr L. J Webb, of the University of Queensland, in a paper on the rain forests of north-eastern Australia, directed attention to the well-known fact that in the humid tropical regions of Australia there is a marked difference between the vegetation on basalt and on other parent materials such as sandstone, the former bearing rain forest similar in many of its features to the rain forests on the Indo-Malayan region, the latter eucalypt forests of a characteristically Australian type In spite of this obvious difference in vegetation, however, soil analysis, at least using conventional methods, does not seem to reveal any marked differences in nutrient elements such as phosphorus, potassium and nitrogen between the soils formed from basalt and those derived from other parent materials A similar problem was discussed by Prof Richards in a paper dealing with soil conditions in some lowland forest communities in Brunei and Sarawak, where there are striking differences between the 'Heath forest' on the sandy *kerangas* (podsolic) soils and the Mixed Dipterocarp forests on soils of the more normal latosol type Here again the soils are obviously different and are clearly correlated with differences of vegetation, but the soil analyses appear to indicate very little significant difference in the amount of nutrients present in the soil The very distinctive character of 'Heath forest' communities was also brought out in a paper by Mr Anwari Dilmy (Herbarium Bogoriense) dealing with the vegetation of the Sampit area in Central Kalimantan (Indonesian Borneo)

It was worthy of note that although nearly every contribution to the symposium was concerned with the ecology of plant communities rather than with autecology, several speakers stressed the need for more work, especially experimental work, on the ecology of individual species Some sessions ranged into widely different fields, for example, one of the most interesting and informative dealt with palynology, a subject of great promise for the future understanding of tropical vegetation Dr D Walker of the Research School of Pacific Studies, Australian National University, Canberra, gave an account of his work on the stratigraphy of a swamp in the New Guinea highlands, and Mr J Muller, of Brunei-Shell Petroleum Co , summarized the results of his fascinating work on the pollen in Holocene peats in Sarawak In Borneo, a complete stratigraphical sequence from the Cretaceous to the present day is available for pollen analysis This has already revealed much of interest about the history of the mangroves and peat swamp, but what has already been discovered can be no more than a foretaste of results of immense significance for the understanding of the vegetation of south-east Asia

A paper by Mr T Smitinand on the vegetation of a limestone massif in Thailand and another by Dr J A R Anderson on the limestone habitat in Sarawak provided much new information on a very interesting type of tropical habitat which has hitherto received very little attention and also raised the issue of conservation which, though not one of the official themes of the symposium, was clearly one of the underlying anxieties of most participants The vegetation of the fantastically shaped limestone hills in Sarawak, Malaya, Thailand and elsewhere in south-east Asia is of the greatest interest to the botanist because of its strange and often endemic plant species, but there is a grave danger that because of the high economic value of limestone for making cement and other purposes, especially in relatively advanced countries such as the Federation of Malaya, the habitat will be destroyed before there is any adequate scientific knowledge of its flora and fauna. Similar anxieties were expressed about several other types of tropical vegetation, especially the lowland rain forest of the Malay Peninsula and the montane forests of Mount Kinabalu in North Borneo where the proposal to establish a national park needs to be pressed forward rapidly before the steady advance of shifting cultivation destroys any more of the forest vegetation.

Not the least important part of the activities of the symposium were the field excursions, which gave the opportunity for very valuable discussions of present-day problems in tropical ecology. The week at Kuching was interrupted by a very pleasant and interesting visit to the Bako National Park and Santubong Mountain at the mouth of the Sarawak River. The excellent living accommodation and well-designed paths at Bako gave the party an opportunity of seeing something of the unusual forest and heath-like plant communities on a low sandstone plateau on the coast, where *Nepenthes* and strange-looking epiphytic species of *Dischidia* and *Hydnophytum* grow in abundance and can readily be studied. Santubong at the mouth of the Sarawak river, memorable for its associations with Alfred Russell Wallace, provided a glimpse of the extraordinary variety of species and plant communities on a steep and isolated mountain less than 3,000 ft. high. Before leaving Kuching, members of the symposium were able to see the excellent 'natural' arboretum created by the Sarawak Forest Department in the Semengoh Forest Reserve and climb the 100-ft. tower which is being used to collect data on temperature and humidity at different levels in undisturbed dipterocarp forest. On the same day a short visit was paid to the famous limestone hills at Bau.

After the conclusion of the activities of the symposium in Sarawak, most of the participants were able to take part in a tour to Brunei, where one day was spent in studying the vegetation of the peat swamps and another in the magnificent Mixed Dipterocarp forest of the Andulau Forest Reserve. After this many of the party joined in a short visit to Sabah (North Borneo) and climbed Kinabalu (13,455 ft.) with its amazingly rich montane flora.

The success of the symposium owed much to the careful preparatory work of Dr. J. A. R. Anderson and other members of the Sarawak and Sabah Forest Departments, as well as to the simple, but very convenient, accommodation provided by the Sarawak Government at the Batu Lintang Teachers' Training College. The fact that it is possible to hold such a symposium at all underlines the increasing importance of tropical ecology. The foundation of a Society for Tropical Ecology in India, the formation of a Tropical Group in the British Ecological Society and the series of symposia sponsored by Unesco since the inauguration of its Humid Tropics Committee at Kandy in 1956, show that this interest is widespread and that an appreciation is developing of what ecology can contribute to scientific knowledge in a part of the world where most of the major problems are biological.

P. W. RICHARDS

ACTIVATION ANALYSIS IN MEDICINE AND BIOCHEMISTRY

ACTIVATION analysis is a sensitive and versatile technique for the determination of trace constituents through measurement of the radioactivity induced after bombardment by neutrons or other sub-atomic particles. First suggested by Hēvesy and Levi in 1936, it became practicable on a useful scale with the development of nuclear reactors and other neutron sources after the Second World War. A rapid growth of interest in biological applications was made evident during the third International Biological Colloquium, organized by the Commissariat à l'Energie Atomique and held at Saclay, near Paris, during September 26–28. The gathering of 150 research workers, drawn from many countries and many disciplines, heard 20 papers on recent developments and potential applications of the method in medicine and biochemistry.

Interest was equally divided between the experimental techniques and their applications. Discussion of techniques was concentrated on three major problems: (*a*) sources; (*b*) chemical manipulation of samples; (*c*) assay of induced radioactivity.

Thermal neutron activation is serviceable for the estimation of about 70 elements at sub-microgram levels. Consequently, the nuclear reactor is widely used as a source; most of the research reactors brought into operation in recent years, giving fluxes of 10^{11}–10^{12} n/cm^2/sec, are contributing to analytical research projects. A reactor is, however, not always essential or even desirable. For some elements the sensitivity of activation analysis using thermal neutrons is very low; for a few elements (near the beginning and end of the Periodic Table) the method is not applicable at all. Even when adequate sensitivity is available, interfering activities may be contributed by other elements present in the sample under examination. The estimation of manganese in blood can, for example, be achieved by using the reaction ^{55}Mn(n, γ)^{56}Mn. The small flux of fast neutrons inside a typical reactor will generate the same product by the reaction ^{56}Fe(n, p)^{56}Mn, giving an error of as much as 30 per cent. In this instance, a correction can be calculated, but the interference is sometimes of a more subtle kind, not so easily dealt with.

It is occasionally possible to secure greater sensitivity and accuracy by using fast neutrons. The most convenient source is a discharge-tube generator in which a tritium target is bombarded by deuterons accelerated to energies of 150–200 keV. Several models of neutron generators using this principle are available commercially, giving 14-MeV neutrons at fluxes of 10^7–10^9 n/cm^2/sec. W. Schulze (Free University of Berlin) discussed the use of fast neutrons in activation analysis and gave a comprehensive table of nuclear cross-sections (calculated and measured) for (n, γ), (n, p), (n, 2n) and (n, α) reactions. J. Wood (Services Electronic Research Laboratory, Baldock) reported new developments in the design of discharge tubes for the (d, t) reaction; with the further advances now in prospect, this work should make the use of laboratory neutron generators more attractive in terms of initial cost and tube life.

The use of charged particles for activation was exemplified in a report by A. Fleckenstein (University of Freiburg) on the determination of oxygen in biological materials, using the stable isotope oxygen-18 in the reaction ^{18}O (p, n)^{18}F, which gives excellent sensitivity. Recognition of the potentialities of activation analysis with protons or helium-3 ions has led to renewed interest in the cyclotron; it is hoped that a machine giving 8-MeV protons can be produced commercially in the United States for 100,000 dollars.

The rest of the discussion on techniques was concerned with the relative contributions of radiochemical manipulation and of instrumental assay. Broadly speaking, the activity under investigation may be separated chemically (using modifications of normal analytical procedures) or physically (by examination of the γ-ray spectrum of the induced radioactivity). In practice it is not always possible to achieve complete separation by either method alone. In biological materials, for example, the presence of sodium-24 in irradiated samples makes it difficult to measure the activity produced by trace elements present at very low levels

A lively discussion arose over the removal of interfering activities Ideally, the sample should be protected from all possible contamination until it has been irradiated, after that the purity of reagents and containers is of less importance Chemical treatment of the sample before irradiation is superficially attractive but potentially dangerous Prior separation by paper chromatography (with subsequent irradiation of the paper bearing the particular metabolic product or other compound to be analysed) is a serviceable technique in the study of complex biochemical processes, since the composition of the original tissue or product would be altered by destruction of chemical bonds during irradiation. Unfortunately the best available chromatographic paper includes impurities such as phosphorus and chlorine which limit the sensitivity of the method

Dialysis of experimental samples (such as blood) before irradiation is another attractive possibility, but the presence of contaminating trace elements in the dialysing fluids may lead to uncertainty Results obtained by this technique in the estimation of manganese in biological fluids were challenged during the Colloquium

If specimens of blood or other tissues are ashed before irradiation, some constituents may be lost by alloying in metallic crucibles or by fusion in ceramic vessels The heparin anticoagulant added to blood samples before ashing contains relatively large amounts of manganese and zinc, making the estimation of these elements difficult Even the storage of specimens in collecting bottles before irradiation may introduce contamination. Glass and polyethylene are suspect in this connexion, but 'Teflon' is more nearly inert The choice of containers for irradiation in the reactor is also important

When once the specimen has been irradiated, chemical treatment may be applied without fear of introducing contamination, though it is still important to estimate and correct for the chemical yield Ion-exchange, chromatography and dialysis are all useful at this stage in the analysis Rapid separation of the desired activity can sometimes be achieved by isotopic exchange W W Meinke (National Bureau of Standards, Washington) described a simple technique for the estimation of magnesium in blood, using a one-drop specimen After irradiation for 10 min at a thermal neutron flux of 10^{12} n/cm^2/sec the sample is brought into solution (by destruction of organic matter) and shaken for 2 min with a precipitate of magnesium ammonium phosphate The radioactive magnesium-27 then becomes concentrated in the precipitate by isotopic exchange The entire radiochemical procedure can be completed in 5 min—a necessary requirement, since the half-life of the activity to be examined is only 10 min

The speed and relative simplicity of chemical separations were emphasized by a number of contributors, but the instrumental approach, relying on γ-ray spectrometry, had convincing advocates The limit of present-day progress was illuminated by R E Wainerdi and his colleagues (Texas Agricultural and Mechanical University) Samples of biological material for activation analysis are assayed entirely by automatic instrumental methods The information obtained from a 256-channel pulse-height analyser, recorded on punched cards or magnetic tape, is transferred to an IBM 709 electronic computer in which the concentration of the element under consideration is calculated with the help of a calibration curve, obtained in advance from known amounts of the element

In a typical series, microgram amounts of silver (in rat brain) were estimated by assay of silver-110 (half-life 24 sec) Samples were irradiated for 24 sec, allowed to decay for 20 sec and counted for 30 sec to give a γ-ray spectrum, a further spectrum was recorded after the silver-110 activity had decayed to insignificance. The total computer time needed for each sample was 2 6 min and the cost of the analysis was 1 37 dollars At this price, activation analysis can compete with the more familiar methods used in hospital or agricultural laboratories

F Girardi and M Merlini (Euratom, Ispra) described a project for the estimation of trace elements in freshwater molluscs Up to 12 elements are separated chromatographically and examined by an automatic γ-ray spectrometer which supplies data on punched tape to an IBM computer for analysis and calculation

Papers on the uses of activation analysis in biological research could be classified into two groups The first was concerned with measurement of the concentration of particular elements in tissues or in the environment For some elements satisfactory techniques have now been devised, removing the uncertainties evident in earlier determinations Reported levels of manganese in tissue, estimated by activation analysis, have fallen steadily in recent years (as sources of contamination have been identified and eliminated), but now seem to have reached stability at well under 1 p p m

V P Guinn (General Dynamics Corporation, San Diego) presented relatively simple methods for the routine estimation of several elements in blood and tissue. W F. Bethard (San Diego) and Lars-Olof Plantin (King Gustav V Research Institute, Stockholm) discussed the correlation between levels of trace-elements in blood and various diseases, including leukæmia and rheumatoid arthritis

The difficult problem of estimating protein-bound stable iodine in human blood plasma (as a necessary supplement to turnover studies with radioactive tracers, such as iodine-131) has now been solved in a few laboratories. D Comar (Service Hospitalier Frédéric Joliot, Orsay) showed how activation analysis can be applied to routine determinations and to the study of abnormalities of iodine metabolism. The wider provision of such a service would fill an obvious and important clinical need

The relation of trace element metabolism to human disease was reviewed by J M A Lenihan (Western Regional Hospital Board, Glasgow), with particular reference to arsenic as a potential carcinogen Activation analysis is the only satisfactory method of measuring natural levels of arsenic in biological samples

R Soremark (University of Umeå, Sweden) reviewed the evidence for the protective action of vanadium against dental caries and described preliminary investigations by activation analysis The concentrations found in dentine and enamel from sound human adult teeth and in several foodstuffs were less than one part in 10^{11} Drinking-water levels were between one part in 10^9 and one part in 10^{10}, but parsley contained about one part in 10^6

A Fleckenstein described experiments on the study of intracellular metabolism of phosphoryl compounds The use of phosphorus-32-labelled phosphate as a tracer in this work has important limitations The radiophosphate does not readily pass through the muscle fibre membrane; if it does pass into the cell, the concentration of intracellular phosphate may increase to the point at which further access of the labelled tracer to the inside of the cell is blocked, creating the illusion of an inhibition of intracellular phosphorylation

Oxygen is a better tracer for the study of biochemical processes inside the cell Unfortunately, its radioactive isotopes have very short half-lives and are generally not very useful in such work The stable isotope oxygen-18, which forms 0 2 per cent of the natural element, can be incorporated in water at high concentrations (up to 80 per cent enrichment), but until recently could be assayed only by mass spectrometry Fleckenstein and his colleagues have used activation analysis based on the reaction ^{18}O(p, n)^{18}F, which offers a fast and sensitive method for measuring the rate of incorporation of oxygen from water into various phosphorus-containing compounds in cardiac and skeletal muscles

H Altmann (Reactor Centre, Siebersdorf, Austria) reported investigations using nucleic acids of tobacco mosaic virus to study the possible relation between trace-element levels and virus infection

R C Koch (Nuclear Science and Engineering Corporation, Pittsburgh) described work on the distribution of iodine-129, a nuclide which occurs naturally as a result of cosmic-ray reactions and spontaneous fission, but has recently been found in measurable quantities in debris from nuclear explosions The amount of iodine-129 in a typical human thyroid gland at the present time is about 10^{-11} g, and is far below the limit of chemical detection Activation analysis, using thermal neutrons to produce iodine-130 (half-life 12 5 h), enables reasonably accurate measurements to be made, as a basis for the assessment of long-term biological hazards and for studies of the movement of iodine in the biosphere

H J M Bowen (Wantage Research Laboratory, U K Atomic Energy Authority) emphasized the wide discrepancies among different laboratories in determinations of certain trace elements in biological material Experience in geochemistry and metallurgy has shown the value of standard samples, distributed for comparison of analytical results and techniques Bowen suggested that several biological materials, including algae, cabbage leaves, locusts, muscle, bone and blood, should be grown or collected under controlled conditions About 100 kg of each material would be required for use over a period of 10–15 years The samples should be dried, ground and distributed as required to laboratories working on activation analysis, so that they might compare their results on substantially identical specimens

The main conclusion which emerged from the Colloquium is that activation analysis, having passed through the stage of being an ingenious technique, now constitutes a powerful experimental weapon for biologists, biochemists and clinical research workers These beneficiaries have perhaps not appreciated fully the potentialities of new methods, but there is little doubt that the abounding enthusiasm of the effort now being applied to activation analysis will before long have a corresponding impact on biological science—including agriculture and veterinary medicine, which were not represented at all during this meeting

Some of the participants were unprepared for the 12-h working day prescribed by the organizers The ardours of this régime were handsomely mitigated by efficiency and hospitality, which culminated in a valedictory banquet at the château of Gif-Sur-Yvette under the genial chairmanship of Prof Francis Perrin, high commissioner for Atomic Energy.

J M A Lenihan

GAS CHROMATOGRAPHY

An informal symposium of the Gas Chromatography Discussion Group of the Institute of Petroleum was held at the Washington Singer Laboratories of the University of Exeter on September 27

The first paper was given by Dr I Halasz on "Gas-Solid and Gas Adsorption Layer Chromatography" He pointed out that gas-solid chromatography has now become an important subject for research again after having been displaced for a period by gas-liquid chromatography The disadvantages of gas-solid chromatography are (1) the upper limit of linearity of the isotherms of gas absorption is normally higher than it is for the solubility of gases in liquids, and (2) the number of available solids with suitable mechanical properties is strictly limited These disadvantages have now been largely overcome with the development of more sensitive detectors and new techniques Among the latter, Dr Halasz mentioned the modification of the highly polar known adsorbers by adding other solid substances, the coating of active solids with liquids for which Cremer has proposed the name 'gas adsorption layer chromatography', the coating of supports having a very large specific surface area with pulverized solids, and the coating of the inner wall of capillaries with a thin porous layer of solid In the latter case, the whole of organic and inorganic chemistry is available for experiment As regards the coating of an active solid with a liquid, preferably a polar one, some people assert that the active areas of the solid are blocked, and others suggest that the liquid changes its properties in the field of force of the solid, but Dr Halasz was of the opinion that a new stationary phase is formed, and he showed a graph in which an increase in the amount of liquid coating of alumina caused a decrease in retention volume of all C_1–C_4 components, a result in direct contrast to that obtained by gas-liquid chromatography

Two of the main advantages of gas-solid chromatography and gas adsorption layer chromatography are that mass transfer is much faster than in gas-liquid chromatography, and also that the vapour pressures of the stationary phases may be neglected or are, at the least, very low, a factor of special importance in programmed temperature operation Mass transfer will be especially fast in the case of a coating in the form of a thin porous layer, an advantage previously pointed out by both Golay and Purnell Five types of column were briefly defined as (*a*) classical packed columns in which the inner diameter of the column is larger than the particle size of the support by at least a factor of 10, (*b*) packed capillary columns having an inner diameter less than 1 mm, the particle size of the support being larger than one-fifth the inner diameter of the column, (*c*) classical open-tubes or capillaries (Golay columns) which have the inner surface coated with liquid, (*d*) porous layer capillary columns in which the inner surface is coated with a thin porous layer of active or inactive solid, (*e*) porous layer bead columns in which glass or metal beads are coated with a thin porous layer of solid support The performance of these types of column was illustrated by slides of work carried out by Heine and Horvath at Frankfurt C_1–C_4 hydrocarbons are separated fairly well on a packed capillary column of alumina in 13 sec, but although the resolution is a little better, separation took 360 sec on a classical packed column under the same conditions It has been found that hydrocarbons up to C_8 can be analysed on these packed capillary columns using alumina without much tailing of peaks but the column temperature must be relatively high (80° C) The same analysis can be carried out at 20° C by coating the alumina with 20 per cent by weight of β, β¹-oxydipropionitrile Many other similar illustrations were given, and in addition some separations using porous layer capillary columns of graphitized carbon black and silicon carbide, and porous layer glass bead columns using porous layers of zirconium oxide + triethylene glycol (for halogenated hydrocarbons) and ferric oxide + triethylene glycol (for aromatic hydrocarbons) In conclusion, Dr Halasz emphasized that his research programme was still in its early stages, and it was hoped that, in the future, better adsorbers would become available

A paper on "Modified Aluminas—A Progress Report" by C S G Phillips and C G Scott followed and was read by Mr Scott The selectivity obtainable with aluminas modified with either sodium hydroxide or a sodium halide was briefly reviewed, and it was shown that, apart from providing packings having a range of aromatic/alkene retention ratios, they could also be used to separate alkene *cis-trans* isomers. When aluminas are modified with cuprous chloride or silver nitrate, alkenes and aromatics can be held back completely, and the use of one of these packings as a subtractor was illustrated by two chromatograms of a Fischer–Tropsch Kogasin fraction. The first chromatogram, obtained on a sodium hydroxide modified alumina, gave all the alkane plus alkene peaks, and the second chromatogram, obtained on the same column to which a few millimetres' depth of cuprous chloride modified material had been added, gave the alkane peaks only. Apart from simple subtractor application in elution chromatography, the cuprous chloride and silver nitrate modified aluminas have been used to concentrate traces of alkenes and aromatics from large liquid volumes of alkane solvent. Recovery of the concentrates is achieved using gas-solid displacement chromatography. The main points to be observed with this procedure are (*a*) the displacer vapour should be more strongly adsorbed than the component to be displaced, and (*b*) the displacement fronts should be sharp—this requirement being met if the column packing is retained in the column by a flat sinter disk. When the total mass of concentrate is much less than 1 mg, it is found preferable to trap out the displacer front containing the displaced material and to re-inject it on to a gas-liquid elution column fitted with an ionization detector. The recovery of μg amounts of 1-hexene and 1- and 2-heptenes from 100 g of *n*-heptane using this procedure with 1-octene as displacer was described (see *Nature*, 199, 66, 1963). The same technique has been used successfully to recover traces of lower alcohols and ketones concentrated on sodium bromide modified material using *n*-butanol as displacer. With esters, hydrolysis occurs and the recovered material is a mixture of ester and alcohol.

Aldehydes polymerized on the column and traces cannot be recovered. The strong interaction between the adsorbates and the modified aluminas is such that appreciable amounts of adsorbate can be held on the surface with a negligible concentration in the gas phase. Thus as much as 20 mg of heptenes can be retained at 75° C on 1 g of alumina modified with silver nitrate. A column containing 50 g of packing can, therefore, hold 1 g of heptenes for displacement, and the technique can be used for preparing pure materials at this level of sample size. The specificity of the gas-solid elution columns for *cis-trans* isomers is found to be present in the strong interactions on the silver modified material, and a 1.5 ml charge of mixed 3-heptene isomers is separated into *cis*- and *trans*-fractions by displacement with 1-octene. In each case the fractions are recovered at better than 99 per cent purity. In order to obtain sharp displacement fronts, a sectional column is used having a 13 cm × 2 cm top section, a 10 cm × 1 cm centre section, and a 13 cm × 4 mm bottom section, in each of which the packing is retained by a sinter disk. High surface area solids such as carbon and silica-gel have also been used for preparative scale separations. The same apparatus holding 20 g of carbon is used to prepare ethyl propionate of better than 99.9 per cent purity. In the large-scale separation of ester mixtures and of hydrocarbon mixtures, it is found that at the change-over between pure components there is a high concentration of impurities together with a mixture of the two components flanking the change-over, and therefore the large-scale columns can be used either for the preparation of high-purity components or for the concentration of trace impurities.

"The Analysis of Surface Coating Resins by Pyrolysis-Gas Chromatography" was the subject of a paper read by Mrs. S. M. Rybicka, who emphasized the need for workers in such fields to be thoroughly conversant with the techniques of both pyrolysis and gas chromatography. She was of the opinion that many workers in the latter do not know enough about thermal pyrolysis to carry out investigations on polymers in an efficient manner, and this can easily lead to erroneous conclusions. Polymers can be divided into three main types, depending on the amount of hydrogen they contain: (*a*) those with a considerable amount, (*b*) those with a medium amount; (*c*) those with a small amount. These will give different products on pyrolysis. The thermal fission of polymers may also take place in three ways: (1) fission in the backbone of the chain which will give rise to free radicals which then become converted to stable compounds, (2) fission between the backbone and side groups, giving rise to double bonds in the chain, (3) highly cross-linked polymers, which give mainly carbonaceous material and a small amount of volatiles. The second method gives products which are ideally suited to analysis by gas chromatography, but analysis is more difficult in the third group. Pyrolysis may give some indication of the group to which a polymer belongs, but difficulties often arise when trying to discover what part the breakdown products play in the original polymer. The 'fingerprint' technique of German workers may lead to considerable errors if the full implications of the results are not properly understood. All results should be checked by infra-red spectroscopy, which in many cases will give all the information necessary without recourse to gas chromatography at all. The gas chromatographic technique should be properly used to give complete resolution of all the products obtained, and the pyrolysis should be carried out under carefully controlled conditions. The thermal stability of polymers may be investigated by pyrolysis at various temperatures. In summary, pyrolysis-gas chromatography can be a useful method of investigation, but it is best combined with infra-red spectroscopy or some other method in order to confirm the products obtained. Care must also be taken to ensure that, so far as possible, the products of reaction are stabilized before secondary reactions occur.

Dr. F. H. Pollard presented a paper on "Gas Chromatographic Studies of Compounds of Group IV A Elements", which detailed work carried out on the chromatography of organo-silicon, -germanium, -tin and -lead compounds. Most of the illustrative examples were from silicon chemistry, but many of the points made could have been quite easily taken from the chemistry of the tin compounds investigated. In the examination of such compounds, more specific problems occur than with the organic compounds of carbon itself, so that a general review of the factors likely to be involved is of interest. The injection of the sample may follow the standard procedure, but if it is readily hydrolysed, oxidized, or spontaneously inflammable, then special precautions must be taken. 'Celite' or 'Silocel' column supports often need acid-washing treatment, and complete removal of the acid is very important, especially in the analysis of chloro compounds. The stationary phase must obviously be inert to the compounds being analysed. In general, silicone oils or hydrocarbons like squalane or 'Apiezon' can be used. Other phases useful for specific purposes are: (*a*) dinonyl phthalate; (*b*) tritolyl phosphate, (*c*) 60 : 20 : 100 diethyl phthalate : silicone oil *E*301 : 'Celite', (*d*) silicone oil with a polypropylene glycol 400 plug, (*e*) 'Celite' having $n\text{C}_{16}\text{H}_{33}$-groups bonded directly to it, (*f*) nitronaphthalenes, which are particularly useful for lower chlorosilanes. As detectors, the katharometer, flame ionization gauge and gas density balance have proved to be the most useful. With the katharometer, there is a successive increase in molar response for the tetraalkyls of silicon, germanium, tin and lead, and also much less trouble than anticipated has been experienced owing to reactivity of compounds on the hot wire. The best design of flame-ionization gauge is one in which the plates are vertical. It has a high sensitivity and calls for very small samples, especially in cases such as tetramethyl tin, trimethyl ethyl silane, and similar germanium, tin and lead compounds, where a saturation effect begins at a very low level. This effect is thought to be due to actual ionization characteristics in the flame. The gas density balance has been found to be almost universal in its application since

PHYSICS [illegible]

the corrosive gases encountered so frequently in work of this type do not come into contact with the electrical parts It is found, however, that using such heavy molecular weight compounds of low boiling point, linearity is not observed except at very low concentrations—an effect illustrative of the kind of difficulty which may be encountered with work on unusual compounds The gas density balance has also been used for phosphorous chlorides, lower members of the phosphonitrilic chloride series and for a range of phosphonitrilic fluorides The problems met in the gas chromatography of organometallic compounds are well illustrated by the work described The compounds were chosen carefully so that they were amenable to study in this way, coupled with other physical methods such as infra-red spectroscopy Not only has gas-liquid chromatography enabled the analytical separation of materials to be carried out, but there have also been points of correlation between chromatographic behaviour and structure Dr Pollard emphasized the importance of gas-liquid chromatography in work of this kind, and advocated a bench-type chromatograph for every worker as standard equipment The application of gas-liquid chromatography to the groups investigated was well illustrated by slides In the case of the trimethyl silyl ethers, which hydrolyse easily and are thermally unstable on a katharometer wire, a maximum detector temperature of 150° C was used to preclude thermal breakdown, and the nitrogen carrier gas was carefully dried Although polyethylene glycol should be an ideal stationary phase for such a separation, the tendency to hydrolyse such compounds (which is virtually complete at 100° C) makes it necessary to use tritolyl phosphate or hydrocarbon phases which result in some loss of peak symmetry The methyl chlorosilanes have a narrow boiling range, and become far more liable to hydrolysis as chlorine replaces methyl The most satisfactory stationary phase is 60 20 100 diethyl phthalate silicone oil *E*301 'Celite' Preliminary pyrolysis and catalytic studies have been carried out on the methyl chlorosilanes and the trimethyl aryl silanes, and also work on rearrangement reactions involving interchange of alkyl groups using aluminium chloride as catalyst In the latter work, the number of alkyl groups used is such that it is possible to obtain 70 different products, many of which are isomeric and have closely similar boiling points Gas-liquid chromatography is virtually the only effective analytical method for such mixtures, and in order to identify individual components, most of the 70 possible compounds have been synthesized and their retention volumes determined Gas-liquid chromatography is also used for preparative work In conclusion, Dr Pollard paid tribute to similar work being carried out independently by the Oxford Group under Mr C S G. Phillips, and was able to report the good relationship and co-operation which exist between the two Groups

The last paper, on "Polymer Pyromania", by C E. Roland Jones and G E J Reynolds, was presented by Dr Reynolds He emphasized the widespread nature and application of polymers, and that pyrolysis combined with gas chromatography provided a useful method for analysis and investigation He distinguished between pyrolysis, by which he meant complete degradation to fragments, and stoving, which is a partial pyrolysis useful in thermal degradation investigations The advantages of the technique are its speed, simplicity and the use of small samples, but the interpretation of the results obtained is not always easy Very little work has been done in the quantitative field, and stringent conditions are necessary in order to obtain reproducibility of results. Four criteria are necessary to ensure this (*a*) pyrolysis must be rapid and complete, and optimum conditions must be secured in order to obtain this, (*b*) there should be a large heating area in relation to the sample, and the temperature rise should be as rapid as possible—the usual conditions used by Dr Reynolds were 700° C in 3 sec, (*c*) the possibility of gaseous diffusion must be kept to a minimum, (*d*) condensation of the products must be avoided Sample size is also very important and various workers have used samples varying from 10 mg to 20 μg, depending on the type of sample and ease of pyrolysis. It would seem that a thin film of sample is the most desirable form for rapid pyrolysis, although other forms have been used Gas chromatography for the identification of breakdown products should be supplemented by infra-red and ultra-violet analyses, and the products should be removed from the unit as quickly as possible to avoid secondary reactions taking place Slides of the pyrolysis unit and chromatograms of the breakdown products of various polymers were shown It was noted that the 'fingerprint' system mentioned by a previous speaker could, in some cases, be a useful means of identification

ADVANCES IN PROGRAMMING AND NON-NUMERICAL ANALYSIS

A FEW years ago a digital computer was regarded simply as a device which could do difficult sums very fast—given the good offices of someone versed in the black arts The magical intermediary, the programmer, translated one's problem at great length into a special form of gibberish, known as 'machine code' The final programme typically bristled with flights of hair-raising ingenuity, acquired in years of struggle with acute shortage of machine time and storage space

The situation is rapidly changing The advent, first of 'autocodes', and more recently of advanced programming languages, makes it increasingly possible for the user to describe his problem in terms which come naturally to the human mind and to leave it to the machine to translate his description into its own terms Secondly, the enormous increase in speed and storage of the new generation of machines largely liberates the user from cramping preoccupations with time and space Finally the joint impact of these two developments is not only enlarging the power and range of the discipline known as 'numerical analysis' —the art and science of doing difficult sums—but has also thrown open the new territory of non-numerical analysis Here the problems do not present themselves in primarily numerical form and demand an approach based mainly on logical rather than on numerical manipulations

One of the ways in which the University of Oxford Computing Laboratory, under the directorship of Dr L. Fox, has responded to these developments has been by organizing a summer school on the theme "Advances in Programming and Non-numerical analysis" The course, which occupied the two weeks August 26–September 6, consisted of a series of some thirty lectures contributed by a panel of ten speakers In the first lectures, the general theme of the course was outlined by Prof S Gill (Manchester College of Technology and Ferranti, Ltd) and the scope of the new non-numerical applications of computers was indicated Some of these belong to areas dominated by the immediate practical need for automatic aids, such as machine translation or medical diagnosis For others, such as the discovery of new mathematical proofs, immediate utility is negligible, but the long-term impact on human thought and life is impossible to calculate

Theorem-proving was taken by one of the speakers, D C Cooper (Bloomsbury Computers, Ltd), for detailed survey, ranging from 'heuristic' techniques as utilized by the Rand Corporation group[1] to Hao Wang's recent systematic assault on the predicate calculus[2] Other selected topics were algebraic manipulation (P M Woodward, Royal Radar Establishment, Malvern), game-playing and automatic learning processes (D. Michie, University of Edinburgh) and information retrieval, machine translation and the mechanical construction of time-tables (R M Needham, University of Cambridge)

Discussion of these applications, sampled from the rising flood of non-numerical analysis, sufficiently revealed the acute dependence of such work on development of more powerful programming languages It was natural, therefore, that the lectures on programming, delivered by C Strachey and D W Barron, formed the backbone of the course The ground was prepared by an introductory account by Dr Woodward of the nature of LISP[3], the prototype of the LISt-Processing facilities which are now seen as virtually mandatory features of a programming language if it is to lend itself to non-numerical work

The talks which followed conveyed a special atmosphere of immediacy in being based on the present effort, now in full swing in Cambridge and London, to construct a language which promises in all respects to be one of the world's most advanced, namely, CPL (Combined Programming Language)[4] It was an exciting experience to be taken behind the scenes and shown work in progress in what is in effect a new, and potentially major, branch of mathematics

The relation of computational processes to the abstract formulations of mathematical logic was expounded by P Landin[5], who has based his ideas on the λ-calculus of Church More practical problems of implementation were dealt with in lectures by J M Foster (Royal Radar Establishment, Malvern) and J K Iliffe (Ferranti, Ltd)

The digital computer is a device for handling information So long as its sphere of operation is restricted to the type of information which lends itself to direct numerical expression, the term 'electronic brain' will remain a misnomer But the increasing deployment into non-numerical applications is beginning to change the look of things Concern has even been expressed—and on Dr L Fox's initiative this became a subject of lively discussion at the summer school—at the social dislocations to be expected if not only manual labour but intellectual labour too is to be taken over by machines

If first workmen and craftsmen, then clerks, and ultimately business executives, military strategists, medical diagnosticians, school teachers, political and economic planners, lexicographers, linguists, and even perhaps mathematicians themselves are to be swept aside as outmoded instruments in successive waves of the industrial revolution, What part will remain for *Homo sapiens* ? In the controversy provoked by the question, only two points of unanimity could be discerned (1) that it was right that computer scientists should from time to time give some thought to the social impact of their brain-children, (2) that an all-out national effort is called for to expand and improve our educational system in an attempt to keep pace with the technological explosion

The lectures are being collected together with the intention of publishing them in book form The book will be edited by Dr Fox, who, together with his co-sponsors Prof Gill and Mr Strachey, planned this venture and piloted it to its successful conclusion D MICHIE

A ROCKET-BORNE LOW-FREQUENCY PROPAGATION EXPERIMENT TO DETERMINE *D*-REGION ELECTRON DENSITIES

By DR J. E. HALL

Radio Research Station, Department of Scientific and Industrial Research, Ditton Park, Slough, Bucks

AND

K. BULLOUGH

Department of Physics, University of Sheffield

THIS article presents the preliminary results of a rocket experiment designed to determine the height distribution of electrons in the *D*-region of the ionosphere Two *Skylark* rockets were successfully flown at Woomera, Australia (137° E , 31° S , magnetic dip 63°), at 1351 L M T on September 20, 1962, and at 0050 L M T on August 15, 1962 In this article the results of the day-time experiment are presented A continuous wave of frequency 202 kc/s was transmitted from the ground and, in the lower ionosphere, was subject to refraction, absorption, reflexion and changes in polarization The aim of the experiment was to send a rocket through the resulting wave pattern to measure the variations in field strength, and hence to deduce the ionospheric parameters

The transmitter delivered approximately 500 W to a horizontal half-wave dipole aerial supported 10 m above the ground but, owing to ground losses, the effective radiated power was only about 10 W The rocket was equipped with three mutually perpendicular receiving aerials which were carried, folded, inside the nose cone during the early part of the flight when aerodynamic forces were great At a height of 67 km the nose cone was discarded and the aerials deployed to form two dipoles of length 4 3 m perpendicular to the rocket's axis and a monopole which, together with the instrument section of the rocket, formed a longitudinal dipole of similar length These aerials were necessarily very short compared with the wave-length, and consequently had a large capacitive impedance which depended on the properties of the ionosphere To obtain an accurate measurement of the wave-field independent of the aerial impedance, it was necessary to use receivers with a very large input impedance

Three separate receivers were used, and, by means of telemetry, a record was made on the ground of the amplitudes of the received signals Fig 1 shows a section of the record obtained The orientation of the rocket was continuously changing during the flight and the corresponding changes in the E M F received on any one aerial obscured those caused by the amplitude variations of the wave-field for example, the deep minima in the records of Fig 1 were produced when the corresponding aerial was perpendicular to the electric field in the wave

When the preliminary analysis reported here was made, the attitude of the rocket throughout the flight was unknown, and a scalar field quantity $F = \sqrt{E_1^2 + E_2^2 + E_3^2}$, which was independent of the attitude, was formed from the E M F s E_1, E_2 and E_3 received on the three aerials This quantity F is plotted on a log scale in Fig 2 as a function of height From this curve it is noticeable that:

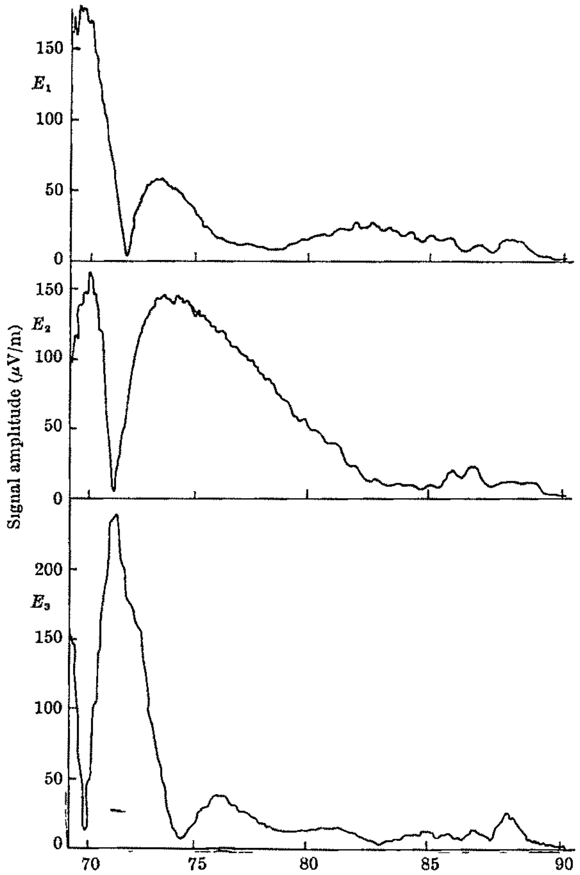

Fig 1 The height variation in the signal amplitude received on three orthogonal aerials

(*a*) ionospheric absorption causes the wave amplitude to decrease by a factor of ten between 70 and 80 km, (*b*) above 80 km the reflected wave was strong enough to produce a well-defined standing wave, (*c*) the wave-length of the standing wave increased with increasing height as the refractive index of the ionosphere decreased, (*d*) total reflexion occurred at a height of about 89 km

The results were interpreted in the following way A horizontally stratified model ionosphere was postulated in which both the electron concentration and collision frequency varied with height This was used to calculate the wave-field which would be set up in the ionosphere by a plane wave with the polarization of the transmitting aerial and incident along the line of sight from the transmitter to the rocket The calculation was made using the method described by Pitteway[1] and is based on a full-wave solution of the wave equation The model ionosphere was repeatedly adjusted until it yielded results closely resembling those deduced from the experiment

In practice it was often helpful to use the simpler ideas of magneto-ionic theory as a guide when fitting the measured field For example, as preliminary calculations had shown that the most important reflexion was near the level where $X = 1 + Y$ (the symbols have their usual meaning, see ref 2), it follows that the electron density at the reflexion height was about 4,300 cm^{-3} Furthermore, the roots of the Booker quartic could be used to calculate the spacing between the maxima and minima of the standing wave pattern and so give an approximate profile suitable for use in the initial full-wave calculation

The reflexion height and the spacing between maxima and minima depend on the real part of the refractive index which is fairly insensitive to the value of the collision frequency, but, to fit other features of the wave-field, it is necessary to know the effective collision frequency ν_{eff} as a function of height (ν_{eff} is the collision frequency appropriate to the Appleton–Hartree equation) To obtain this, the theoretical relationship $\nu_{\text{eff}} \propto \rho T$, where ρ and T are the density and temperature of the neutral air[3], has been used, and ρ and T have been taken from the 1961 *Cospar International Reference Atmosphere*[4] The constant of proportionality was obtained from the present observations as follows The depth of modulation in the standing wave pattern near the reflexion-level depends on both the collision frequency and the gradient of electron density As the latter had been determined from the spacing of the pattern, the collision frequency which produced the correct modulation depth was easily found after a few trials of the full-wave programme Molmud[3] also shows that the ratio between ν_{eff} and the simple kinetic theory value, ν, depends on whether ν is greater or less than the angular wave frequency As these become equal within the height interval of interest, ν_{eff} has been allowed to vary smoothly from one limiting value to the other between 75 and 95 km The height-distribution of

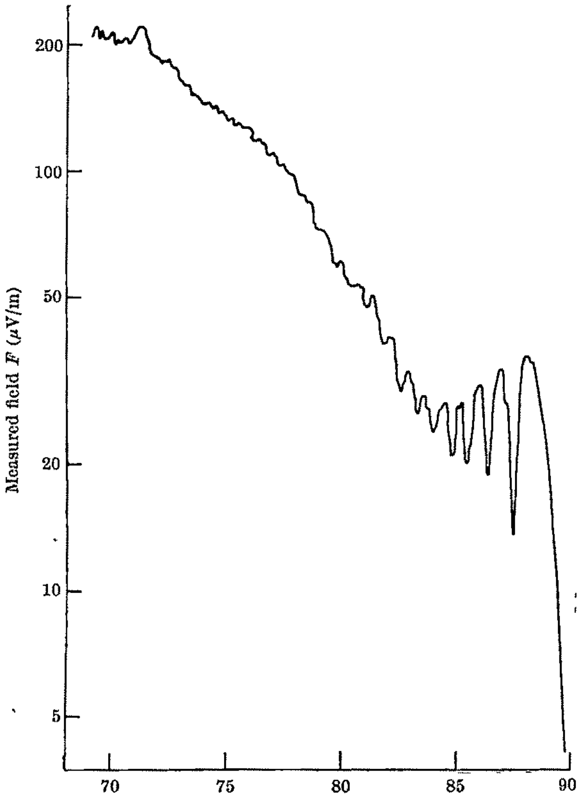

Fig 2 Observed scalar field $F = \sqrt{E_1^2 + E_2^2 + E_3^2}$ versus height

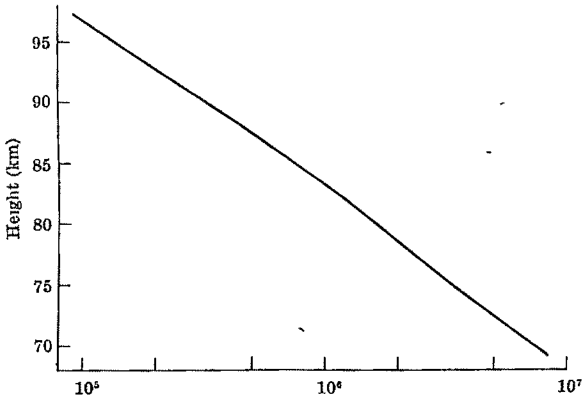

Fig 3 The height variation in the effective collision frequency, ν_{eff}, at 202 kc/s

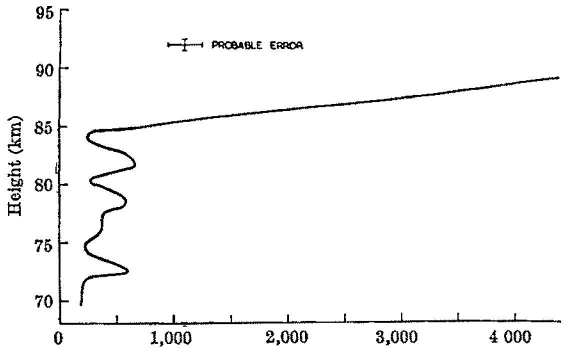

Fig. 4. Height variation of electron density deduced from the rocket experiment

the effective collision frequency at 202 kc/s which has been used in these calculations is given in Fig. 3.

The most successful electron density model is shown in Fig. 4 and the theoretical variation of the scalar field *F*, calculated using this model, is given by the continuous line in Fig. 5. This can be compared with the observed variation indicated by the dotted line. An interesting feature of the height-distribution is the contrast between the steep gradient of electron density above 84 km and the smaller variations below. We cannot attach too great a significance to the small fluctuations in electron density below 84 km since the estimated error in the density (± 150 cm^{-3}) is of similar magnitude. However, the experimental results correspond more closely to the wave-field calculated using the curve of Fig. 4 rather than to the wave-field calculated from a smooth curve which ignores the fluctuations.

A more detailed analysis of the results will be possible when information is available about the attitude of the rocket and, in particular, a knowledge of the polarization changes occurring below 80 km should lead to a more accurate estimate of the electron concentration at those heights.

A rocket experiment such as this involves too many personnel to mention individually, but we thank those, in Britain and in Australia, who have been concerned with the preparation of the equipment, the launching of the rocket and the reduction of the data.

OXYGEN ISOTOPIC FRACTIONATION IN THE WATER OF CRYSTALLIZATION OF GYPSUM

By DR. R. GONFIANTINI and J. C. FONTES*
Laboratorio di Geologia Nucleare del C.N.E.N., Pisa

THE isotopic composition of the water of crystallization of gypsum samples can provide information of geochemical and geological interest. For the correct understanding of such isotopic data, it is necessary to know the fractionation factor between the water of crystallization of the gypsum and the water in which the gypsum is deposited. Here, we give some results on the experimental determination of this fractionation factor. At present they are limited to $^{18}O/^{16}O$ measurements, but this research will be extended to D/H measurements.

The oxygen isotopic composition of water samples was determined by equilibrating them with carbon dioxide at 25° C, and then analysing the carbon dioxide with a mass spectrometer Atlas *M*86. The isotopic results are expressed in terms of difference in parts per mil ($\delta^{18}O$) of the $^{18}O/^{16}O$ ratio in the sample and in the 'standard mean ocean water' as defined by Craig[1]. The standard error of the isotopic measurements of water is ±0·1 $\delta^{18}O$ units for samples not too different from the working standard, as in this case.

The water of crystallization was extracted by slowly heating the gypsum sample (20–30 g) under vacuum to 400° C in a 'Pyrex' vessel, and water was trapped at liquid nitrogen temperature. Usually, with commercial pure crystalline calcium sulphate or with optically pure natural gypsum, yields of 100 per cent were obtained. With other natural samples, yields were usually lower, depending on the amount of impurities.

The reproducibility of the isotopic measurements of water of crystallization has been tested using a commercial pure crystalline calcium sulphate (product of C. Erba RP) and on optically pure natural gypsum. Four samples of the former gave respectively the following results (in $\delta^{18}O$): $-4·4$, $-4·5$, $-4·6$, $-4·6$ (average $-4·5$). Ten samples of the latter gave the following results (in $\delta^{18}O$): −3.6, −3.6, −3.8, −3.9, −3.9, −4.0, −4.1, −4.1, −4.2, −4.2 (average −3.9) respectively. On the basis of these results, we assume that the isotopic measurements of water of crystallization are affected by an error of ±0.3 $\delta^{18}O$ units.

---

* Present address: Laboratoire de Géographie Physique et de Géologie Dynamique à la Sorbonne, Paris.

Isotopic exchange between oxygen of the sulphate and oxygen of the water of crystallization can be excluded during the extraction process. In order to prove this, two different tests were made.

In the first, anhydrous calcium sulphate was mixed with water of known isotopic composition in the same proportion with regard to the sulphate as in the gypsum. Afterwards, water was extracted in the method described here, as from a gypsum sample. This water preserved its original isotopic composition, not showing any appreciable exchange with the oxygen of the sulphate.

In the second test 71 g of anhydrous calcium sulphate were converted into gypsum at room temperature with 100 ml. of solution of 0.5 M sodium sulphate, following the method of Conley and Bundy[2]. The results of the isotopic analyses were (in $\delta^{18}O$): water before gypsification (100 ml.), −7.1, water after gypsification (81.2 ml.), −8.3, water of crystallization (18.8 ml.), −1.8. The isotopic balance existing between the first and the last two waters excludes any exchange with the oxygen of the calcium sulphate[3].

For the determination of the isotopic fractionation factor between water of crystallization of gypsum and water in which the deposition occurs, two sets of experiments were carried out.

(1) The aim was to obtain gypsum by evaporation of an aqueous solution of calcium sulphate keeping the isotopic composition of the water constant during deposition.

From the reservoir 1 (Fig. 1) distilled water was admitted in the container 4 through the flask 2, on the top of which the overflow 3 was fixed. The water in 4, stirred by the magnetic stirrer 5, was evaporated using the infra-red lamp 6, the level of the water being kept constant by means of the overflow. During the process, the temperature was periodically checked and it was found to be constant to about ± 1° C.

After about 100 h, the isotopic composition of the water in 4 attained a constant value (Fig. 2). When this isotopic steady state was reached, a solution of calcium sulphate (obtained by dehydration of pure gypsum) was introduced into 1 and after some hours gypsum began to crystallize in 4. During crystallization, the water in 4 showed a fairly constant isotopic composition (Fig. 2).

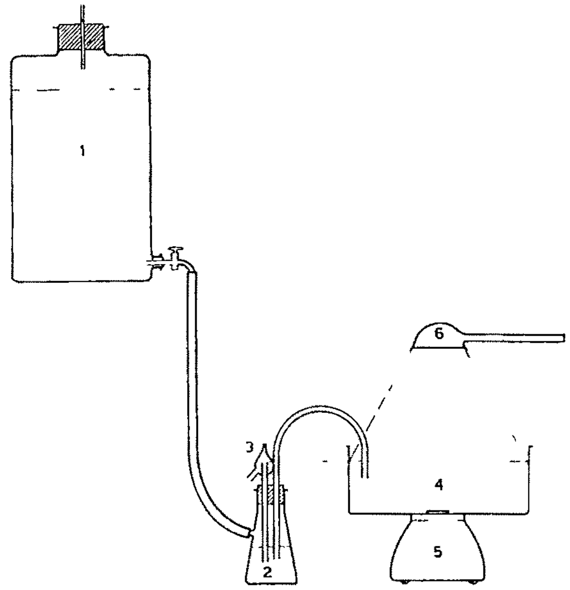

Fig. 1. Apparatus for preparing gypsum by evaporation of a calcium sulphate solution with constant isotopic composition. 1, reservoir, 2, flask with overflow 3, 4, container, 5, magnetic stirrer, 6, infra-red lamp

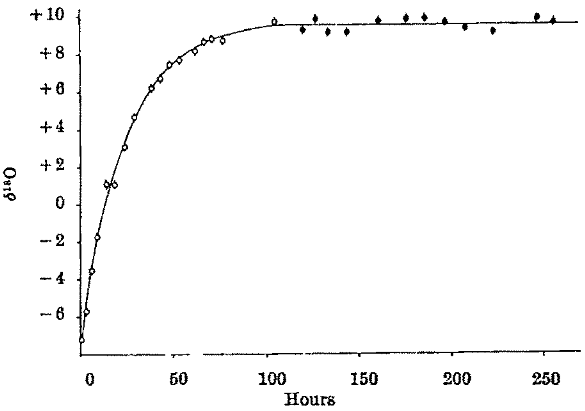

Fig. 2. Isotopic composition of water in the container 4 during the experiment illustrated in Fig. 1. Open circles, before the beginning of the crystallization of the gypsum, filled circles, during the crystallization of the gypsum

When a sufficient amount of gypsum was obtained, it was filtered and dried, and its water of crystallization was extracted and analysed for its $^{18}O/^{16}O$ ratio. Isotopic results of two experiments at 57° and 47° C are given in Table 1.

Table 1. OXYGEN FRACTIONATION FACTOR BETWEEN WATER OF CRYSTALLIZATION OF GYPSUM AND MOTHER-WATER

Temperature °C	Method	Oxygen isotopic composition ($\delta^{18}O$) Water of crystallization	 Mother-water	α
57	i	+12.7	+9.5	1.0032 ± 0.0006
47	i	+14.2	+11.3	1.0029 ± 0.0006
37	ii	−3.3	−7.2	1.0039 ± 0.0004
25	ii	−3.3	−7.4	1.0041 ± 0.0004
20	ii	−3.2	−7.2	1.0040 ± 0.0004
17	ii	−3.3	−7.2	1.0039 ± 0.0004

i, Method by evaporation in isotopic steady state, ii, method of gypsification (ref. 2).

Error for experiments following the method (i) is higher, due to the fluctuations of the isotopic composition of the evaporating water.

(2) For lower temperatures the preceding technique would require too much time because of the low evaporation rate. For this reason, we followed the method of gypsification proposed by Conley and Bundy[2].

About 30 g of anhydrous calcium sulphate were converted to gypsum by stirring with about 1,000 ml. of solution of 0.5 M sodium sulphate in a closed vessel (to prevent evaporation). As catalyst of gypsification, sodium sulphate was preferred to potassium sulphate because in the hydration sphere of Na^+ no isotopic fractionation occurs in relation to the solvent[4], so that no disturbances in isotopic composition of the solvent are expected.

The temperature was kept constant by a thermostatic bath. After 24 h the conversion was complete, the gypsum was filtered and dried, and its water of crystallization was extracted and analysed. Experiments have been made at 37°, 25°, 20° and 17° C, and the isotopic results are given in Table 1.

In both methods, the purity of the gypsum was checked by X-ray diffractometry, practically 100 per cent purity of gypsum was obtained.

The fractionation factor α is defined as

$$\alpha = \frac{(^{18}O/^{16}O)_{cw}}{(^{18}O/^{16}O)_{mw}} = \frac{1000 + \delta^{18}O_{cw}}{1000 + \delta^{18}O_{mw}}$$

(*cw*, water of crystallization, *mw*, mother-water).

The two methods of preparation of gypsum give slightly different values of α: in the first one we found 1.003, while in the second one 1.004. Taking the errors into account, we cannot determine with any degree of certainty whether the foregoing difference can be attributed to a temperature effect on the α-value in the temperature range in which the experiments have been carried out; however, this effect would be little and, in any event, would be contained in the experimental error

Our results show that the water of crystallization of gypsum is enriched in heavy isotopes in relation to the water in which gypsum was deposited This can be explained admitting that the crystallization water of gypsum is related to the water of the hydration sphere of Ca^{++}, which is presumably enriched in heavy oxygen isotope in relation to the solvent, because of the difference in vibration frequencies of the two isotopic forms of water along the bonds formed between water and cation[4]

The α-value found by us is in good agreement with that reported by Baertschi[5], who found $\alpha = 1\ 0035$, but disagrees with the data reported by Teis[6], who found that water of crystallization was depleted in heavy oxygen content in gypsum samples obtained chemically from solutions of calcium chloride and sodium sulphate This method did not give us reproducible results, and it was abandoned. Nevertheless, we should like to point out that in seven experiments of this kind, we found α-values of 1 0069–1 0029, always showing an enrichment in oxygen-18 in the water of crystallization

Assuming, on the basis of results reported in Table 1, that α is constant in the range of temperatures in which gypsum deposition occurs in Nature, it becomes possible to deduce from isotopic analyses of the water of crystallization the isotopic composition of the water in which gypsum has been deposited This can provide some important data on the environmental conditions of deposition in fact, the isotopic composition allows one to distinguish fresh waters from marine ones and to obtain information on the evaporation

Two facts have to be taken into account

(1) Gypsum could have been dehydrated and rehydrated during its geological history in such a case we are only dealing with the rehydration water which will probably be a meteoric one

(2) Isotopic exchange can occur with meteoric water percolating in the gypsum deposit Information about the kinetics of this exchange reaction is reported by Teis[6]

These difficulties can be overcome in some cases by a comparative examination of the isotopic composition of the gypsum water of crystallization and of the limestone associated with gypsum deposits, and utilizing all the available geological data From a study of this kind on the well-known gypsum of Paris, the origin of which was still under discussion, it was found that the fossil basin where deposition occurred was supplied by fresh water[7]

This work was carried out under contract with EURATOM —U L B—C N E N, No 013-61-7 *AGEC*

[2] Conley, R F , and Bundy, W M , *Geochim et Cosmochim Acta*, 15, 57 (1958)

[3] In this experiment the observed value of the fractionation factor was 1 0065, higher than in the other cases reported in Table 1, this could be due to the small amount of water in proportion to the calcium sulphate and to the bad stirring of the resulting mixture This could perhaps be responsible for the fact that isotopic equilibrium between gypsum and the mother-water was not completely attained

FRACTURE OF LIQUIDS IN SHEAR

By J F HUTTON
"Shell" Research, Ltd , Thornton Research Centre, P O Box 1, Chester

SOLIDS fracture in both tension and shear, and it is generally accepted that liquids fracture in tension (an effect referred to as cavitation) but not in shear For some years it has been recognized that an instability occurs during the flow of non-Newtonian visco-elastic materials, for example, in the flow of molten high molecular weight polymers through tubes[1] and in cone-and-plate viscometers[2], and in the flow of soft bitumens[3] and silicone fluids[4] in cone-and-plate viscometers The purpose of this article is to present experimental results which, when interpreted in conjunction with a simple theory, demonstrate that liquids can fracture in shear The experiments were carried out on silicone fluids in two types of cone-and-plate viscometer

Fig 1 shows a typical set of results obtained with the Ferranti–Shirley cone-and-plate viscometer[5] The material is *MS* 200/30,000 silicone fluid (a polydimethylsiloxane manufactured by Midland Silicones) which has a viscosity at 30 0° C of 288 poise at low rates of shear In an experiment the rate of shear was maintained constant and the shear stress was determined as a function of time Experiments were carried out using the different values of rate of shear shown on the right of the diagram It is seen from the figure, ignoring for the moment the dotted curves, that as the rate of shear increases from the lowest value of 184 sec^{-1} the shear stress increases The stress increases less than proportionately to the shear rate, showing that the silicone is non-Newtonian At rates of shear below 900 sec^{-1} the stress is stable for at least 5 min shearing, but over the relatively narrow range of 900–1,000 sec^{-1} there is a marked transition from stable to unstable flow The instability is revealed as a fall in shear stress the higher the rate of shear the shorter the time lapse before the fall occurs and, possibly, as indicated by other experiments, the greater the fall When the shear stress nears equilibrium it oscillates considerably The vertical lines on the curves indicate the extent of the oscillation

Explanations of the fall in shear stress are usually in terms of thixotropy or of structural breakdown[2,3], with the implication that the extent of breakdown is uniform throughout the sample The results to be presented here show that uniform breakdown is unlikely The breakdown is believed to be localized on a conical fracture surface which starts at the periphery of the sample and grows radially inwards The shear stress falls because the effective shearing radius decreases as the fracture grows

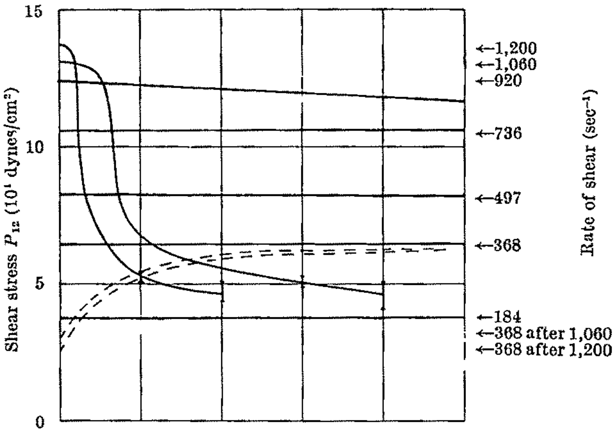

Fig 1 Shear stress as a function of time, illustrating the onset of flow instability and the recovery during stable flow after a period of unstable flow Ferranti–Shirley viscometer, 1/3° angle, 1 cm radius cone, 30 0° C, *MS* 200/30,000 silicone

Since the silicone fluid is a liquid, the fracture would be expected to heal at stresses below the transition. The dotted curves in Fig. 1 show the manner in which the stress increases after the rate of shear has been rapidly reduced from 1,060 sec^{-1} and 1,200 sec^{-1} to 368 sec^{-1}. The stress in each case recovers completely to the normal equilibrium value corresponding to the rate of shear of 368 sec^{-1}. Molten polyethylene also shows such a stress recovery[2].

At still higher rates of shear the sample aerates and is thrown out of the shearing zone. In this event recovery is not observed.

Near the point of instability the Weissenberg effect is quite pronounced, the excess liquid around the viscometer cone climbing a little way up the outside of the rotating cone. In addition, the normally curved meniscus of the excess liquid divides into two, one enclosing a collar of liquid on the cone and the other enclosing a bank of liquid on the stationary plate. This division suggests fracture. With large diameter (7·5 cm), large-angled cones (1° angle between the cone surface and the surface of the flat plate) the gap between the shearing surfaces at the periphery of the cone is large enough to permit the observation of a division of the liquid inside the main shearing zone.

The temperature rise of the liquid measured at the surface of the stationary plate is negligibly small, thus indicating that the observed fall of stress is not due to heating effects. Tests with the near-Newtonian liquid treacle, having a viscosity of about 150 poise at 30° C, also prove that viscous heating plays no part. Treacle shows no fall of stress at power dissipations of up to three times that at which a silicone of similar viscosity fractures.

Nor is the effect due to turbulence. Low viscosity Newtonian mineral oils can be tested in the cone-and-plate viscometer without turbulence at Reynolds numbers many orders higher than the Reynolds numbers at which the silicone fluids fracture.

Rather, the effect appears to be one of fracture, and the observation of a Weissenberg effect indicates that it is linked with the elasticity of the liquid. The following theory is based on these conclusions.

An elastic solid in a state of strain possesses elastic energy which is released when the solid is allowed to recover. Similarly a visco-elastic liquid in a state of flow possesses elastic energy, and when the shear is stopped, the liquid recoils because of the release of this energy. It is postulated that when the total elastic energy contained in the sheared sample of liquid exceeds a critical value the liquid will fracture, and that the fracture surface in a cone-and-plate viscometer is a cone with apex coincident with that of the viscometer cone. It is further postulated that fracture will occur only when the total elastic energy is at least sufficient to supply the energy requirement of the new surface formed. Therefore fracture will occur when

$$fGS_e^2V/2 \geqslant 2\pi R^2\gamma \qquad (1)$$

where G is the shear modulus, S_e, the recoverable elastic shear strain and γ, the surface tension of the liquid, V is the volume of the sample, determined by the cone radius, R, and angle φ, f is a fraction representing the part of the elastic energy which is converted to surface energy. For the uniform laminar shearing motion obtaining in a cone-and-plate viscometer there is a choice of expressions for G and S_e. Jobling and Roberts[6] quote Weissenberg's theoretical results as follows

$$G = P_{12}^2/(P_{11} - P_{22}) \qquad (2)$$

and

$$S_e = (P_{11} - P_{22})/P_{12} \qquad (3)$$

where $(P_{11} - P_{22})$ is the normal stress difference and P_{12} is the shear stress acting in the liquid. Both are measurable.

However, Lodge[7], on the basis of his network theory, calculates the values

$$G = 2P_{12}^2/(P_{11} - P_{22}) \qquad (4)$$

and

$$S_e = (P_{11} - P_{22})/2P_{12} \qquad (5)$$

Substitution into equation (1) leads to the result that fracture will occur when

$$(P_{11} - P_{22}) \geqslant n\gamma/R\varphi \qquad (6)$$

where n is $6/f$ or $12/f$ depending on whether the Weissenberg or the Lodge theory is used.

For a liquid in Newtonian flow the elastic energy is zero $(P_{11} - P_{22})$ is zero and fracture in shear does not occur. For a liquid that behaves visco-elastically $(P_{11} - P_{22})$ increases with rate of shear and fracture will begin to be observed at the critical value given by

$$(P_{11} - P_{22})_c = n\gamma/R\varphi \qquad (6a)$$

The shearing must be allowed to continue sufficiently long for the equilibrium theory to apply.

Preliminary results have been obtained to prove the validity of the theory. For polydimethylsiloxanes of 1 poise viscosity and greater, γ is practically independent of molecular weight and lies between 21 and 22 dynes/cm (say, 21·5 dynes/cm) (ref. 8). The equation (6a), therefore, predicts that all higher molecular weight polydimethylsiloxanes will fracture at the same critical normal stress difference. It also predicts a linear relationship between $(P_{11} - P_{22})_c$ and $1/R\varphi$. The results given in Table 1 were obtained with the Ferranti–Shirley cone-and-plate viscometer on which only the shear stress P_{12}, but not the normal stresses, can be measured. Results are given for the smallest shear stresses at which fracture was observed in a 5-min shearing period. In making the measurements care was taken to remove excess liquid round the cone. The effect of excess liquid was to increase the critical fracture stress to an extent that increased with decrease in cone radius. On the other hand, the amounts of excess liquid involved had no influence on the shear stresses. The curves in Fig. 1 were obtained with a small excess of test liquid, and they indicate a critical fracture stress of about 12 × 10^4 dynes/cm^2, whereas the correct value (Table 1) is 8·0 × 10^4 dynes/cm^2. Results are estimated to be accurate within about 10 per cent. The low values for *MS* 200/100,000 are significantly different from the values obtained for the other three fluids. According to measurements made by Benbow and Howells[9] the values of $(P_{11} - P_{22})$ corresponding to shear stresses in the range 5·0–6·0 × 10^4 dynes/cm^2 lie between 3·5 and 5·0 × 10^4 dynes/cm^2. This correspondence, to a first approximation, is not dependent on molecular weight or temperature. Similarly, the shear-stress range 7·0–8·5 × 10^4 dynes/cm^2 corresponds to a normal stress range of about the same values, say, 7·0–8·5 × 10^4 dynes/cm^2.

Hence the predictions that the critical normal stress difference is independent of molecular weight but dependent on $R\varphi$ are supported.

Normal stresses have been measured on the 2,000-poise silicone in the Weissenberg rheogoniometer[3,6]. The

Table 1. SHEAR STRESSES AT THE ONSET OF FRACTURE FOR SILICONE FLUIDS IN THE FERRANTI–SHIRLEY VISCOMETER (TEMP. 30·0° C)

Silicone fluid		Shear stress at fracture (10^4 dynes/cm^2)	
Designation	Zero shear viscosity (poises)	Medium cone } R=2·0 cm, φ=0·00603 rad	Small cone } R=1·0 cm, φ=0·00606 rad
MS 200/12,500	108·5	5·5	8·5
MS 200/30,000	288	5·5	8·0
MS 200/100,000	944	5·0	7·0
MS 200/200,000	about 2,000	6·0	8·5

rate of shear is adjustable in increments of about 25 per cent on this instrument, so the onset of fracture cannot be exactly pinpointed In the results given in Table 2 the observed limits of normal stress difference correspond to rates of shear at which fracture was and was not observed after 5-min shearing. No detailed assessment has been made of the accuracy of these results

Table 2 NORMAL STRESS DIFFERENCES AT THE ONSET OF FRACTURE OF *MS* 200/200,000 SILICONE FLUID IN THE WEISSENBERG RHEOGONIOMETER (TEMP , 20° C)

R cm	φ rad	Normal stress difference (10^4 dynes/cm^2)
1 25	0 018	2 5 3 5
3 65	0 033	0 40 0 55

To find the dependence on $R\varphi$, values of $(P_{11} - P_{22})_c$ are plotted against $1/R\varphi$ in Fig 2 This figure includes the results in Table 2 and those in Table 1 converted by means of Benbow and Howells's results, the validity of the conversion being supported by our own results on the 2,000-poise fluid

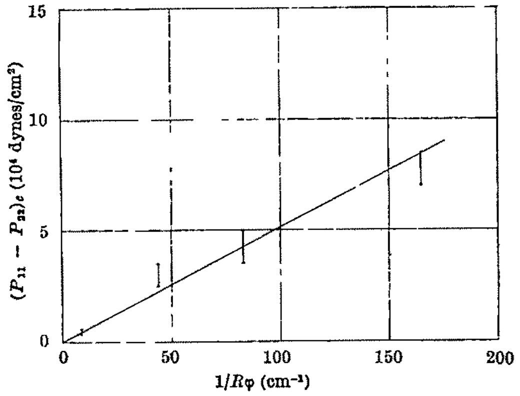

Fig 2 Variation of critical normal stress difference at fracture with the product of cone radius and angle for silicone fluids in cone-and-plate viscometers

The linear relationship predicted by equation (6*a*) is seen to hold reasonably well over a 20-fold range of values of $R\varphi$ From the slope and surface tension, n is found to be about 24 Therefore it follows that fracture will occur when the elastic energy possessed by the liquid is about four times, by Weissenberg's theory, or twice, by Lodge's theory, the free energy needed for forming the new air/liquid interface

Thus, the concept of a limit of elastic shear energy for a liquid has led to a theory that predicts the conditions for the onset of flow instability of silicone fluids in cone-and-plate viscometers The equations developed contain uncertain terms Thus, there is uncertainty about the choice of theory to calculate the elastic shear energy, the choices available leading to a difference of a factor of two There is uncertainty also about the fraction of elastic energy available for forming the fracture surfaces However, by combining these uncertainties into one adjustable dimensionless number, an equation is obtained which, after calibration to determine the number, can be used to predict quantitatively the fracture conditions

A practical use for the theory in the laboratory lies in the selection of a viscometer cone that will permit the measurement of viscosity over the widest possible range of shear rate In choosing a cone a compromise must be reached between a low value of $R\varphi$ to avoid flow instability and a high value of $R\varphi$ to achieve accuracy of measurement It is expected that the fracture phenomenon will be important in a number of other applications of fundamental and technological importance, but its occurrence will depend on the geometry of the device in which the liquid is sheared

NATURE OF THIN OXIDE FILMS ON METALS AS REVEALED BY WORK FUNCTION MEASUREMENTS

By C. M. QUINN and DR M W. ROBERTS
Department of Chemistry, The Queen's University of Belfast

THE outstanding feature of the results so far obtained for the changes in work function ($\Delta\varphi$) resulting from the interaction of oxygen with metal surfaces is the great variation that exists for any given metal This is particularly true for oxygen on nickel, and Table 1 summarizes the values of $\Delta\varphi$ reported by different investigators at various temperatures

Table 1 SUMMARY OF $\Delta\varphi$ VALUES FOR OXYGEN ON NICKEL OBSERVED BY VARIOUS INVESTIGATORS

$\Delta\varphi$ (V)	Temperature (°C)	Technique	Ref
−1 6	−195	capacitor	1, 2
−0 55	25	photoelectric	3
−1 4	25	diode	4
~ −0 7	25	capacitor	5
−0 55	25	capacitor	6

We have investigated changes in work function during the interaction of oxygen with a number of metal films which have been prepared under high vacuum conditions (10^{-7}–10^{-8} mm) The general procedure was to admit a small dose of oxygen and to measure the associated change in work function, doses were added until the pressure was about 10^{-2} mm and $\Delta\varphi$ constant[5] In some experiments the influence of suddenly increasing the pressure from 10^{-2} mm to about 50 mm with the film at 20° C was also investigated Measurements were made by a capacitor technique and it is assumed that the work function of the gold reference electrode did not vary during an experiment

Changes in work function have been measured with three different metal film surfaces (nickel, iron and molybdenum) between −195° and 25° and up to an oxygen pressure of 50 mm In the case of nickel, only at −195° was $\Delta\varphi$ reproducible to better than 50 mV, at an oxygen pressure of 10^{-4} mm $\Delta\varphi$ was −1 45 V and became slightly more positive (−1 25 V) at 10^{-2} mm This positive contribution to $\Delta\varphi$ of about +0 2 V could be easily reversed on evacuating the cell to 10^{-6} mm Table 2 summarizes the data obtained with nickel under various conditions, clearly $\Delta\varphi$ is very sensitive to the oxygen pressure and temperature A negative value of $\Delta\varphi$ implies an increase in the value of the work function of the clean metal

In the case of iron films, $\Delta\varphi$ was reasonably insensitive to the oxygen pressure and to temperature The value of

Table 2 CHANGES IN THE WORK FUNCTION OF NICKEL FILMS UNDER DIFFERENT CONDITIONS OF OXYGEN INTERACTION

$\Delta\varphi_1$	$\Delta\varphi_2$	$\Delta\varphi_3$	$\Delta\varphi_4$
−1 45	−0 7 to −0 8	−0 9 to −1 0	−1 2

$\Delta\varphi_1$ refers to dose-wise interaction at −195°, $\Delta\varphi_2$ dose-wise interaction at 25°, $\Delta\varphi_3$ interaction at 25° after initially adsorbing oxygen at −195°, and $\Delta\varphi_4$ the addition of 50 mm of oxygen at 25°

$\Delta\varphi$ was −1 6 V at 10^{-2} mm and −195°, was virtually the same at 10^{-2} mm and 25° and did not change when the pressure was increased to 50 mm Molybdenum films showed similar insensitivity to ambient conditions and $\Delta\varphi$ was −1 8 V

With iron we know that oxygen incorporation into the lattice (oxidation) is extensive at low temperatures and pressures[7], incorporation is also thought to occur with nickel at 25° and an oxygen pressure of 10^{-2} mm (ref 8) In the case of molybdenum a stable chemisorbed layer is virtually complete at 10^{-2} mm and 25° and from which incorporation is unlikely $\Delta\varphi$ with molybdenum, therefore, refers to a chemisorbed layer only It is, therefore, necessary to rationalize why with iron $\Delta\varphi$ is insensitive to oxygen pressure but with nickel the reverse is true, yet both incorporate oxygen at 25°

The rate at which iron films oxidize is rather insensitive to changes in oxygen pressure[7] at 25° Thus, variation in oxygen pressure will make little difference to the oxide already formed on the iron surface and, therefore, will have a negligible effect on the work function of the oxide

Nickel oxide is a *p*-type semiconductor in the bulk form and the conditions at the oxide–gas interface are extremely important in oxide growth The rate of formation of such *p*-type oxides is known to be very sensitive to pressure (for example, Cu_2O where the pressure dependence of the rate is about unity[9]) and the formation of cation vacancies with associated positive holes is known to play an important part in oxide growth (equation (1))

$$2e + \tfrac{1}{2}O_2(\text{gas}) \rightarrow O^{2-}(\text{ads}) \rightarrow Ni^{2+}O^{2-} + \square\ (Ni^{2+}) \qquad (1)$$

where $\square\ (Ni^{2+})$ is a cation vacancy which will have associated with it a positive hole

Consequently, if by changing the oxygen pressure we effect extensive oxide growth and the new oxide has a different stoichiometry to that already existing on the surface we might expect a change in $\Delta\varphi$ The $\Delta\varphi$ of −1 45 V for oxygen on nickel at −195° is, therefore, considered to reflect the influence of chemisorbed oxygen on the work function of the metal The positive effect of +0 2 V is due to adsorbed molecular oxygen At 25° a semiconducting oxide is formed, and the extent to which oxidation occurs, and more particularly the density of acceptor states associated with excess oxygen, determines the observed value of $\Delta\varphi$ Clearly this is a kinetic phenomenon, and the extent to which the defects (and consequently acceptor states) are formed or annihilated will determine the change in work function observed We, therefore, find extensive variability of $\Delta\varphi$ even at 25° and 10^{-2} mm, $\Delta\varphi$ tending to be more negative if the chemisorbed layer has been first formed at −195° and then warmed to 25° than if interaction had only occurred at 25° Also $\Delta\varphi$ is very sensitive to the oxygen pressure at 25°

The results presented here, therefore, show a close relationship between the electrical properties of an oxide and possible non-stoichiometry Moreover, the apparent inconsistencies observed for $\Delta\varphi$ in the nickel–oxygen system (Table 1) can be rationalized in terms of our results and concepts

DETERMINING THE CO-ORDINATION NUMBER OF ALUMINIUM IONS BY X-RAY EMISSION SPECTROSCOPY

By DELBERT E. DAY
Concrete Division, Waterways Experiment Station, Jackson, Mississippi

THE wave-length of the characteristic X-radiation emitted by certain elements depends to some extent on the valence state of the element[1]. For certain elements of low atomic number, the wave-length of the characteristic X-radiation is also influenced by the co-ordination number (number of nearest neighbours) of the site occupied by the element White, McKinstry and Bates[2] reported a small difference in the wave-length of aluminium *K*α-radiation when the aluminium ions occupied four-fold and six-fold co-ordination sites This difference in wave-length was used by Brindley and McKinstry[3] and by Day and Rindone[4] to determine the co-ordination number of aluminium ions in disordered clay minerals and in sodium aluminosilicate glasses respectively This technique for determining the co-ordination number of aluminium ions is described, and the results obtained from examining several materials of widely varying composition are reported

The difference in wave-length of the aluminium *K*α-radiation produced by aluminium ions occupying different co-ordination sites results in a small but measurable angular shift in the position of the aluminium K_α peak Aluminium metal is used as reference material, and the angular position of its K_α peak is compared with the angular position of the aluminium K_α peak for the material in question The experimental quantity which is measured is the difference in these angular positions as expressed by the relationship

$$\Delta°2\theta = °2\theta\ (\text{aluminium metal}) - °2\theta\ (\text{sample}) \qquad (1)$$

This procedure is simpler and may be conducted under simpler experimental conditions than a direct measurement of wave-length

The measurements were made on a General Electric *XRD*-5 diffractometer using a chromium target at 50 kVp. and 40 m amp, a flow proportional counter, a 0 005-in soller slit, and a scanning speed of 0 2°2θ/min A helium path was used to minimize the absorption of the aluminium *K*α-radiation The chart speed was chosen so that 1°2θ was equivalent to 5 in on the chart With these conditions it was possible to measure the peak position, at half-maximum intensity, to ±0 005°2θ The analysing crystal was ethylenediamine ditartrate, with this crystal the peak position for aluminium *K*α-radiation occurs at approximately 142 6°2θ This value of 2θ is large enough so that small differences in wave-

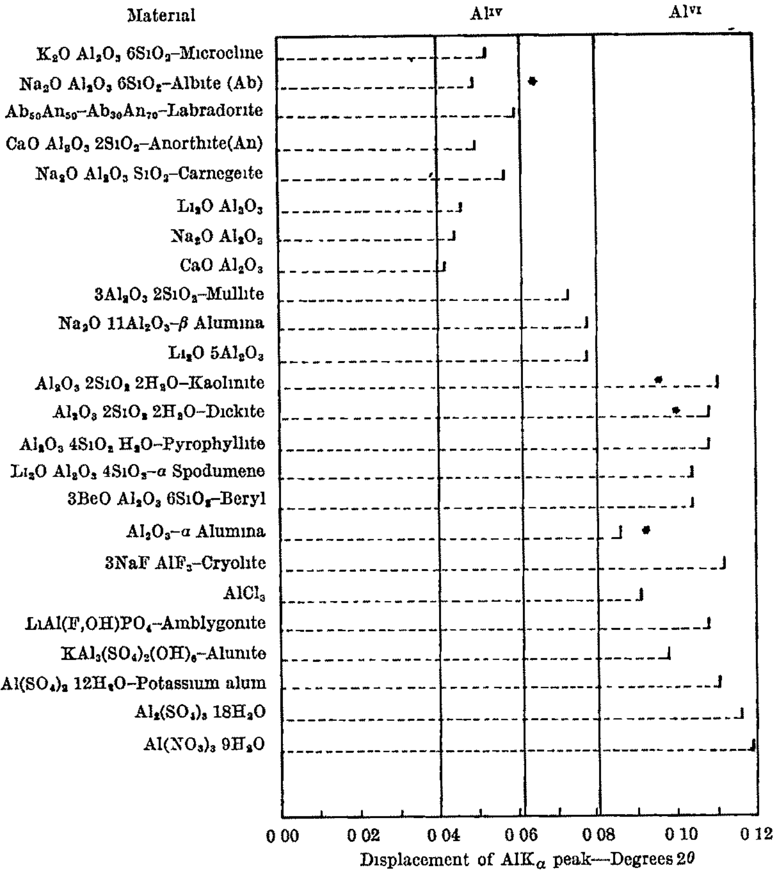

Fig. 1. Displacement of the aluminium K_α peak as calculated from the relationship $\Delta°2\theta = °2\theta$ (aluminium metal) $- °2\theta$ (sample). Al^{IV} and Al^{VI} represent the displacement for materials in which the aluminium ions occupy four-fold and six-fold co-ordination sites, respectively. Asterisks denote displacements reported by Brindley and McKinstry (ref. 3)

length can be detected by measurable shifts in the angular position of the aluminium K_α peak. All the measurements were made at room temperature with the temperature held constant to within ± 1° C. Larger temperature variations were found to change the lattice parameters of the ethylenediamine ditartrate crystal and to cause movement of the diffracted peak position.

Before each measurement, the position of the K_α peak for aluminium metal was determined at least twice. The average of these values was taken as the peak position for aluminium metal. Next, the position of the aluminium K_α peak for the sample material was determined at least twice. The angular difference in the position of the aluminium K_α peak for aluminium metal and the sample material was then determined using equation (1).

The displacements of the aluminium K_α peak, that is, the angular differences between the position of the aluminium K_α peak for aluminium metal and for the materials which have been studied, are shown in Fig. 1. The materials are arranged in the order (*a*) materials with aluminium ions occupying four-fold co-ordination sites, (*b*) materials with aluminium ions occupying more than one co-ordination site, (*c*) materials with aluminium ions in six-fold co-ordination sites. The displacements of the aluminium K_α peak for the first eight materials all occur within the range 0.040–0.061°2θ. Similarly, the displacements of the aluminium K_α peak for the materials kaolinite through $Al(NO_3)_3 9H_2O$ all occur within the range 0.080–0.120°2θ. These two regions are shown in Fig. 1 as Al^{IV} and Al^{VI}, and denote aluminium ions occupying four-fold and six-fold co-ordination sites, respectively.

The crystal structures of the materials microcline through $CaO Al_2O_3$, excluding $Li_2O Al_2O_3$, are known, and the aluminium ions in these materials occupy four-fold co-ordination sites. No information could be found for the crystal structure of $Li_2O Al_2O_3$, but the displacement of the aluminium K_α peak indicates that the aluminium ions in this material occupy four-fold co-ordination sites also.

The displacements of the aluminium K_α peak for mullite, β-alumina, and $Li_2O 5Al_2O_3$ as shown in Fig. 1 are between the regions indicated for aluminium ions occupying four-fold and those occupying six-fold co-ordination sites. These intermediate displacements indicate the aluminium ions in these three materials occupy more than one kind of co-ordination site. β-Alumina and $Li_2O Al_2O_3$ have the spinel structure with the aluminium ions distributed among four- and six-fold co-ordination sites. Similarly, the crystal structure of mullite, which resembles that of sillimanite[5], is believed to contain aluminium ions in both four- and six-fold co-ordination.

The displacements of the aluminium K_α peak for the remaining materials shown in Fig. 1 indicate that the aluminium ions in these materials occupy sites of six-fold co-ordination. The crystal structures of the materials kaolinite through potassium alum are known and confirm the existence of aluminium ions in six-fold co-ordination sites. No crystal structure information, which included the co-ordination number of the aluminium ions, could be located for $Al_2(SO_4)_3 18H_2O$ and $Al(NO_3)_3 9H_2O$. The displacement of the aluminium K_α peak for these two compounds indicates the aluminium ions should occupy six-fold co-ordination sites.

While the change in wave-length of the aluminium $K\alpha$-radiation resulting from a change in the co-ordination number of the aluminium ions is apparent in Fig. 1, the kind of anion surrounding the aluminium ion also has a small effect on the wave-length, as illustrated by $3NaF AlF_3$ and $AlCl_3$. The aluminium ions in these two compounds occupy six-fold co-ordination sites, but the displacements of the aluminium K_α peak for these compounds is 0.112 and 0.091°2θ respectively. If this trend were to continue for $AlBr_3$, it would be predicted that the aluminium ions in $AlBr_3$ should occupy four-fold co-ordination sites, since the displacement of the aluminium K_α peak would be close to the range indicated in Fig. 1 for materials containing aluminium ions in four-fold co-ordination sites. The direction of the trend indicated by $3NaF AlF_3$ and $AlCl_3$ is substantiated by the reported crystal structure for $AlBr_3$ (ref. 6) which places the aluminium ions in four-fold co-ordination sites. The influence of the kind of anion surrounding the aluminium ion has also been noted by Brindley and McKinstry[3]. They found the displacement of the aluminium K_α peak for aluminium nitride, which contains aluminium ions in four-fold co-ordination sites, differed significantly from the displacements for materials in which the aluminium ions occupied four-fold co-ordination sites, but were surrounded by oxygen ions rather than nitrogen ions.

The technique described here is simple and can be easily used for a variety of materials. Unlike X-ray diffraction, it is equally suitable for crystalline and for 'amorphous' materials having short-range order. The task of determining the presence or absence of various structural groups in amorphous materials is difficult, and in many instances structural models have been proposed on the basis of physical property measurements. This technique should be useful, therefore, in elucidating the structural groups which are thought to exist in certain amorphous materials

DEGRADATION PRODUCTS FROM ELASTIN

Partial Structure of Two Major Degradation Products from the Cross-linkages in Elastin

THE isolation and preliminary examination of two new amino-acids derived from the cross-linkages in elastin have already been reported[1] These compounds, designated *A* and *M*, were provisionally assigned the empirical formulæ $C_{26}H_{45}N_5O_8$ and $C_{26}H_{41}N_5O_8$ respectively They have now been isolated on a larger scale directly from the acid hydrolysis products of purified elastin from bovine ligamentum nuchae, and in this communication a partial structure for both compounds is proposed

Titration experiments with *A* and *M* previously reported[1] indicated a minimum molecular weight of about 272 for both compounds, and each showed groups titrating with mid-points near *p*H 1 70, 2 40, 8 80 and 9 85 From the titration curves an iso-ionic point in the region of *p*H 5 6 would be expected, but electrophoretic mobility determinations in phosphate–citrate or sodium barbitone buffers have now shown that the isoelectric point is near *p*H 8 5 for both compounds It is thus concluded that both compounds contain a very strongly basic group, probably quaternary ammonium, which titrates above *p*H 11 5 Inspection of the titration curves shows that the alkaline isoelectric point is brought about by the presence of 0 5 equivalents of the strongly basic group in 270 g and thus the molecular weight of both substances is at least 540 In the course of the electrophoresis experiments it was observed that in buffers containing carbonate both compounds had a high net negative charge at *p*H 8 5 although the charge is zero in the absence of carbonate at this *p*H This suggests that the compounds bind carbonate ion with unusual avidity when this ion is in excess Alternatively, a carbamino compound may be formed

On treatment of compound *A* with nitrous acid in the apparatus of Van Slyke[2], 79 per cent of the total nitrogen was recovered as N_2 the value for compound *M* was 78 per cent, thus indicating that with both compounds four-fifths of the nitrogen was bound as primary amino groups When oxidized with ninhydrin by the gasometric procedure of Van Slyke *et al* [3] carbon dioxide was released equivalent to 78 per cent of the total nitrogen for compound *A* and 77 per cent for compound *M*, showing that four nitrogen atoms out of five were combined as α-amino-acid nitrogen for both compounds

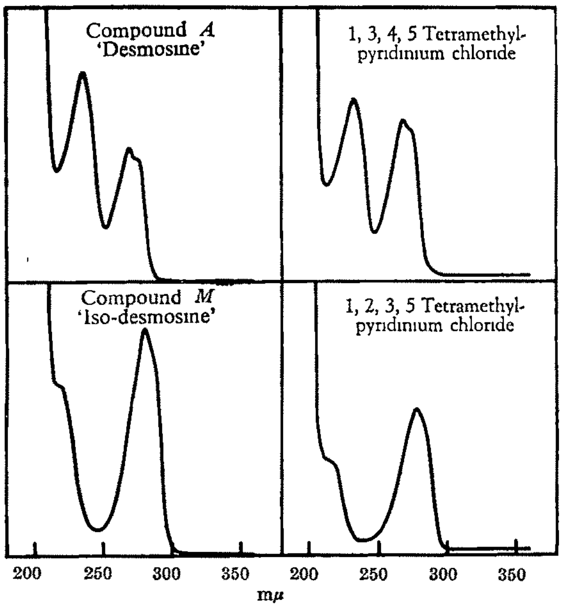

Fig 1

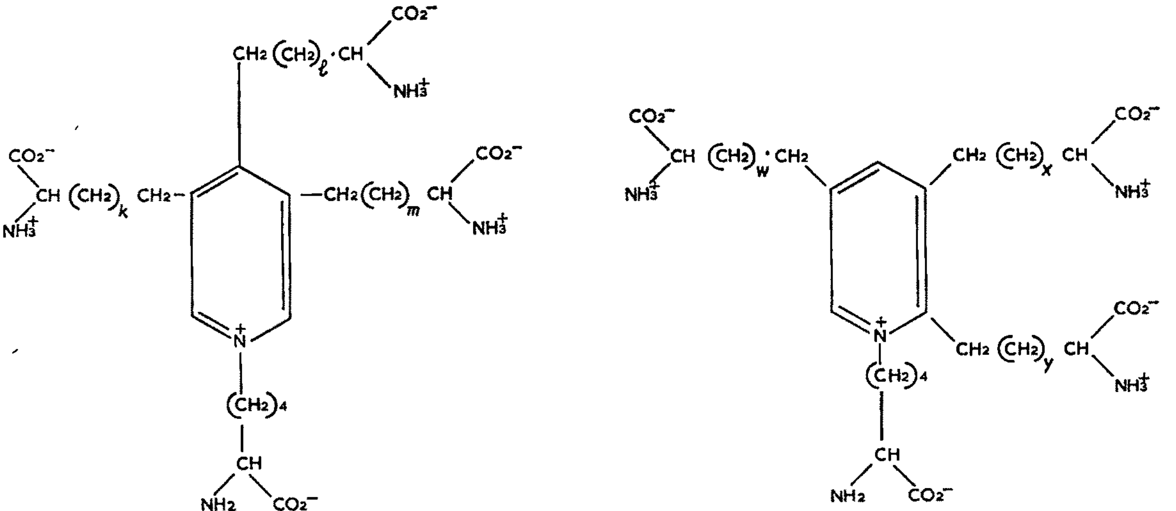
Determination of the molecular weight in aqueous solution using the 'Mechrolab' vapour pressure osmometer



Compound *A*, 'desmosine'

Compound *M*, 'iso-desmosine'

Fig 2

gave values of 524 for *A* and 555 for *M* These values are approximately twice the minimum mol wt determined by titration and suggest that the compounds both contain four α-amino groups, four α-carboxyl groups and one strongly basic group. Difficulty was encountered in drying specimens of the free amino-acids for elementary analysis Both compounds were very hygroscopic and removal of water appeared to be incomplete after several hours under reduced pressure at 100° Analysis of specimens dried in this way showed, for compound *A* C, 52·5, H, 7 5, N, 12 5 per cent, and for compound *M* C, 52 5, H, 7 6, N, 12 6 per cent. ($C_{24}H_{39}N_5O_8\,H_2O$ requires C, 53, H, 7 4, N, 12 8 per cent; mol wt, 543)

It was thought that the difficulty of drying might be due to the presence of the quaternary ammonium group, and to avoid this the chlorides were prepared by titrating the free amino-acids to *p*H 5 6. The chlorides could not be crystallized but the dried products were less hygroscopic and analysed as follows Compound *A* C, 49 9, H, 7 9, N, 12 5, Cl, 5 4 per cent, compound *M* C, 50 0, H, 8 1, N, 12 5, Cl, 5 6 per cent ($C_{24}H_{40}N_5O_8Cl$ requires C, 51 4, H, 7 1, N, 12 5, Cl, 6 3 per cent) From these results it was concluded that compounds *A* and *M* are isomers

On hydrogenation at room temperature and normal pressures with Adams's platinum oxide catalyst in 50 per cent aqueous ethanol or glacial acetic acid solution neither of the isomers took up hydrogen. The presence of aliphatic double bonds is therefore excluded Since both compounds show ultra-violet absorption in the range 260–280 mμ (ref 1) it was inferred that they contain an aromatic nucleus, and since the fifth nitrogen atom cannot be detected as an amino- or imino-group, but appears to form a quaternary ion, it is most probable that the substances are either N-substituted pyridines or N-substituted pyrroles The second alternative is unlikely since ultra-violet absorption spectra[1] of *A* and *M* closely resemble those of the trimethylpyridines and their *N*-methyl quaternary derivatives but differ from those of substituted pyrroles[4] These results, taken together with the marked chemical stability of the compounds under reducing conditions, suggest that the isomers are N- and C-substituted pyridines carrying four saturated aliphatic chains with α-amino-acid terminals Attempts to isolate the nucleus as a pyridine carboxylic acid by oxidation with permanganate resulted in destruction of the nucleus, presumably because of the instability introduced by N-substitution Mild oxidation with ferricyanide at alkaline *p*H also destroyed the nucleus yielding several ninhydrin-reacting degradation products One of these was isolated and identified as lysine This indicated that the structure contains two nitrogen atoms separated by a 5-carbon saturated aliphatic chain, and it was concluded that the pyridine nitrogen is quaternated by an α-amino caproic acid residue

In Fig 1 the ultra-violet spectra of compounds *A* and *M* are compared with those of the 1,3,4,5- and 1,2,3,5-tetramethylpyridinium chlorides The molecular extinctions measured in 0 05 N hydrochloric acid at the maxima were compound *A*, λ268, ε4900; 1,3,4,5-tetramethylpyridinium, λ266, ε4730, compound *M*, λ278, ε7850, 1,2,3,5-tetramethylpyridinium, λ276, ε6940

The proton magnetic resonance spectra reported in the succeeding communication confirm and extend the chemical information given here, and the data together lead to the structures proposed in Fig 2

We propose in future to refer to compound *A* as 'desmosine' and compound *M* as 'iso-desmosine'

We thank Dr A S Bailey, and Dr J. S A Brunskill of the Dyson Perrins Laboratory, Oxford, and Mr H G Willcock of Midland Tar Distillers, Ltd, for the gift of reference samples of trimethylpyridines

Proton Magnetic Resonance Spectra of Degradation Products from Elastin

THE proton resonance spectra of desmosine and iso-desmosine (preceding communication), determined in deuterium oxide, show absorption in five spectral regions The available chemical evidence (preceding communication) and comparison with literature values (Table 1), allowed assignments as in Table 1. Peaks in the aromatic region are sharp singlets, comparison with the isomeric collidine (trimethylpyridine) methiodides indicated that desmosine and iso-desmosine are 1,3,4,5- and 1,2,3,5-tetra-substituted pyridinium salts. The remaining absorptions are broad band-envelopes, probably formed by the overlap of numerous peaks due to several signals of similar chemical shift, and complex coupling The theoretical relative areas given in Table 1 were checked by cutting out and weighing the curves and also by direct integration (on an *A60* machine) All the results were within ± 15 per cent of the theoretical The chemical and nuclear magnetic resonance evidence together lead to the structures of Fig 2 of the preceding communication '*k* + *l* + *m*' in desmosine and '*w* + *x* + *y*' in iso-desmosine are evidently 4

IMMUNOCHEMICAL ANALYSIS OF RABBIT GAMMA-GLOBULIN ALLOTYPES

By Dr. A FEINSTEIN
Agricultural Research Council, Institute of Animal Physiology, Babraham, Cambridge
AND
Prof P G H GELL and Dr. A S. KELUS
Department of Experimental Pathology, University of Birmingham

INTEREST in γ-globulin allotypes[1] (genetically determined variations of γ-globulin) has been increasing in recent years in view of their importance both in genetics and in γ-globulin chemistry They are definable in the rabbit in terms of six known alleles, A1, A2, A3 at one, the *a* locus, A4, A5, A6 at another, the *b* locus[2] Consequently, every rabbit has at least two and not more than four allotypic determinants in its γ-globulin, though 10–20 per cent of the γ-globulin molecules in some sera reported[3] may not carry any known allotypic markers. In this work we have investigated the distribution of the allotypic determinants, both between the whole molecules and on the fragments obtained by recently described degradation techniques

The problem as to whether the allotypic determinants in a given serum are all present on each reacting 7*S* γ-globulin molecule or are in some cases separated can be readily solved by double gel-diffusion analysis, making use of the reactions of identity, and partial or non-identity This is technically complicated by the fact that the antibodies themselves carry allotypic specificities of their own, and for clear results interactions between two adjacent antisera in the cups must be avoided We have been able, however, to demonstrate clearly a reaction of identity without any spurring between determinants at different loci in a homozygous A3,5 rabbit, indicating that all reacting molecules in this case carried both allotypic determinants In a serum examined and reported elsewhere[4], double spurring occurred in this situation In another case, we have shown a reaction of partial identity in an animal heterozygous at one locus (*a*), and homozygous at the other locus (*b*), using an antiserum to an allotypic determinant controlled by a gene at the *a* locus and one against one controlled by a gene at the *b* locus We have been unable to demonstrate unequivocally a reaction of total non-identity in a rabbit heterozygous at both loci, using an antiserum to a determinant controlled by a gene at the *a* locus and an antiserum to one controlled by a gene at the *b* locus respectively Quantitative evidence by other workers[3] has established the fact that in a heterozygote the A4 and A5 allotypes at least can occur on distinct populations of molecules

Turning now to the degradation observations, the allotypic antisera used were monospecific against each of the six known allotypic determinants A goat anti-rabbit antiserum ('Koza') was used which was mainly directed against 7*S* γ but also showed a distinct specific anti-γ-macroglobulin line; another goat anti-rabbit antiserum ('Bab') was used which did not contain this anti-macroglobulin component

Tests were made by double diffusion in 1 per cent agar in plates, and recorded as positive or negative, the concentrations of the reactants being so adjusted as to give a well-defined line

The sera used in the digestion experiments were from four rabbits homozygous at both loci (A1,4; A2,4; A3,4, A3,5), from two homozygous at the *a* locus and heterozygous at the *b* (A1,4,6, A3,4,5), from three homozygous at the *b* locus and heterozygous at the *a* (A1,2,4, A1,3,4; A2,3,4) and from three heterozygous at both loci (A1,3,4,5, A2,3 4 5 A1 2,4,5)

These were fractionated to obtain pure 7*S* γ-globulin and then fragmented (1) by papain digestion and separation of the fragments on carboxymethyl cellulose[5], (2) by mercaptoethanol in *tris* buffer to obtain cleavage into chains, which were then separated by 'Sephadex *G* 75' or '200' gel-filtration in molar propionic acid[6]. Macroglobulin fractions were separated on 'Sephadex *G* 200' gel columns[7]

The starting γ-globulin fractions showed as expected all the allotypes of the original whole sera

The macroglobulin preparations were only satisfactorily pure in two cases (A1,4,6 and A2,3,4,5) as judged by their reacting with goat antiserum 'Koza', and not with goat 'Bab' In both these samples (which happened to contain the full range of allotypes between them) there was a definite reaction with the allotypic determinants controlled by alleles at the *b* locus (A4, A5 or A6) as expected if macroglobulins share the B chain with 7*S* γ-globulins (see following) As regards the components controlled by the *a* locus, doubtful reactions were obtained with A1 and A2 determinants only, tests for A3 determinants were negative A1 and A3 determinants have been reported[8] to be present in purified macroglobulin; this problem clearly merits further investigation

Table 1 RESULTS OF GEL-DIFFUSION REACTIONS SUMMARY OF RESULTS ON TWO SERA COVERING THE WHOLE RANGE OF KNOWN ALLOTYPES. RESULTS WITH OTHER SERA WERE SIMILAR (SEE TEXT)

Rabbit allotype	Preparation	Allotypic antisera anti- −A1	−A2	−A3	−A4	−A5	−A6	Goat anti-rabbit antisera 'Koza'	'Bab'
A1,4,6	7*S* γ-globulin	+			+		+	+	+

,,	A chain		+	+	+	−		+	+
,,	B chain		−	−	+	+		−	−

+, Positive result, −, negative result, ?, weak or doubtful result.

The only papain fraction recorded (Table 1) was fraction I, which could be obtained in a high state of purity; and in every case (four sera covering all the allotypes) all the allotypic components of the original serum were found in this fraction Tests on fraction II gave similar results but of less significance since the fraction was not pure The preparations of fraction III were unsatisfactory

The B (light) chains from all the 12 sera examined showed the presence of the components controlled by alleles at the *b* locus (A4, A5 and A6) and the absence of those controlled at the *a* locus (A1, A2 or A3) (Table 1)

The A (heavy) chain presented some difficulty in purification. Nevertheless, in a number of cases there was no doubt that our preparations possessed the components controlled both by the *a* and by the *b* locus (Table 2)

Starch-gel electrophoresis in urea showed no detectable unreduced 7*S* γ-globulin, but agar-gel immunoelectro-

Table 2 RESULTS OF GEL-DIFFUSION REACTIONS PREPARATIONS OF A (HEAVY) CHAIN

Rabbit allotype	Allotypic antisera anti- −A1	−A2	−A3	−A4	−A5	−A6	Goat anti-rabbit antisera 'Koza'	'Bab'

A1,2,4,5	+	+		+	−		+	+
A1,4,6	+			−		+	+	+

phoresis of A chain fractions showed, with anti-A4 antiserum, that A4 moved with the A chain, and was not detectable in the more anodic position, where, in the absence of A chain, free B chain is found Free B chain could not, however, be expected, since immunoelectrophoresis shows recombination to be complete when a mixture of A and B chains in propionic acid is neutralized

Our results leave us in no doubt that the B (light) chain of 7*S* γ-globulin (which is shared with γ-macroglobulin) possesses the allotypic determinants A4, A5 and A6 controlled by alleles at the *b* locus

The results with A (heavy) chains are technically somewhat unsatisfactory and difficult to interpret on the reasonable genetic assumption that the A and B chains are correlated with the *a* and *b* loci respectively One would expect only the determinants controlled by alleles at the *a* locus (A1, A2 and A3) to be represented on the A (heavy) chain, as those from the *b* locus (A4, A5 and A6) certainly are on the B (light) chain We were, however, quite unable to separate anti-A4 reactivity from the A chain preparation in nearly all cases in one case out of five A5 was demonstrable, and in the preparation from A1,4,6 serum, A6 was demonstrable Attempts at further purification in 'Sephadex *G* 200' did not materially alter these results

There seem at least two possibilities either (1) that indeed the genes of the *b* locus are in control of determinants both on the B and on the A chains (for example, the determinants may be prosthetic groups added after the synthesis of the polypeptide chains), or (2) that the separation of A and B chains is not complete, and that too much B chain contaminates A chain preparations to allow of the application of qualitative methods such as those we have used Even with such methods, however, the intensity of the anomalous reactions which we have observed would imply that such contamination must be remarkably great

The reactions of the macroglobulins are consistent with expectation, in so far as the B (light) chain is supposed to be common to 7*S* γ-globulin and the γ-macroglobulin, and the allotypic determinants A4, A5 and A6 were readily demonstrable in both If it were assumed that immune globulin molecules contain only two types of polypeptide chain, one might expect, since the A chains of 7*S* γ-globulin and of γ-macroglobulin are antigenically different, that allotypic determinants A1, A2 and A3 would be lacking in the macroglobulins Our results leave this question still undecided Other macroglobulin preparations gave two lines with the goat anti-rabbit serum ('Koza') (which possessed both anti-7*S* γ- and anti-γ-macroglobulin specificity), one of which showed identity with 7*S* γ-globulin in these preparations, which we rejected as impure, the allotypic determinants A1, A2 and A3 were readily demonstrable

The results with the papain digest, Fraction I, show that the allotypic determinants are resistant to this type of degradation (see also refs 9 and 10) They indicate that the determinants A1, A2 and A3 must be present in the part of the A chain which is complexed with the B chain in papain fraction I, whether they are also present in the other part of the A chain, represented by the crystalline fraction III, could not be definitely established owing to the poor solubility and doubtful purity of these fractions

The study of the distribution of allotypic determinants between molecules is clearly only in a preliminary stage So far as our results go they are consistent with the genetic interpretation that in a homozygous A3,5 animal all the reacting molecules are A3,5, in an A2,3,6 animal they are either A2,6 or A3,6, in an A2,3,4,5 animal the situation is more complicated and we cannot exclude the occurrence of the combination A2,4 + A3,4 + A2,5 + A3,5 (see also ref 4) Further work along these lines with more suitable antisera is in progress

IMMUNOLOGICAL TOLERANCE BETWEEN LITTER-MATES IN SHEEP

By Dr J. SLEE

Agricultural Research Council, Animal Breeding Research Organization, Edinburgh, 9

It is known that placental vascular anastomosis occurs in most twin pregnancies in cattle If the anastomosed twins are of unlike sex the female becomes a freemartin (intersex) It has also been shown[1] that most twin calves of all sexes show mutual tolerance of skin homografts, presumably as a result of embryonic vascular anastomosis In sheep, where twins are far more frequent, both embryonic vascular anastomosis and freemartinism have been regarded as rare[2–7] One ♂ ⚥ (freemartin) pair has been described[3] in which the twins were tolerant of reciprocal skin homografts At least one other case of skin homograft tolerance in sheep has been reported between two members of a triplet litter[4] Probably embryonic vascular anastomosis, which causes blood cell mosaicism[2], is a necessary pre-condition for all cases of freemartinism and tissue tolerance between litter-mates in cattle and sheep The frequency of embryonic anastomosis between sheep twins has been estimated at 5–10 per cent[2,4] There is independent evidence also that the frequency of blood mosaicism in twins may be about 5 per cent[2] It is possible that anastomosis of placental blood vessels does not always produce post-natal blood cell mosaicism Independent estimates of the frequency of immunological tolerance among sheep litter-mates are scarce (Table 1)

The foregoing results, if taken provisionally at their face value, suggest the possibility of implanting sheep embryos of widely different genotypes adjacently in the same uterus, so that in a certain small proportion

Table 1 FREQUENCY OF IMMUNOLOGICAL TOLERANCE AMONG SHEEP LITTER-MATES

* These numbers are doubled to assess the proportion of tolerant lambs

† Some lambs died before being grafted, survivors in these litters were grafted

of cases vascular anastomosis might occur, making such embryos immunologically tolerant If sheep of different breeds could be made mutually tissue-tolerant this would be of interest to (among others) the reproductive physiologist (transfer of ovaries), or the wool biologist (transfer of skin between sheep showing different wool growth patterns) Co-existing embryos of 50 per cent different breed genotype can be obtained by double mating ewes with rams of different breeds, so giving bi-paternal litters[8] Or, preferably, the techniques of transfer of ova[9,10] would allow fertilized eggs of 100 per cent different breed genotype to be implanted in the same uterus The most likely limiting factor would be the low frequency of embryonic vascular anastomosis It was therefore important (*a*) to assess the natural frequency more accurately, (*b*) to maximize it by experimental or other means For a relatively high frequency of anastomosis it was thought that large litters, causing uterine crowding, might be desirable It has been shown that uterine crowding increases the incidence of fused placentæ in mice[11]

The question of obtaining immunological tolerance between sheep litter-mates was therefore approached as follows To estimate the frequency of embryonic vascular anastomosis in large litters, lambs belonging to litters of three or more were tested by skin homografts from each other On each of the lambs, which were taken first at about 6 months of age, 3 homografts were accompanied by 3 control autografts All grafts were either 1 or 2 cm diameter, full thickness The criteria for tolerance were absence of homograft reaction, survival of homograft tissue for at least 6 months with the production of wool, and absence of a line scar Some of the large litters used were obtained naturally, some were produced by super-ovulation In some cases ewes were each mated to several rams of different breeds, producing bi- and tri-paternal litters From some litters placentæ were recovered intact at birth They were usually injected via the umbilical vessels with 'Neoprene' dye latex and examined for evidence of vascular anastomosis

The results of this work were briefly as follows Skin grafts were made on 66 lambs surviving from 7 sets of twins, 14 sets of triplets, 4 sets of quadruplets, and on 2 lambs surviving from a quintuplet litter Clear tolerance towards homografts was found between 3 pairs of lambs Two of these pairs were members of a quadruplet litter of Welsh Mountain lambs produced after super-ovulation of the ewe *A* ♂ and *D* ♀ were mutually tolerant, and *B* ♂ and *C* ♀ were likewise The other combinations showed no tolerance *D* was a freemartin (female external genitalia with enlarged clitoris, plus small undescended testes, male horn type and male sex behaviour) *C* was barren when mature but showed no external signs of freemartinism

First set skin grafts from *D* to *A* and *B* to *C* grew wool and were still present 1½ years after transplantation Second set grafts survived less well *D* to *A* second set grafts were rejected in 3 months although the first set grafts remained healthy during the same period Part of the second set grafts from *B* to *C* survived for more than a year, but the rest of the graft tissue appeared to be gradually lost The first set grafts again remained healthy First set reciprocal grafts of *A* to *D* and *C* to *B* survived for 6–9 months before being rejected

These sheep were tested for red blood cell mosaicism at about 1½ years of age by Dr Stormont of the University of California Mosaicism was detected between *A* and *D* (the freemartin), although in *A* one of the cell types had almost completely regressed No mosaicism was apparent in *B* and *C* but it could have existed at an earlier stage Two points emerge from these data First, homograft tolerance, which is probably caused or at least permitted by erythrocyte mosaicism, can persist after the mosaicism has regressed Secondly, first set grafts can be tolerated at the same time as second set grafts from the same donor appear to be slowly rejected Rejection of the second grafts could be related to the regression of the donor blood cells if this tells preferentially against the new grafts rather than the established ones The placenta was not recovered from this litter

The third pair of lambs showing mutual homograft tolerance were Merino–Blackface crosses (♂♂) surviving from a triplet litter produced after super-ovulation Here, first set grafts from *A* to *B* are still surviving now after 9 months Reciprocal homografts from *B* to *A* were less uniformly successful, but some of the donor tissue remains after 9 months The placenta, when recovered at birth, showed clear anastomosis of major veins between 2 of the original 3 embryos The lambs have not yet been tested for blood mosaicism Apart from this instance there have been two other cases of placental anastomosis of major blood vessels—both in triplet litters (Table 2) In the first of these (as in the case here) only 2 lambs survived, they showed only slight asymmetrical homograft tolerance Reciprocal grafts survived 4 and 7 weeks respectively, compared with the normal within-litter rejection time of 2–3 weeks Presumably one of these surviving lambs had been anastomosed with the dead lamb, and for that reason may have been tolerant of a wider than normal range of antigens The 3 lambs in the remaining litter showing placental vascular anastomosis have not yet been skin grafted In addition to these 3 cases of major vessel anastomosis, 2 other placentæ have shown fusion of minor capillary vessels derived from different embryos The significance of this is not known

Table 2 FREQUENCY OF PLACENTAL VASCULAR ANASTOMOSIS IN SHEEP LITTERS

	No Total	From twins	From triplets	From quads	From quins
Placentæ examined	20	11	5	3	1 (part only)
Cases of major vessel fusion between embryos	3	0	3	0	0
Cases of minor vessel fusion between embryos	3	2	0	1	0

General conclusions are as follows Embryonic vascular anastomosis does occur in large sheep litters with a frequency perhaps rather higher than might have been expected For the highest frequency of anastomosis large litters may be better than twins (Table 1), but the evidence for this is obviously not conclusive Embryonic anastomosis in sheep can be between major blood vessels, and then it appears to confer in some, perhaps all, cases a degree of post-natal immunological tolerance on the surviving lambs involved This may be accompanied by blood cell mosaicism for at least some time after birth Where anastomosis is between ♂ and ♀ embryos, freemartins may occur perhaps invariably but not always overtly The possibility that covert freemartinism causing female infertility may occur fairly frequently was examined on a statistical basis by comparing the fertility of 187 ewes which had been born twin to ♀♀ with the fertility of 167 ewes born twin to ♂♂ No difference was found The apparent rarity of freemartinism in twin litters could be connected with the high frequency of transuterine migration of ova in sheep[12] Nevertheless, the arrangement of the embryonic membranes and vascular system is such that anastomosis might occur even between embryos implanted in different horns of the uterus

The information discussed here, coupled with the proved technique of ova transfer, indicates that it would be difficult, but perhaps possible, to induce within-litter immunological tolerance in sheep and use it to transplant tissue between individuals of different breeds Although natural embryonic vascular anastomoses are not common, they may offer the best chance of success, since sheep embryos develop immunity early in gestation[13], thus making it difficult to produce tolerance experimentally[14] However, even if anastomosis can be induced sufficiently frequently between sheep embryos of different breeds, it remains to be seen whether the tolerance conferred is sufficient to bridge the between-breed immunological barrier

This work is now being extended in collaboration with Dr J L Hancock, whom I thank

EFFECT OF METHAQUALONE HYDROCHLORIDE IN PREGNANT RABBITS AND RATS

By R G BOUGH, DR M R GURD, DR J E HALL and DR. B LESSEL

Research Department, Boots Pure Drug Co , Ltd , Nottingham

FOLLOWING the thalidomide disaster, attention has been directed to the need to test drugs for possible teratogenic activity Many drugs have recently been subjected to teratogenesis tests, in the laboratories of the pharmaceutical industry and elsewhere, but little of this work has yet been published, probably because of the difficulty of interpreting the results The picture which seems to be emerging is that there may be no drugs or chemical substances which are completely free from any effects on the fœtus, most substances which have so far been tested on experimental animals show toxic effects on the fœtus if they are administered to the mother in large enough doses This is not surprising, for if a substance were given to the mother in doses large enough to be toxic to her, it would be strange indeed if the fœtus was not affected

A possibly useful new drug is not rejected because it causes death in experimental animals when given in excessive doses; almost every drug does so Similarly, a drug need not necessarily be rejected because it causes death or abnormalities in the fœtuses of experimental animals when given to the mother in excessive doses Only experience can teach us to interpret the results of teratogenesis tests in experimental animals in terms of possible human hazards, and it is therefore important that work of this kind should be published, even if it does not at present answer all our questions

In the present state of knowledge a useful guide is the relation between the toxic dose of a drug to the fœtus and the toxic dose to the mother, if these two doses are about the same, that is, if the fœtus is no more susceptible to the toxic effects of the drug than is the mother, it is reasonable to suppose that the drug has no specific teratogenic effect

This article describes the results of animal experiments with methaqualone hydrochloride, and is intended both to give some guidance on the degree of risk attached to this drug, and to serve as an example of the kind of results which are likely to occur with many drugs in common use Methaqualone hydrochloride (2-methyl-3-*o*-tolyl-4-quinazolone hydrochloride, 'Melsedin', 'Tuazole') is a hypnotic drug, with a therapeutic dose up to 300 mg (about 5 mg/kg)

The first experiment we carried out was a comparison of the effects of methaqualone and thalidomide in rabbits, using the technique by which Somers[1] has successfully demonstrated the teratogenic action of the latter drug New Zealand White and Californian rabbits weighing 2 5–4 kg were used Each drug was given by mouth in a dose of 500 mg per rabbit daily, starting on the 8th day of pregnancy and continuing to the 13th day with thalidomide and the 15th or 16th day with methaqualone The mothers were killed the day before parturition was expected; each fœtus was examined internally and externally for abnormalities, radiographed and cleared and stained with alizarin red for detailed examination of the skeleton The results of this experiment are summarized in Table 1 Thalidomide treatment increased the proportion of fœtuses dying *in utero* and caused abnormalities in 80 per cent of the live fœtuses The abnormalities included skeletal defects such as those described by Somers[1] and others[2], and cerebral defects similar to those described by Giroud[3] and Felisati[4], in addition we observed five fœtuses with one kidney absent (four of them in one litter), which we believe has not been reported previously in experimental animals, although it has been described in man[5] Methaqualone treatment, in contrast, had no effect on the survival of fœtuses *in utero*, and no abnormalities were found

Table 1 EFFECT OF THALIDOMIDE AND METHAQUALONE IN PREGNANT RABBITS

	No of mothers*	No of fœtuses				Average live litter size	Implants dead or resorbed (%)
		Live normal	Live abnormal	Dead	Resorbed		
Controls	4	27	0	1	3	6 8	12 9
Methaqualone 500 mg/day							
Days 8–15	3	27	0	3	0	9 0	10 0
Days 8–16	3	33	0	0	4	11 0	10 8
Thalidomide 500 mg/day							
Days 8–13	7	5	22	1	30	3 9	53 4

* Animals originally included in the experimental groups but later found not to be pregnant have not been included in these four Tables

In the second experiment with methaqualone in rabbits three dose-levels were used, the doses were related to body weight, and dosing was continuous throughout pregnancy from the 1st to the 29th days, in other respects the technique was unchanged The results are summarized in the first part of Table 2 Two of the 79 fœtuses from animals treated with one or other dose of methaqualone showed abnormalities, and a third experiment was therefore performed using the same technique, but with larger groups of rabbits and one level only of methaqualone; the results of the third experiment are summarized in the second part of Table 2. Taking these two experiments together, there was no evidence that treatment with methaqualone, at 100 or 200 mg/kg/day, affected live litter size or increased the incidence of deaths *in utero*. Treatment at 400 mg/kg/day reduced the number of implants per animal, without affecting the survival of implanted fœtuses, which suggests interference with blastocyst development. Abnormalities of various kinds occurred in the fœtuses of both treated and control animals; these are listed in Table 3. We deal first with the least important condition, which we have described as 'hypoplasia of the gall bladder'. The gall bladder in rabbit fœtuses shows great variation in size, and is invisible to the naked eye in about 5 per cent of control animals; this condition we have noted as 'hypoplasia', although in every case the bile ducts are patent and there is no reason to believe that biliary function is abnormal. This condition appears to represent one extreme of the normal range of variation, and we do not regard it as a malformation. Next come the conditions which occurred with equal frequency in the treated and control groups and cannot therefore be attributed to treatment, that is, unilateral pelvic kidney, absence of a lobe of the lung, and minor abnormalities of the calcification centres in the sternum. Lastly, there are a few abnormalities which were observed in treated animals but not, in this experiment, in controls. Two of these conditions, rotation of a forelimb and deficient phalangeal development of a hind foot, have been observed in untreated rabbits in other experiments, and a third, fusion of rib heads, occurred only with a dose high enough to kill one of the adults. This leaves two abnormalities which occurred in rabbits receiving non-lethal doses of methaqualone, and which we have not so far seen in control fœtuses, that is, absence of a pollex and a jejunal diverticulum.

Table 2. EFFECT OF METHAQUALONE IN PREGNANT RABBITS

	No. of mothers	Adult deaths	No. of fœtuses Live	Dead	Re-sorbed	Average live litter size	Implants dead or resorbed (%)
Second Exp.							
Controls	4	0	34	1	1	8·5	5·5
Methaqualone 100 mg/kg/day	5	0	32	3	5	6·4	20·0
Methaqualone 200 mg/kg/day	4	0	30	1	7	7·5	22·2
Methaqualone 400 mg/kg/day Days 1–29	3	1	17	0	0	5·7	0
Third Exp.							
Controls	15	0	119	15	17	8·0	21·2
Methaqualone 100 mg/kg/day Days 1–29	18	0	139	17	16	7·7	18·1

Table 3. FŒTAL ABNORMALITIES IN RABBITS

	No. of fœtuses affected			
		Methaqualone: days 1–29		
	Controls	100 mg/kg/day	200 mg/kg/day	400 mg/kg/day
Skeletal abnormalities visible externally				
Rotation of a forelimb*		1		
Deficient phalangeal development of a hind foot*		1		
Absence of a pollex		1		
Skeletal abnormalities found by X-ray or staining				
Fusion of two rib heads on one side				1
Minor abnormalities of sternal calcification centres†	2	2		
Visceral abnormalities				
Jejunal diverticulum		1		
Unilateral pelvic kidney	1	1		
Absence of one lobe of lung	1	1		
"Hypoplasia" of gall bladder	7	14		
Total number of fœtuses	153	171	30	17
Number of fœtuses of which skeletons were stained†	119	139		

* These two conditions did not occur in control animals in these experiments, but have been found in control rabbits in other experiments.

† Minor abnormalities of sternal calcification centres would be detected only in stained skeletons.

The position in the rabbit is complicated by the occurrence of spontaneous abnormalities in 2–3 per cent of control fœtuses. The number of fœtuses showing abnormalities of one kind or another was slightly greater in the methaqualone-treated animals than in the controls, but the difference was far too small to have statistical significance, although more than 370 fœtuses were included in the comparison. A more important point is that each type of abnormality in the fœtuses from methaqualone-treated mothers occurred only once; there was no characteristic pattern of malformation. By contrast, thalidomide treatment increased the incidence of abnormality from about 3 to about 80 per cent of fœtuses, and gave a characteristic pattern of skeletal and cerebral defects.

Other experiments were done in rats. Newly mated female albino rats were given methaqualone hydrochloride daily by oral intubation at four dose-levels from the 1st to the 20th days of pregnancy; the animals were killed on the 21st day (the day before parturition was expected) and the fœtuses examined as previously described. The results are summarized in Table 4. The highest doses, 100 and 75 mg/kg/day, caused maternal deaths and increased the incidence of deaths *in utero*; among the 77 live fœtuses from animals receiving these doses three were abnormal; one with omphalocœle and one with complete cleft palate on 75 mg/kg, and one with extensive subcutaneous œdema on 100 mg/kg. The next lower dose, 50 mg/kg/day, caused neither maternal nor fœtal deaths, but reduced gain in body-weight in the mothers; no abnormalities were observed in the fœtuses from these animals. Examination of the stained skeletons showed apparent defects of calcification in the sternal centres and elsewhere in some animals on doses of 50 mg/kg/day upwards; further experiments in which rats given 50 mg/kg/day were allowed to survive to parturition showed that at this dose calcification was merely delayed for 24 or 48 h. The lowest dose, 25 mg/kg/day, had no effects of any kind, and no abnormalities occurred in the fœtuses from these animals or the controls.

Table 4. EFFECT OF METHAQUALONE IN PREGNANT RATS

	No. of mothers	Adult deaths	No. of fœtuses Live normal	Live abnormal	Dead	Re-sorbed	Average live litter size	Implants dead or resorbed (%)
Controls	12	0	101	0	0	7	8·4	6·5
Methaqualone 25 mg/kg/day	8	0	85	0	1	2	10·6	3·4
Methaqualone 50 mg/kg/day	9	0	79	0	0	7	8·8	8·1
Methaqualone 75 mg/kg/day	7	1	53	2*	3	15	7·6	25·5
Methaqualone 100 mg/kg/day	5	2	24	1†	7‡	6	4·8	35·2

* One omphalocœle and one cleft palate.

† Extensive subcutaneous œdema.

‡ All the dead fœtuses were in a single litter.

The threshold dose for methaqualone to produce minimal toxic effects in the rat mother and fœtus was about 50 mg/kg/day. These minimal toxic effects consisted of reduction of growth in the mother and delayed skeletal calcification in the fœtus. The important point is that the threshold dose was the same for mother and fœtus; at higher doses some of the mothers died, and the incidence of abnormal fœtuses increased from zero to about 4 per cent. The fact that the drug was toxic to the fœtus only in doses at which it was also toxic to the mother indicates that it lacks specific teratogenic activity.

The conclusion we draw from the results reported here is that methaqualone shows no specific teratogenic activity in rabbits and rats, and is therefore unlikely to present a hazard to the human fœtus in therapeutic use.

HÆMOGLOBINS N AND P IN ITALIAN FAMILIES

By Prof. E. SILVESTRONI, I. BIANCO and C. BRANCATI

Istituto d'Igiene dell'Università di Roma,
Centro di Studi della Microcitemia e delle Anemia Microcitemiche, Roma

Frequency and Characterization of the Hæmoglobin N

IN our laboratory, four family stocks, carriers of hæmoglobin N, have been observed so far: the first one, already described[1], is of Sardinian origin, the other three originate from Calabria. The electrophoretic mobility and the other physical-chemical characteristics are identical in all the four stocks and fully correspond to those of hæmoglobin N: that is, at alkali *p*H (Fig. 1) the electrophoretic mobility is greater than that of hæmoglobin A, with a distinct separation from it; at acid *p*H the cathode mobility is slightly less than that of hæmoglobin A, so much so that it forms at the end of electrophoresis an oblong hæmoglobin spot; on agar gel at acid *p*H the mobility is the same as that of hæmoglobin A; on 'Amberlite *IRC*-50' chromatography at *p*H 6, the mobility is greater than that of hæmoglobin A with a distinct separation from it (Fig. 2). The hæmatologic characters are normal and the percentage of hæmoglobin N oscillates from 19 to 36.

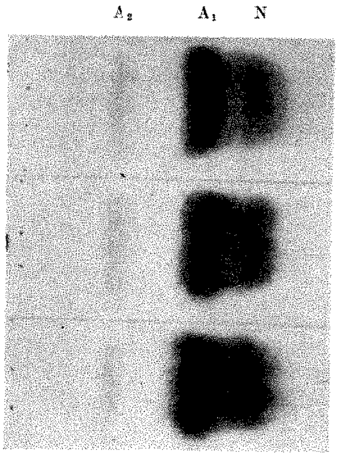

Fig. 1. Paper electrophoresis of hæmoglobin N belonging to three different families. Glycine buffer *p*H 8·8, ionic strength 0·04. Staining with bromphenol blue

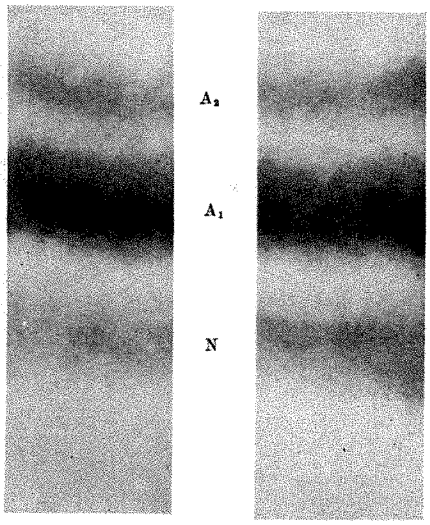

Fig. 2. Chromatography on columns of 'Amberlite *IRC*-50' of hæmoglobin N belonging to two different families. Citrate buffer *p*H 6, ionic strength 0·05. Hæmoglobin N precedes hæmoglobin A and separates clearly from it

Hybridization and recombination experiments carried out with the technique of Itano and Robinson[2], adapted to the micromethod by Gammack *et al.*[3], have revealed, in three of these stocks in which it has been possible to conduct the research, that the abnormal hæmoglobin is altered in the α-chain.

It has been ascertained that hybridization of hæmoglobin N with hæmoglobin L_{Ferrara} (which is altered in the α-chain[4]) does not produce any new hæmoglobin fraction (Fig. 3), while hybridization with hæmoglobin S (which is altered in the β-chain) produces an abundant portion of hæmoglobin A (Fig. 4), which appears also in hybridization of hæmoglobin N with hæmoglobin H. It is evident that in these hybridizations the products foreseen in the following equations are formed:

$$\begin{array}{ccccccc} \alpha_2^N\beta_2^A & + & \alpha_2^L\beta_2^A & = & \alpha_2^N\beta_2^A & + & \alpha_2^L\beta_2^A \\ \text{Hb N} & & \text{Hb L} & & \text{Hb N} & & \text{Hb L} \end{array}$$

$$\begin{array}{ccccccccccc} \alpha_2^N\beta_2^A & + & \alpha_2^A\beta_2^S & = & \alpha_2^N\beta_2^A & + & \alpha_2^A\beta_2^S & + & \alpha_2^A\beta_2^A & + & \alpha_2^N\beta_2^S \\ \text{Hb N} & & \text{Hb S} & & \text{Hb N} & & \text{Hb S} & & \text{Hb A} & & \text{Hb N/S} \end{array}$$

Hybridization of hæmoglobin N with canine hæmoglobin does not give rise to any new hæmoglobin fraction. This fact too shows that the structural alteration concerns the α-chain. In fact, if the alteration affected the β-chain, a hybrid ($\alpha_2^{can}\beta_2^N$) faster than hæmoglobin N and a hybrid ($\alpha_2^A\beta_2^{can}$) slower than canine hæmoglobin should appear; on the contrary, only two fractions are formed which correspond, in mobility, one to canine hæmoglobin and the other to hæmoglobin N: the first very probably contains, besides canine hæmoglobin, also the hybrid $\alpha_2^N\beta_2^{can}$ for which an electrophoretic position equal to that of canine hæmoglobin is expected and the second contains, besides hæmoglobin N, also the hybrid $\alpha_2^{can}\beta_2^A$, the

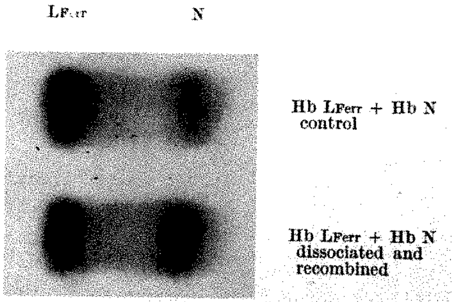

Fig. 3. Hybridization of hæmoglobin N with hæmoglobin L_{Ferrara}. Discontinuous buffer system, *p*H 8·2, ionic strength 0·06, *o*-dianisidine stain. No new hæmoglobin appears

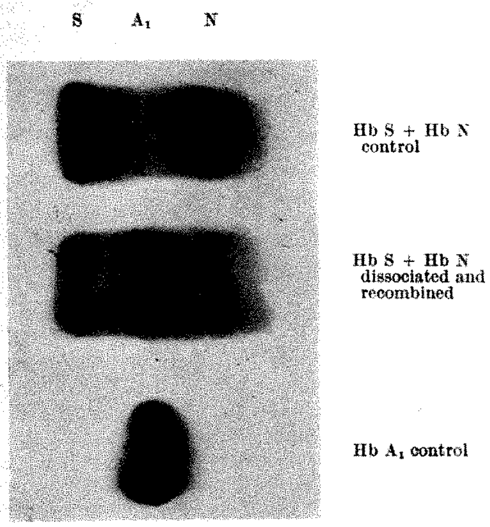

Fig. 4. Hybridization of hæmoglobin N with hæmoglobin S. Discontinuous buffer system, pH 8·2, ionic strength 0·06, o-dianisidine stain. In the dissociated and recombined mixture a new hæmoglobin appears, migrating at the same rate as hæmoglobin A

mobility of which is expected to be equal to that of hæmoglobin N. In this hybridization the products foreseen in the following equation are formed:

$$\underset{\text{Hb N}}{\alpha_2^N\beta_2^A} + \underset{\text{Hb}_{\text{can}}}{\alpha_2^{can}\beta_2^{can}} = \underset{\text{Hb N}}{\alpha_2^N\beta_2^A} + \underset{\text{Hb}_{\text{can}}}{\alpha_2^{can}\beta_2^{can}} + \alpha_2^N\beta_2^{can} + \alpha_2^{can}\beta_2^A$$

On the basis of these results, the conclusion can be drawn that the hæmoglobin N observed in various regions in Italy is characterized by a structural alteration of the α-chain, while the presence is reported, in literature, in other countries, of hæmoglobin N altered in the β-chain[3].

After hæmoglobin D, hæmoglobin L and hæmoglobin G, this is a new example of hæmoglobin, which, although having the same electrophoretic and physical-chemical characteristics, has its specific structural alteration once in α-chain, once in β-chain.

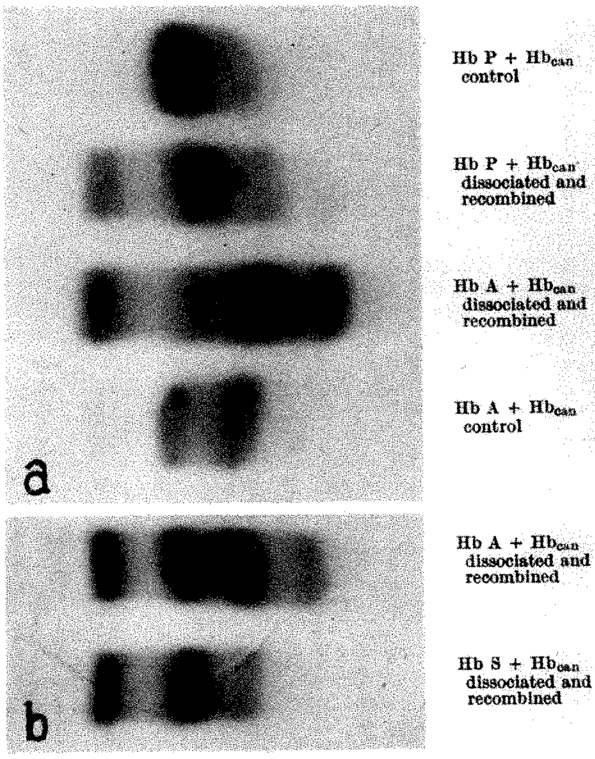
Fig. 5. Hybridization of hæmoglobin P with hæmoglobin L$_{\text{Ferrara}}$ and with hæmoglobin S. Discontinuous buffer system, pH 8·2, ionic strength 0·06, o-dianisidine stain. The hybridization of hæmoglobin P with hæmoglobin L$_{\text{Ferrara}}$ produces two new hæmoglobins: hæmoglobin A and a slow hæmoglobin, which are lacking in the hybridization of hæmoglobin P with hæmoglobin S

Presence of Altered β-Chain in Hæmoglobin P

On the hæmoglobin P of the members of the Italian family, originating from Calabria, previously illustrated[5,6], experiments of hybridization have been conducted with the micromethod of Gammack *et al.*[3], for the purpose of identifying the abnormal chain. No new electrophoretic species were detected in hybridization of hæmoglobin P with hæmoglobin S (Fig. 5), but hybridization with hæmoglobin L$_{\text{Ferrara}}$ (which has an abnormal α-chain[4]) produced a new hæmoglobin species which migrates slower than hæmoglobin L and hæmoglobin P, and a very clear hæmoglobin fraction which migrates in the position of hæmoglobin A (Fig. 5).

These results are sufficient to show that the present hæmoglobin P has an abnormal β-chain. The fact is also confirmed by hybridization with canine hæmoglobin (Fig. 6), which produces only a new hæmoglobin species in the position of fraction $\alpha_2^A\beta_2^{can}$, while, as in the hybridization of hæmoglobin S with canine hæmoglobin (Fig. 6), the hæmoglobin fraction corresponding to the hybrid $\alpha_2^{can}\beta_2^A$ is completely lacking.



Hb P + Hb$_{can}$ control
Hb P + Hb$_{can}$ dissociated and recombined
Hb A + Hb$_{can}$ dissociated and recombined
Hb A + Hb$_{can}$ control
a
Hb A + Hb$_{can}$ dissociated and recombined
Hb S + Hb$_{can}$ dissociated and recombined
b

Fig. 6. *a*, Hybridization of hæmoglobin P with canine hæmoglobin, compared with hybridization of hæmoglobin A with canine hæmoglobin; *b*, hybridization of hæmoglobin A with canine hæmoglobin, compared with hybridization of hæmoglobin S with canine hæmoglobin. The slow hæmoglobin which appears from the hybridization of hæmoglobin P with canine hæmoglobin is identical to the slow hæmoglobin which appears from the hybridization of hæmoglobin S with canine hæmoglobin and to the hybrid $\alpha_2^A\beta_2^{can}$

The hæmoglobin P observed in Italy thus appears altered in the β-chain, as the hæmoglobin P observed by Dherte *et al.*[7] in Belgian Congo Negroes and analysed by Gammack *et al.*[3].

A PHEROMONE FOR MELANIZATION OF LOCUSTS

By DR. D. J. NOLTE

Department of Zoology, University of the Witwatersrand, Johannesburg

THE theory of phase transformation of locusts, promulgated by Uvarov[1] in 1921, was placed on a firm basis by Faure[2], who demonstrated phase transformation and colour change in the four principal species of locusts of Africa. Characteristic of such change from the green or buff or fawn 'grasshopper' or solitaria phase is the melanization of the immature hopper stages or instars. This process is reversible during the instar stages on drastic reduction of population density. In the extreme gregaria phase the hoppers of *Schistocerca gregaria* Forsk., the desert locust, are almost totally black; hoppers of *Locusta migratoria migratorioides* R. and F., the tropical migratory locust, have the dorsal half of the body black; hoppers of *Locustana pardalina* Walk., the brown locust, are black laterally. In gregaria hoppers melanin constitutes the pattern pigment while background pigmentation is due mainly to tanned proteins, carotenoids and ommochrome, brownish, yellow and brown to red respectively.

In solitarization experiments in our Locust Research Unit, *Locusta* and *Locustana* hoppers of the second and third instars have been found to transform fairly readily to the green or fawn solitaria colours during later instars when kept in isolation in quart jars. During the past winter a biochemistry student had occasion to attempt such transformation for *Schistocerca* but produced only black succeeding instars with few exceptions. This phenomenon was also observed in a selection experiment for differences in colour transformation in strains of *Locusta* during the same period, whereas earlier in the year loss of melanin had been quite rapid. Since during the winter season the locust laboratory is rather poorly ventilated in order to attain the rather high temperatures required for locust breeding, it seemed as if the air of this room, which contains about 70 cages with the three species under crowded conditions, could be a contributory cause of retention of black coloration. An experiment was accordingly set up to test this hypothesis with the genetics laboratory as control room. This room houses *Drosophila* stocks and is also rather poorly ventilated during winter. The tests were run as three consecutive experiments.

In the first experiment, a series of ten isolated late second instar hoppers from each of crowded cages of *Schistocerca* and *Locustana*, thus with the characteristic black gregaria coloration, was placed in each of the laboratories. In the second experiment two hoppers were placed in each of five jars for the three species *Schistocerca*, *Locustana* and *Locusta* and duplicates housed in the two laboratories; for the first two species the hoppers were from different strains to those of the first experiment. *Locusta* was tested only in the pairs experiment since this species has been found to solitarize fairly readily in single cultures; for *Locustana*, females only were used since in the field males turn green much more rarely than females.

In the third experiment ten black hoppers of *Schistocerca* were isolated during early third instar and housed in the genetics laboratory. Immediately after the third moult the first three individuals which had turned fawn in colour were returned to the locust laboratory and placed slightly below the level of the crowded cage from which they had been obtained. For another three hoppers which turned fawn in colour at the third moult, the bottom of the jars were lined with strips torn from recently used filters of respirators worn as protection for workers in the locust laboratory against the allergenic substance which seems to be prevalent in locust laboratories; a strip of such a filter was also suspended in each jar for the hopper to roost on. These jars remained in the genetics laboratory where the other four hoppers were also retained as controls.

In all three experiments the quart jars were covered with gauze wire lids and the hoppers were kept constantly supplied with fresh green grass in tubes of water. The jars of a series were placed in a circle around a 40-W lamp and were separated from each other by cardboard partitions. Temperature and humidity conditions were kept as closely similar as possible in the two laboratories. For example, during the course of the first experiment the temperature range in the locust laboratory was 24°–31° C and the humidity range was 25–35 per cent, while for the genetics laboratory the ranges were 24°–30° C and 23–32 per cent; for the second experiment the ranges were 24°–32° C and 32–40 per cent for the locust laboratory and 23°–30° C and 30–40 per cent for the genetics laboratory.

Some fifth instar hoppers died during the final moult, but the adults which were obtained were measured for length of elytron (E), length of hind femur (F) and width of head (C) since from these data the most useful morphometric ratios differentiating the two phases may be calculated, namely, E/F and F/C.

The results obtained in the three series of experiments are given in Tables 1–3.

* Greater amount of black than in those of the same class in other laboratory.

Phase transformation in locusts is a process resulting in changes in behaviour, morphology, physiology and the biochemical processes of pigmentation. To a large extent, this transformation is dependent on density and is reversible in the immature stages or instars. Gregaria hoppers are more active, eat more, produce the typical melanin coloration, and in the adult the wings are relatively longer, that is, the morphometric ratio E/F is higher than in solitaria, while the head is broader so that the ratio F/C is smaller than in solitaria. The characteristic colour of hoppers of the solitaria phase is green, or varies from grey to buff or fawn. In the series of experiments described, there is quite clearly an external factor influencing loss of black pigmentation in hoppers reared under solitary conditions. Since the only variable factor

in the two breeding rooms appears to be the air it has to be postulated that some air-borne factor is affecting the rate of deposition of melanin in the cuticle This role could be filled by a pheromone, which Karlson and Butenandt[5] have defined as a substance secreted to the outside of the individual and received by a second individual of the same species in which it releases a specific action, for example, a definite behaviour or developmental process Whether this substance is species-specific is not evident in the present series of experiments since all three species are well represented in numbers in the locust laboratory, since the cages have gauze wire sides any volatile substance could diffuse readily There are, however, indications that the three species differ in their receptivity to the pheromone since, in the pairs experiment especially, *Schistocerca* was influenced to a greater extent than the other two species of which *Locusta* was perhaps slightly the more sensitive

The pairs experiment shows that once the gregarization process has been initiated, and thus the substance is being produced, it exerts a cumulative action so that even two individuals mutually affect each other Again, however, the locust room had a greater effect The pheromone discovered by Loher[6] in *Schistocerca* is probably of a different nature since it seems to exert only an accelerating influence on sexual maturity

It was thought that some connexion might exist between the postulated pheromone and the allergenic substance found in locust breeding rooms and which affects the mucous membranes of workers The results of the experiment in which the hoppers had continuous contact with the used respirator filter are, however, not conclusive since the substance may be fairly volatile and may dissipate easily

The recorded experiments have also demonstrated that the processes of melanization and production of green pigmentation are independent since hoppers under isolation may or may not build up green pigment while large amounts of melanin are still present Gunn and Hunter-Jones[7] have by means of divergent selection experiments for the *E*/*F* ratio been able to separate characters used in biometric estimates of phase status from each other and to some extent from colour The present series of experiments appears to demonstrate the fact that in a congregating group of hoppers the melanization process is triggered by the cumulation of pheromone in the atmosphere around the group To what extent this stimulation has a direct influence on morphometrical ratios is not quite clear. As shown in Table 3, the various treatments are not based on sufficient individuals to be statistically significant, and, in any case, all individuals spent part of their formative instar life in the gregaria phase In addition these ratios are most often not as extreme for cage-bred as for field populations In the case of *Locustana*, solitarization in both rooms has produced morphometric ratios of a more gregarious type in experiment 1 and of a more solitary type in experiment 2 For *Locusta* the figures are more or less equivalent for the two treatments and are of a more intermediate value. For these two species the grade of melanization seems to be an element separable from phase morphometrics For *Schistocerca*, however, it has lately been found in the Locust Research Unit that the *E*/*F* ratio of cage-bred populations is higher than the data given for swarms in the field[3] Furthermore, the results of Table 3 are indicative of more gregaria-like ratios in the individuals which were returned to the locust laboratory and which re-acquired darker coloration

Table 3 Morphometric Ratios of Adults obtained in the Three Experiments compared with Crowded Cages and Field Material

Species	Exp	Laboratory	Female		Male	
			E/*F*	*F*/*C*	*E*/*F*	*F*/*C*
Locustana	1 2	Locust	2 12	2 79

		Cage	2 35	3 32	2 30	3 29
		Field solitaria (ref 3)	2 07	3 93	2 04	3 86
		Field gregaria (ref 3)	2 29	3 18	2 24	3 11
Locusta	2 3	Locust	1 86	3 35	1 94	3 35
		Genetics	1 85	3 32	1 91	3 46
		Cage	2 00	3 17	1 96	3 21
		Field solitaria (ref 4)	1 81	3 46	1 78	3 67
		Field gregaria (ref 4)	2 18	2 86	2 13	2 96

Finally, it is suggested that the postulated pheromone could possibly be accumulated in the eggs of gregarious females, and in this sense it replaces the locustine suggested by Faure[2], this substance was supposed to accumulate in such eggs and give rise to the dark hatchlings produced by crowded females as compared with the light hatchlings from solitary females

ABSENCE OF RIBONUCLEASE FROM THE RIBOSOMES OF *PSEUDOMONAS FLUORESCENS*

By H E WADE and H. K. ROBINSON

Microbiological Research Establishment, Porton, Salisbury, Wilts.

A CHARACTERISTIC of ribosomes is an instability towards ethylenediamine tetraacetate (EDTA)[1-3] which frequently terminates in the depolymerization of the ribonucleic acid (RNA)[4-6] This general observation, and the prominence given to an EDTA-activated ribonuclease which is associated with ribosomes from *Escherichia coli*[5-7], have led to the impression that a ribonuclease similar to pancreatic ribonuclease is associated with ribosomes from every source[2,6,8]. This impression has been fostered by the exclusive location of ribonuclease in the '30*S*' ribosomes of *E. coli*[6] and the observation that the ribonuclease content of living cells, in general, appears to vary like the concentration of ribosomes, with the rates of growth or protein synthesis[9].

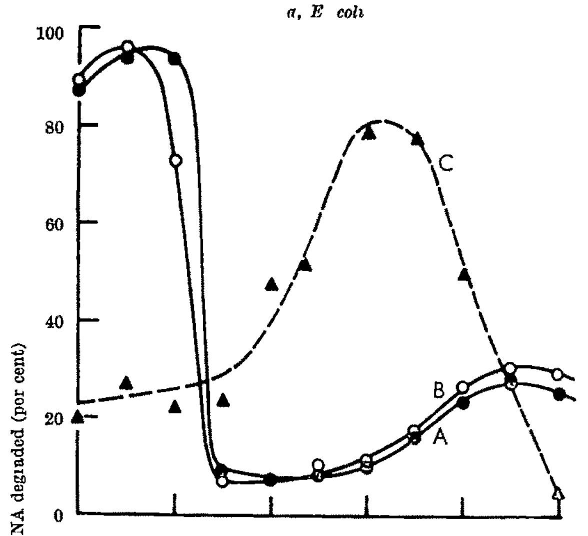
In the course of examining the ribosomes from other species of bacteria, it was found that the processes of ribosome autodegradation did not conform to a common pattern. In particular, ribosomes from *E. coli* and *Pseudomonas fluorescens* were markedly different, reflecting differences in their nuclease contents.

Escherichia coli, American type *B* (*E. coli, B*) was grown (division time 50 min) aerobically in a mineral salts–glucose–ammonium medium by continuous culture[5]. *Pseudomonas fluorescens* (N.C.T.C. 8248) was grown (division time 55 min) in a similar medium supplemented with glutamate.

The bacteria were disrupted in a press[10], suspended (10 per cent wet weight) in 0.145 M sodium chloride with 5 mM magnesium chloride at *p*H 6.5 (*SM* soln.) and centrifuged at 25,000*g* for 1 h at 2°–4° in the No. 30 rotor of the Spinco model *L* centrifuge to sediment heavy particulate material. The supernatant was centrifuged at 85,000*g* for 7.5 h at 2°–4° to sediment ribosomes. The ribosome pellets were inclined at an angle of 45° to allow loose gelatinous material on the surface to fall away, this material was transferred to the final supernatant fraction. The ribosomes were washed twice with 20 volumes of *SM* soln. and stored under toluene at 2°–4°.

The determinations of protein[11], RNA[12] and deoxyribonucleic acid (DNA)[13] showed that the distributions of these constituents between the fractions were very similar in the two species (Table 1). The ribosomes from *Ps. fluorescens*, however, had a greater proportion of protein to RNA than those from *E. coli, B*.

a, E. coli



b Ps. fluorescens

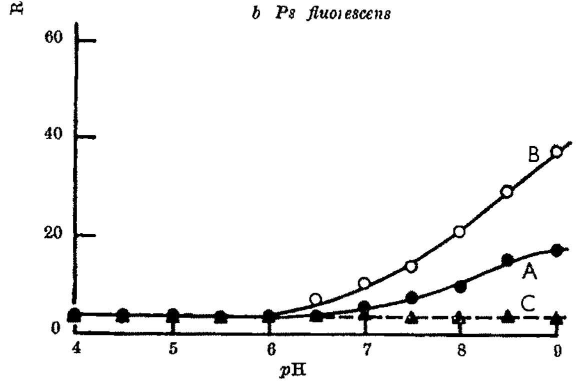


Fig. 1. The autodegradation of ribosomes from (*a*) *E. coli, B* and (*b*) *Ps. fluorescens* in 0.15 M Roth buffers in the presence of (*A*) mM Mg²⁺ (●), (*B*) mM Mg²⁺ and 10 mM orthophosphate (○), or (*C*) 20 mM EDTA (▲). Suspensions of ribosomes were incubated at 37° and samples taken at 2 h (*A* and *B*) or 10 min (*C*)

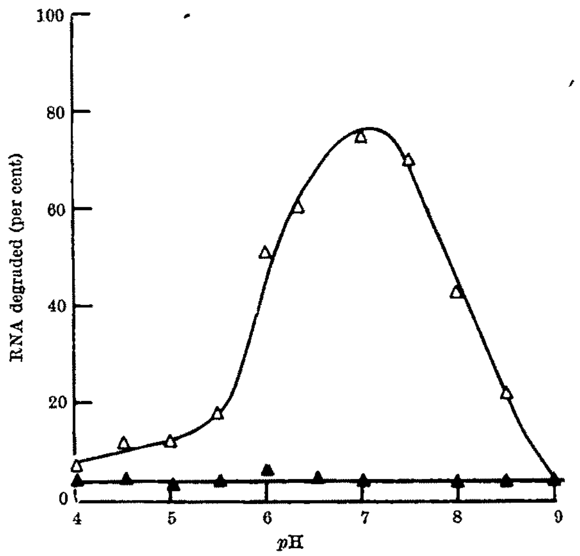

Fig. 2. The autodegradation of ribosomes in disrupted cells of *E. coli, B* (△), and *Ps. fluorescens* (▲). Suspensions were incubated at 37° in 0.15 M Roth buffers in the presence of 20 mM EDTA and samples were taken at 10 min (*E. coli, B*) or 6 h (*Ps. fluorescens*)

The ribosomes were suspended (20 mg dry wt./ml.) in *SM* soln. at 2°–4° and diluted with (*a*) 4 vol. of 0.15 M Roth buffer[14], (*b*) 4 vol. of 0.15 M Roth buffer containing 12.5 mM sodium orthophosphate, or (*c*) 2.32 vol. of 0.15 M Roth buffer containing 28.5 mM EDTA. The buffers were adjusted to values between *p*H 4 and *p*H 9 at intervals of 0.5. The diluted ribosome suspensions (0.5 ml.) were incubated at 37° and samples were extracted with 0.1 N perchloric acid at regular intervals to determine the extent of RNA degradation[5]. The results revealed differences between the ribosomes from *E. coli, B* (Fig. 1*a*), and *Ps. fluorescens* (Fig. 1*b*).

In the presence of mM magnesium chloride, there was rapid breakdown of RNA at *p*H 4–5 in *E. coli, B*, but none in *Ps. fluorescens* (Figs. 1*A* and *B*). Above *p*H 7.5 the rates of breakdown were similar in the absence of orthophosphate (Fig. 1*A*) but, in its presence (Fig. 1*B*), the breakdown was stimulated to a greater extent in *Ps. fluorescens* than in *E. coli, B*. This suggests that ribosomes from the *Pseudomonas* have a higher content of polynucleotide phosphorylase[15]. In this respect, *Ps. fluorescens* more closely resembles *E. coli* N.C.T.C. 1100 (ref. 15).

In the presence of 20 mM EDTA, the differences between *E. coli, B*, and *Ps. fluorescens* were very marked (Fig. 1,*C*). The ribosomal ribonuclease revealed by this treatment was very prominent in *E. coli, B*, and undetectable in *Ps. fluorescens* even after continued incubation for 2 h. The degradation at *p*H 4–5 observed in the presence of mM magnesium chloride (Fig. 1*a*, *A* and *B*) could also be attributed to the ribonuclease since an alkali degradation of the primary acid-soluble products, produced only nucleoside 2′(3′)-phosphates, which were identified by

Table 1. DISTRIBUTION OF NUCLEIC ACIDS AND PROTEIN BETWEEN SEDIMENTATION FRACTIONS FROM *Escherichia coli, B*, AND *Pseudomonas fluorescens*

Fraction		*E. coli, B*	*Ps. fluorescens*
Heavy particulate	Protein	4.77	5.3
	RNA	0.86	0.66
	DNA	0.19	0.15
Ribosome	Protein	1.78	2.25
	RNA	2.20	2.38
	DNA	0.001	0.005
Soluble	Protein	8.4	7.4
	RNA	0.98	1.00
	DNA	0.50	0.54

The results are expressed as mg/ml. of initial, unfractionated suspension of disrupted bacteria their elution pattern from ion-exchange resin[16] and their resistance to periodate[17].

Although ribonuclease appears to be located exclusively in the ribosome fraction of *E. coli*[6], this did not preclude the possibility that, in *Ps. fluorescens*, the enzyme is present in some other fraction of the cell. To examine this point, a suspension of unfractionated disrupted bacteria was incubated with 20 mM EDTA between *p*H 4 and *p*H 9 (Fig. 2). In *E. coli, B*, the RNA was broken down at about the same rate as in the isolated ribosome fraction; in *Ps. fluorescens* there was no significant breakdown even after incubation for 6 h, suggesting the absence of the enzyme from this species.

The inability to detect ribonuclease in *Ps. fluorescens* may have a simple explanation. It is possible that the enzyme is present but tightly bound to an inhibitor and that, in other circumstances, it would have been detected. If the enzyme is in fact absent, its absence may reflect some feature of growth rather than a genetic inability to synthesize the enzyme. Whatever the explanation, the ribosomes from *Ps. fluorescens* more closely resemble certain ribosome preparations from higher cells in having negligible ribonuclease activity; in these preparations the ribosomes are not degraded by EDTA beyond smaller sedimentable particles[2,3,18-22]. Sedimentation analyses were carried out to determine whether or not similar changes could be observed with ribosomes from *Ps. fluorescens*.

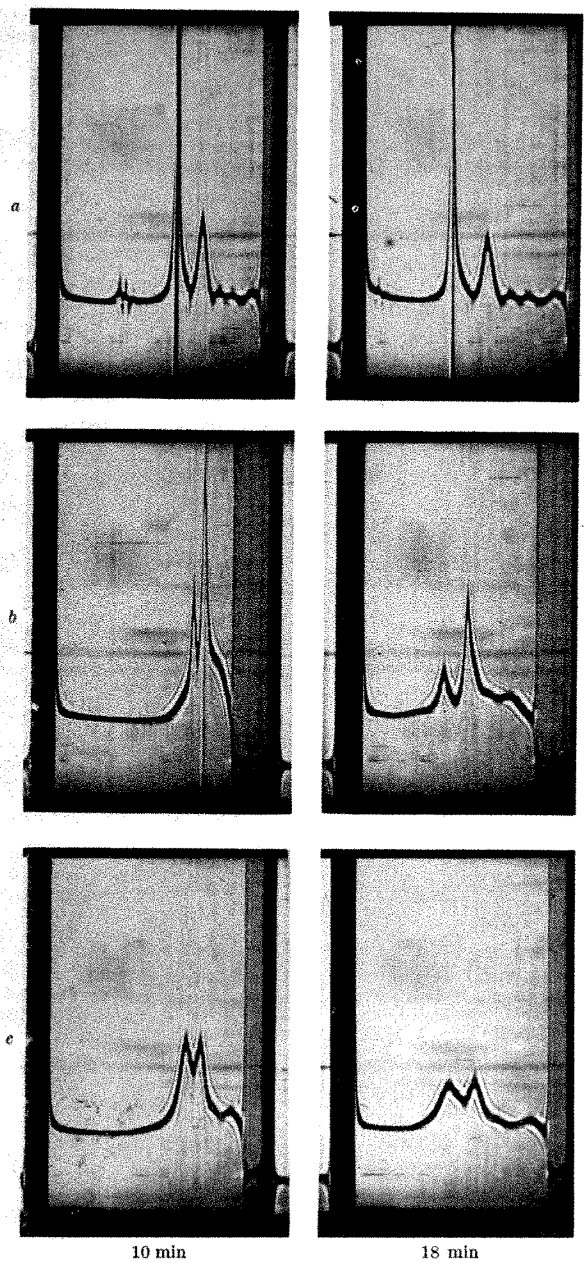

Fig. 3. The sedimentation analysis of ribosomes from *Ps. fluorescens*. (*a*) A suspension (12 mg dry weight/ml.) in 0·145 M NaCl with 5 mM $MgCl_2$ at *p*H 6·5; (*b*) after dialysing for two days against 0·145 M NaCl with mM EDTA; (*c*) after dialysing for two days against 0·145 M NaCl with mM EDTA and two days against 0·145 M NaCl with 5 mM $MgCl_2$. Photographs were taken at 10 min and 18 min after reaching full speed (47,660 r.p.m.) at 25° (R.T.I.C. unit); phase angle 55°

A suspension of ribosomes in *SM* soln. gave a typical sedimentation pattern in the analytical centrifuge (Spinco model *E*), with a major 45·4*S* (S_{w20}) peak and a minor 31·9*S* peak, corresponding to the '50*S*' and '30*S*' ribosomes[23] respectively, and also traces of a '70*S*' and two slow sedimenting peaks (Fig. 3*a*). When this suspension was dialysed against 0·145 M sodium chloride with mM EDTA at *p*H 6, conditions under which the RNA in *E. coli* ribosomes breaks down into acid-soluble substances, dissociation into more slowly sedimenting components occurred with major peaks at 15·4*S* and 20·3*S* (Fig. 3*b*). When the reversibility of these changes was tested by dialysing back into *SM* soln., non-specific aggregation occurred with the formation of peaks at 23·1*S* and 31·2*S* (Fig. 3*c*), similar to the aggregation which occurs with EDTA-treated ribosomes from higher cells[18,19].

As in other ribosome preparations which exhibit negligible ribonuclease activity, the ribosomes from *Ps. fluorescens* produce two, more slowly sedimenting components when exposed to EDTA. In pea seedlings[18], thymus nuclei[20], rat liver microsomes[19] and Novikoff hepatoma[22], these components sediment at 23–30*S* and 40–46*S*, the heavier component being about twice the concentration of the ligher component. In contrast to this, the two most prominent components from *Ps. fluorescens* sediment more slowly (15·4*S* and 20·3*S*) and the lighter one is the more prominent (Fig. 3*b*) suggesting that the untreated ribosomes react differently towards EDTA. It is tempting to speculate, from the sedimentation coefficients and the relative concentrations, that in *Ps. fluorescens* these components are ribosomal RNA[23]; however, there is at present no other experimental evidence to support this.

We thank Mr. K. H. Grinstead for carrying out the sedimentation analyses and Dr. K. A. Cammack for his advice.

INSECTICIDE RESISTANCE IN THE CABBAGE ROOT FLY IN BRITAIN

By T. H. COAKER, D. J. MOWAT and G. A. WHEATLEY

National Vegetable Research Station, Wellesbourne, Warwick

ALDRIN and dieldrin are the principal insecticides used in Britain to control the cabbage root fly (*Erioischia brassicae* (Bouché)) attacking brassica crops. If the recommended methods for using these insecticides are followed, that is, a root dip for transplants or treatment of the soil around the plants after transplanting, the amount of active ingredient applied does not usually exceed 0·4 lb. per acre and this is adequate to give a high degree of control[1]. There is no evidence that resistance to these insecticides has developed in Britain when these recommendations have been followed.

Early in June 1963, a case of a failure to control this pest with aldrin was brought to our notice. On a farm near Great Rollright, Oxfordshire, the infestation by the first generation of the root fly was very severe with up to 50 or more larvæ present on many of the plant root systems. About 140 acres of the early brussels sprout crop were destroyed and several more acres were severely damaged, despite the copious use of aldrin as a broadcast treatment to the soil before transplanting and also as a spot treatment after planting out; either treatment by itself is normally sufficient to effect control. Furthermore, enquiries revealed that most fields on the farm had been intensively cropped with brassicas (at least five crops of cauliflowers or brussels sprouts in eight years) and that both broadcast and spot treatments with aldrin had been used on each crop. The brassica crop on this farm was relatively isolated from those on neighbouring farms, and a consideration of these factors suggested that the root fly population on this farm was local and had developed resistance to aldrin.

In order to confirm that large amounts of aldrin had been used in the past, soil samples were obtained from one field where the crop had been destroyed by the root fly. Two samples were taken from the inter-plant spaces and a further two samples from within about 5 cm of the plant stems in the region which would normally have been spot-treated. Each sample comprised 25 cores × 2·59 mm diam.; those from the interplant spaces were taken to the maximum estimated depth of cultivation (22 cm), while those from near the plants were restricted to 15 cm in depth. The samples were thoroughly mixed and sub-samples were taken and kept at $-8°$ C prior to analysis. 50 g of soil was extracted with hot acetone and, after suitable clean-up, the extracts were transferred to *n*-hexane, concentrated and made up to 5 ml. Aliquots of the extracts were analysed qualitatively and quantitatively by reversed phase paper partition chromatography[2], the identities of the residue components being confirmed by gas/liquid chromatography using an electron capture detector. The results in Table 1 show that there was indeed a high concentration of aldrin in the soil next to the plant roots at the time when large numbers of root fly larvæ were present. Aldrin was also present in the soil taken from between the plants and there was a high general level of dieldrin in both types of sample, the dieldrin having been formed by epoxidation of aldrin used on previous crops. DDT was known to have been used occasionally to control certain foliage pests, and the several components of technical DDT, and the degradation product DDE, were detected in the samples, thus confirming previous observations that foliage treatments with this insecticide lead to appreciable residues in the soil[2].

Table 1. RESIDUES IN SOIL SAMPLES TAKEN ON JUNE 13, 1963; ASSESSED BY PAPER CHROMATOGRAPHY

Means of duplicate measurements on duplicate samples

Insecticide	Position of sample			
	Near plant stem		Inter-plant space	
	p.p.m.	lb./acre	p.p.m.	lb./acre
Aldrin	13	20	0·70	1·7
Dieldrin	1·8	2·7	0·82	2·0
p,p'-DDT	—	—	0·77	1·8
o,p'-DDT	—	—	0·16	0·38
DDE	—	—	0·28	0·68
DDD	Small amount detected—not measured			
γ-BHC	—	—	< 0·008	< 0·018
Standard error (%)	± 19·0	± 18·9	± 5·6	± 5·4

Table 2. RESIDUES IN SOIL SAMPLES TAKEN AUGUST 20, 1963, AFTER THE FIELD HAD BEEN CULTIVATED

Means of duplicate measurements on four samples

Insecticide	Chromatographic system			
	Paper partition		Gas/liquid	
	p.p.m.	lb./acre	p.p.m.	lb./acre
Aldrin	0·75	1·7	0·71	1·6
Dieldrin	0·72	1·7	0·58	1·3
p,p'-DDT	0·74	1·7	0·56	1·3
o,p'-DDT	0·15	0·35	0·13	0·29
DDE	0·22	0·51	0·13	0·29
DDD	Small amounts detected—not measured			
γ-BHC	< 0·008	< 0·018	0·004	0·009
Standard error (%)	± 15·2	± 15·0	± 13·1	± 13·1

The remains of the crop were afterwards destroyed and four further soil samples were obtained from the same field on August 20, 1963, after the soil had been cultivated. The residues were assessed by paper and gas/liquid chromatography, and the results (Table 2) from the two methods are mutually confirmatory. The levels of residues found were similar to those in the inter-plant soil samples taken in June.

Laboratory tests. The susceptibility to dieldrin of adult cabbage root flies obtained from pupæ collected at Great Rollright was compared with that of flies collected similarly from a field population at Wellesbourne. The root fly population at Wellesbourne is still readily controlled by normal applications of aldrin and dieldrin although these insecticides have been regularly used during the past ten years.

Batches of flies comprising equal numbers of newly emerged males and females were used for the tests. They were anæsthetized with nitrogen, and technical dieldrin dissolved in Shell 'Risella 17' oil was applied to the coxal region after which the flies were allowed to recover and were held at 18° C during the tests. The mortalities were assessed at suitable intervals and the time/response curves constructed, their average slopes being 0·98 and 1·40 for the Rollright and Wellesbourne strains respectively. From the relationship, dose versus time, taken for 50 per cent response (T_{50}, Fig. 1) derived from the time/

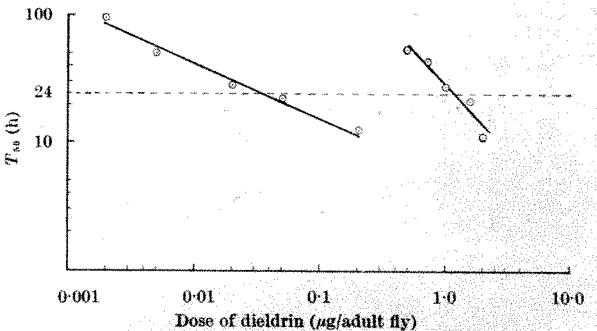

Fig. 1. Relationship of time taken for a 50 per cent response with several doses of dieldrin for Wellesbourne and Rollright strains of adult *E. brassicae*

Table 3 DEGREE OF CONTROL OF THE CABBAGE ROOT FLY POPULATION AT ROLLRIGHT BY SPOT TREATMENTS OF INSECTICIDES

	Active ingredient (per cent)	No larvæ and pupæ/10 plants	Root damage index (per cent)
Dieldrin	0 03	146	68
Dieldrin	0 15	141	63
Dieldrin	0 30	127	51
BHC	0 02	84	41
Diazinon	0 05	22	18
Untreated	—	119	56
	S E (diff)	±19 6	± 7 6
	L S D (*P* = 0 05)	±43 7	±16 9

response curves, 1 23 μg dieldrin per fly was required for 50 per cent response at 24 h for the Rollright strain compared with 0 035 μg dieldrin per fly for the Wellesbourne flies Further tests using aldrin and γ-BHC indicated that the Rollright strain was resistant to these insecticides also

Field tests To test the susceptibility of the larvæ attacking brussels sprout plants at Rollright, drench treatments of three commercially available insecticides (dieldrin, γ-BHC and diazinon) known to control the root fly under normal conditions were applied to young plants on June 26, one week after transplanting Two months later, at the end of the attack by the second generation of the root fly, the plants were sampled and the numbers of larvæ and pupæ and the amount of root damage were assessed (Table 3) Plants treated with dieldrin, even at ten times the amount normally required to kill susceptible larvæ, were as severely damaged as the untreated ones and the numbers of larvæ present were similar Gamma-BHC gave some degree of control, and it was only the organophosphorus insecticide, diazinon, which was highly effective in reducing both the number of larvæ and root damage.

It is also interesting that no parasitism was recorded in a total of about 2,000 pupæ collected from Rollright whereas in the Wellesbourne population 40–60 per cent of the pupæ are normally parasitized by *Aleochara* spp (Col , Staphylinidae) and *Idiomorpha rapae* (Westwood) (Hymen , Cynipidae)

The ability of larvæ of the Rollright strain of root flies to survive in the presence of high concentrations of aldrin and dieldrin in the soil, and the widely differing susceptibilities of the adult flies from Rollright and Wellesbourne to aldrin, dieldrin and γ-BHC, indicated that the former strain of flies had developed resistance to these insecticides This is further confirmed by the satisfactory control obtained in the field by diazinon, a result which also suggests that diazinon may be used as a possible alternative means of controlling root fly which is resistant to the *cyclo*diene-type insecticides

We should like to thank Mr K Coghill for bringing this problem to our attention

POLYDISPERSITY

By R. A GIBBONS

National Institute for Research in Dairying, Shinfield, Reading

IT seems desirable to attempt to clarify the concept of polydispersity in biological macromolecular preparations The term 'polydisperse' has often been used as a synonym for heterogeneous, nevertheless there is a general sense, as a rule, that the former implies a less-impure preparation than the latter It appears to me that there is, or should be, a valid distinction between these two terms which it is useful to maintain

A preparation which is monodisperse with respect to all its properties, that is, homogeneous *sensu strictori*, consists of an assemblage of identical molecules, having the same electrophoretic mobility, frictional coefficient, chemical composition and structure, immunological reactivity, etc The variance of all measurable parameters throughout the sample is zero If this is not so, and one or more parameters show some variability within the sample, two types of variability may be usefully distinguished Where n_i is the number of molecules in the sample possessing amount p_i of a measurable property, p_i may be (1) a unimodal or (2) a bi- or poly-modal function of n_i A preparation in which p_i varies unimodally with n_i for all measurable properties p (that is, the distribution curves have one maximum value and two points of inflexion only) may in most contexts be considered a pure or homogeneous preparation, provided that the variance is not great The molecules in such a sample constitute statistically a single population, and this should be the criterion of a polydisperse preparation Where the variability of any parameter can be shown to be bi- or poly-modal, the preparation should be characterized as heterogeneous

In this way a preparation containing molecules which are all the same type, but which vary only in chain-length or in some other structural detail, is distinguished from a mixture of two different molecular species Thus pure samples of chondroitin sulphates *A* and *B* would each be homogeneous but polydisperse (with respect to chain-length), but a mixture of the two would be heterogeneous even if the molecular weight distributions for each component happened to be the same, for the distribution of other parameters (amount of glucuronic acid per molecule, optical rotation) would be bimodal Clearly, a preparation may be monodisperse with respect to one parameter, polydisperse with respect to a second and heterogeneous with respect to a third, the foregoing terms are only meaningful if the parameter measured is implicitly or explicitly specified

It is assumed here that biological macromolecules may be produced having the type of variability in physical and chemical properties which may be approximated to a continuous distribution, as for example the chain-length of a synthetic polymer This assumption is not compatible with present-day views on the very high degree of precision with which proteins are synthesized[1], but there is no reason to believe that all macromolecules, or even all proteins, arise by primary gene-directed synthesis. Proteins are indeed something of a special case among naturally occurring macromolecules in that the primary structure is specified by the gene DNA, and any variability is limited to the loss of information in transmission between gene and microsome Present evidence suggests this is slight[2] Genetically determined variants of what is functionally the same protein exist in some profusion[3]

Where a protein is made up of a number of sub-units, themselves polymorphic in the genetic sense, the number of distinguishable 'isoproteins' may be quite large, even in one individual In these circumstances, it may sometimes be convenient to regard the material as polydisperse in the sense defined with respect to some of its properties, for example, sedimentation coefficient or electrophoretic mobility Even so, this type of variability is generally likely to lack sufficient of the random element for any molecular parameter to be usefully considered as continuously variable, but it has been suggested that some degree of random variability in secondary or tertiary structure may confer polydispersity with respect to frictional coefficient on some proteins[4] The position is otherwise with regard to substances the synthesis of which is not directly gene-controlled Genetic control is exercised here only in the sense that the gene (or genes) produces an enzyme which participates in the biosynthetic system Glycogen is a well-studied macromolecule which is known to be produced in this way[5] At least two enzymes, themselves the products of different genes, are involved co-operatively in its synthesis, and, while these enzymes are quite specific in the type of chemical linkage which they introduce, the length of the poly-glucoside chains and the precise position of the 1→6 branch points are subject to a limited amount of random variability[5,6]

Thus, glycogen is not a unique chemical individual, any preparation contains molecules which vary both in molecular weight and in detailed chemical structure Another material which is similarly produced is the human blood-group substance This may seem surprising since the simple Mendelian inheritance of the blood-group characteristic suggests a close relation of the blood-group substance and the gene, but this is not so The ABO blood-group antibodies react with rather small specific oligosaccharide groupings[7] which are introduced quite late in the synthesis of the macromolecule[8] The enzymes which effect this introduction are themselves presumably the products of the blood-group genes. The blood-group substance molecule, as present in mucous secretions, is the product of many genes, and the evidence suggests that, like glycogen, there is considerable natural variation in the size and structural detail of these substances[9] It is likely that many macromolecular substances, particularly when they are largely or entirely non-protein in character, arise in this way Thus epithelial mucus contains a number of mucosubstances chemically similar to the blood-group substances[10], and their biosynthesis is unlikely to be radically different The composition of one of these substances varies with the hormonal state of the animal[11], this indicates that polydispersity with respect to one aspect of the structure of this molecule (amount of terminal neuraminic acid present) is of biosynthetic origin Some proteins may likewise be modified by other gene products before reaching their final functional state[12] In very large molecules, the extent of variability arising from a quite small degree of imprecision in biosynthesis may be very great—for example the number of theoretically distinguishable glycogen molecules of molecular weight 10^7 is greater than 10^{2000} A sample of this polysaccharide can never be other than polydisperse, but a pure or homogeneous preparation of glycogen is nevertheless a meaningful concept This is the justification for the distinction between 'heterogeneous' and 'polydisperse' which is proposed

It is necessary to reconsider the customary criteria of homogeneity to distinguish criteria of homogeneity from criteria of monodispersity Thus the observation of a single boundary in a sedimentation velocity or electrophoretic experiment is evidence of homogeneity within the limits of sensitivity of the optical system, the more rigorous ultracentrifugal test of Creeth[13] or electrophoretic test of Alberty[14] distinguish monodisperse from polydisperse materials Furthermore, it is desirable to characterize a preparation which is polydisperse with respect to any given property by the variance of this property (or better its distribution function) in addition to its mean value This is now possible, under favourable conditions, for sedimentation coefficients[15] and electrophoretic mobilities[16]

It is always theoretically possible to subfractionate a polydisperse material Where this is also possible in practice, the subfractions may, indeed should, be distinguishable chemically This is to be interpreted as evidence of polydispersity rather than, necessarily, of inhomogeneity Furthermore, if the naturally occurring material is considerably polydisperse, small variations in isolative procedure will select a slightly different assemblage from an initially polydisperse starting material Different preparations of what is allegedly the same substance will then show small but significant physical chemical and possibly biological differences from one to another, a circumstance which has caused confusion The blood-group substances and the submaxillary mucoproteins would appear to be instances where this has occurred

In considering the properties of a polydisperse assemblage to be continuously variable it has been tacitly assumed that the quantities of all variable properties considered, when expressed as amount per molecule, are large This is tantamount to considering only high-molecular-weight material Where relatively small macromolecules are concerned, it is necessary to take into account the fact that all differences between molecules are ultimately discrete differences It may then be better to represent the distribution as a discontinuous histogram rather than a smooth curve, for it may prove possible to separate adjacent members of a polydisperse assemblage into discrete subfractions A recent examination of human α_1-glycoprotein suggests that this has been achieved in this instance[17] In an extreme case, such as that of ovalbumin, which may have none, one or two phosphate residues only per molecule[18], the statistical concept of molecular variability outlined here is no longer helpful

Molecular variability has been discussed at length by a number of authors[19] It is submitted that confusion has arisen because it has been tacitly assumed in many cases that the system which is now being revealed as responsible for the primary DNA-directed synthesis of proteins (or sub-units of proteins) is the only important biosynthetic mechanism for macromolecular substances This is clearly not true for a number of polysaccharides and glycoproteins, and may not be true of all proteins The distinction between primary and secondary gene-products is a useful one, though probably not absolute, thus the protein portion of a glycoprotein may be a primary gene product whereas the saccharide portion may not be

When the substance under investigation is a protein which is believed to be directly derived from the gene or genes which control its synthesis, it may be justifiable to regard evidence of polydispersity as indicating the presence of either impurities or degradation products This view has, however, served to obscure a distinction which assumes some importance when biosynthesis is not directly gene-controlled and consequently the material being examined does not necessarily consist of an assemblage of identical replicates

PHYSICS

Ultra-violet Gas Laser at Room Temperature

ULTRA-VIOLET coherent light has been generated directly at room temperature in a pulsed nitrogen-gas laser A group of 20 strong simultaneous lines have been observed in the ultra-violet Thirty lines have been identified These range in the ultra-violet spectrum from 3000 Å to 4000 Å The strongest line has been observed at 3371 Å, the strongest visible line is at 3400 Å The output radiation is believed to be produced as the result of inversion in the triplet state of nitrogen, resulting in subsequent emission in the second positive group, $C^3\pi_u \rightarrow B^3\pi_g$ The beam has a full angular width of 1 milliradian, as measured 100 ft from the confocal laser cavity

The plasma is excited with a 100–150-kV pulse of sub-μsec duration The coherent-light pulse width is as short as 20 nsec Despite the short pulse duration the output spot of the laser is exceedingly brilliant The output spot for the confocal Fabry–Perot cavity does not contain the usual mode structure associated with single line operation, a characteristic that is noted when several sets of transitions compete simultaneously

Output powers of the order of 10-W peak have been obtained summing over the lines The plasma tube has a 48-in discharge-length Cold cathode excitation is used The silver-coated flint glass end mirrors are spaced at 150 cm The radius of curvature of the mirrors is approximately 400 cm One mirror is heavily silvered, whereas the other transmits 2 5 per cent

The infra-red nitrogen band spectra[1], which can be produced with 40-kV, 30 amp pulses of 1 μsec duration, are not observed when high-voltage pulses are applied

Exchange Currents at Liquid Electrodes

RATES of non-equilibrium processes cannot be calculated *a priori* without quantitative hypotheses as to energies (heats) of activation I emphasize this truism for electrochemical interface phenomena because ions are field particles in the sense that the potential barrier, over which they pass between the bound state and the solvated state, is itself changed by their passage Only in thermodynamic equilibrium do ions become mere test particles, and it is perhaps for this reason that reversible thermodynamics does not always appear fruitful in this field

In a recent communication[1] a model of the potential barrier, separating ions of a solid metal from solution, has been put forward and compared with known observations I now reconstruct that model for interfaces between liquid metals and polar (aqueous) electrolytes The basis of the model is retained· the height of the potential barrier (activation energy for dissolution) is the corresponding height, V_0, with respect to *vacuo* (the real potential) divided by the dielectric constant, $\varepsilon(\omega)$, of the electrolyte taken at the vibration frequency, ω, of the bound ions in accordance with Debye's theory[2] of the dispersion of the dielectric constant Thus the electrolyte is viewed as a continuous dielectric medium with regard to the weakening of electrostatic interactions, but as a set of molecular dipoles with regard to its temperature-dependent response to the local electrical perturbations caused by the oscillations of ions bound at the interface

The barrier has, therefore, a different height for each vibration frequency, the probability of dissolution per ion and unit time being again[1] $(\omega/2\pi)\exp[-V_0/\varepsilon(\omega)kT]$ We thus need to know the distribution of bound surface ions over frequencies, and for this purpose the specific heat model of Debye[3] has been adapted[1] for solid electrodes Its counterpart for the vibrations of liquid metal surfaces has been given by Frenkel[4], who considered surface capillary waves rather than elastic volume waves and obtained a cut-off frequency by regarding twice the mean particle separation as the shortest admissible wave-length, corresponding to a maximum wave number $K = K_{\max}$ The dispersion of capillary waves is given by

$$\omega_{u} = 2\pi K^{3/2}(\sigma/\rho)^{1/2} \qquad (1)$$

σ being the surface tension and ρ the density of the metal The number of vibration modes per unit surface area (which may be equated to three times the surface concentration of ions, in the manner of Debye[3]) between K and $K + \mathrm{d}K$ is $2\pi K\mathrm{d}K$, so that the absolute dissolution rate is

$$R = \frac{2\pi}{3}\left(\frac{\sigma}{\rho}\right)^{1/2} \int_0^{K_{\max}} \exp[-V_0/\varepsilon(K)kT]K^{5/2}\mathrm{d}K \qquad (2)$$

Wave numbers in the region of $K_{\max}$ correspond by equation (1) to frequencies larger than the inverse Debye relaxation time $1/\tau$ of water molecules At such frequencies the orientational part of the polarizability vanishes and the activation energy becomes prohibitive at room temperatures (about $V_0/3$) It is for this reason that a good first approximation for R is obtained by putting $K_{\max} \sim \infty$ together with $V_0/\varepsilon \approx (V_0/\varepsilon_s)\ (1+\omega^2\tau^2)$, where $\varepsilon_s \approx 80$ is the static dielectric constant of a dilute aqueous solution

$$R \approx \frac{\Gamma(7/6)}{9(2\pi)^{7/3}}\left(\frac{\rho^2}{\tau^7\sigma^2}\right)^{1/3} \frac{\exp(-V_0/\varepsilon_s kT)}{(V_0/\varepsilon_s kT)^{7/6}} \qquad (3)$$

$\Gamma(7/6) \approx 0\ 93$ being a Γ-function The correspondence between equations (2) or (3) and the corresponding expressions for solid metals[1] may be brought out by comparing Frenkel's cut-off frequency with Debye's

When the liquid electrode comes to equilibrium with a solution of its ions, the surface tension σ is connected with the electrode potential according to Lippmann's equation[5] (note that R is the smallest at the potential of the electro-capillary maximum) We may then identify[6] zeR (ze is the ionic charge) with the exchange current density obtained by extrapolating Tafel's overvoltage relations to zero net current[5] It can be shown that Hg^{++} ions are dissolved in monovalent form ($V_0 \approx 6\ 5$ eV from a well-known cycle) and are ionized further by a fast redox step, and if we disregard the slight electrocapillary effect of the Hg^{++} concentration in solution on σ, equation (3) yields some 1 4 amp cm^{-2} at room temperature (not counting the electron current, if we count only one degree of freedom per surface ion, this result is to be multiplied by 3) This agrees with the observation[5] that the exchange current density should exceed 0 4 amp cm^{-2}

On the other hand, from the expression for R of solid metals[1] we obtain for Cu^+ at room temperature the exchange current density of $3\ 8 \times 10^{-5}$ amp cm^{-2} as compared with the observed[5] value 2×10^{-5} amp cm^{-2} Considering the complexity of the physical situation, the calculated values for the liquid as well as the solid electrodes agree well with measurements The two appropriate frequency distributions being very different from each other, the method of constructing the barrier appears to be successful.

Fluorescence Spectrum of Di-cæsium Uranyl Nitrate

IN the course of our investigations on radiation effects on cæsium uranyl nitrate ($CsUO_2(NO_3)_3$) it was found that the spectrum of di-cæsium uranyl nitrate is not known although the spectra of the corresponding di-rubidium and di-potassium uranyl nitrates are known Attempts to prepare di-cæsium uranyl nitrate ($Cs_2UO_2(NO_3)_4$) do not seem to have been successful so far[1] It has, however, been possible to prepare the salt and examine its fluorescence spectrum which is recorded here

If an aqueous solution containing cæsium nitrate and uranyl nitrate hexahydrate in the molar ratio of 2 1, or slightly higher, is allowed to evaporate it is possible to get either mono-cæsium uranyl nitrate or di-cæsium uranyl nitrate by controlling the temperature at which evaporation occurs. Thus at 26° C the crystals which separate out are mostly the well-known pale green crystals of mono-cæsium uranyl nitrate mixed with a few yellowish-green crystals which can be easily picked out from the bulk of the crystals If, however, the evaporation is carried out at 10° C it is found that only the yellowish-green crystals are obtained. Chemical analysis and X-ray diffraction studies of the yellowish-green crystals thus obtained prove conclusively that they are the di-cæsium uranyl nitrate crystals

The fluorescence spectrum of the di-cæsium salt at 77° K which is shown in Fig 1 consists of an extended system of bands The structure of the spectrum as indicated in Fig 1 is in general similar to that of the mono-cæsium salt The symmetric vibration *A* occurs in several quanta (observed up to four) alone and in combination with a single quantum separately of each of the antisymmetric vibration *B*, the bending vibration *C* as well as several of the NO_3 and the so-called lattice frequencies Thus *B*, *C*, NO_3 and the lattice vibrations occur only in single quantum either alone or each in combination with one or several quanta of *A* The *B* band is more intense than *A* and the strongest are *A* + *B*, 2*A* + *B*, 3*A* + *B*, and 4*A* + *B* combination bands The frequencies of vibration of the UO_2^{++} ion are, however, different from those of mono-cæsium uranyl nitrate and as derived from the fluorescence spectrum are 857 2 cm^{-1} (sym *A*), 936 1 cm^{-1} (antisym *B*) and 259 0 cm^{-1} (bending *C*) The resonance band, *R*, is at 20,751 cm^{-1} (4817 7 Å). Certain relevant relations between frequencies of the mono- and di-alkali salts are given in Table 1 The values of vibration frequencies for the various uranyl salts except those of di-cæsium uranyl nitrate are taken from Dieke and Duncan[1]

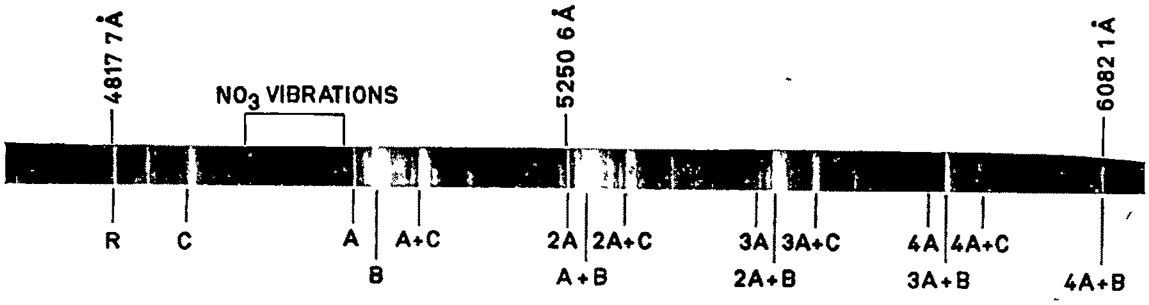

Fig 1

Run-off of Cæsium-137 and Strontium-90 from Rivers

THE factor of weathering must be taken into consideration in the prediction of future radiation dose, either external or internal, caused by the accumulated ground deposits of fission products

Measurements have been made since 1960 on the concentrations of cæsium-137 and strontium-90 in the River Tonegawa, which has the largest catchment area in Japan Monthly deposits of these radionuclides were also measured at Kiriu City, which is situated in the vicinity of the sampling station of river water The results are summarized in Table 1 The concentrations in rain water were calculated by dividing the monthly deposits by the monthly rainfall

An attempt was made to evaluate the run-off of a radionuclide in terms of the cumulative deposition and the deposition rate on the basis of an expression of the following general form

$$C = C_d + p_r C_r$$

where *C* is the concentration of a radionuclide in the river water (μμc./l), C_r is the concentration of the radionuclide in the rain water (μμc /l) corrected for the evaporation (30 per cent is assumed), p_r is a proportionality factor and C_d is the concentration of the radionuclide in the river water which was derived from the cumulative deposition C_d may be assumed to be a function of the cumulative deposition but since its dependence on time during the period of this observation was rather small as compared with that of C_r, it has been temporarily assumed to be constant

Table 1. CONCENTRATIONS OF CÆSIUM-137 AND STRONTIUM-90 IN RIVER- AND RAIN-WATERS (FEBRUARY 1960–JULY 1962)

Time of collection	^{137}Cs $\mu\mu$c./l.		^{90}Sr $\mu\mu$c./l.

July 1962	0·32	15	—	—

* At Kurihashi, River Tonegawa.
† At Kiriu City, Gunma Pref.

Regression analyses by use of the data shown in Table 1 showed the values of p_r for cæsium-137 and strontium-90 as 0·013 and 0·072, respectively. This implies that 1·3 per cent of cæsium-137 and 7·2 per cent of strontium-90 from the land surface which originated from fall-out would be carried by river to the sea. We have also obtained the values of 0·035 and 0·064 $\mu\mu$c./l. for C_d respectively for cæsium-137 and strontium-90; these concentrations indicate the run-off of the cumulative ground deposits as the result of weathering.

To check the geographical variation of these values, which may be recognized between different water sheds, measurements were made on the river waters collected from several localities in Japan during August 1962. The results shown in Table 2 indicate an approximate constancy between different rivers in the concentrations of both cæsium-137 and strontium-90. This suggests the universal validity of the proportionality factors p_r for Japanese rivers.

Table 2. CONCENTRATIONS OF CÆSIUM-137 AND STRONTIUM-90 IN RIVER WATERS IN JAPAN (AUGUST 1962)

River	Day of collection (August)	^{137}Cs ($\mu\mu$c./l.)	^{90}Sr ($\mu\mu$c./l.)
Ōyodogawa	1	0·32	0·19
Shirakawa	3	0·32	0·39
Sendaigawa	8	0·37	0·37
Kuzuryūgawa	10	0·35	0·49
Aganogawa	19	0·21	—
Shinanogawa	19	0·45	0·46
Tonegawa	20	0·23	0·32
	Av.	0·32 ± 0·08	0·37 ± 0·11

The validity of the values of C_d for different rivers is also supported by the work of Miyake and Tsubota[1], who reported a similar constancy for river waters collected in Japan during July–August 1961 when the deposition rate was the smallest and the contribution of the ground deposits through leaching was the largest.

The cumulative ground deposit (D) caused by the continuous and constant deposition rate (R) can be shown by the following equation:

$$D = \frac{(1 - p_r)R}{\lambda_e}(1 - e^{-\lambda_e t})$$

where p_r has been given earlier and λ_e is the effective decay constant on the ground, which can be expressed as $\lambda_p + \lambda_w$, where λ_p is the radioactive decay constant and λ_w is the weathering constant.

The run-off by river of the ground deposits of cæsium-137 and strontium-90 can be estimated as 17·5 c. and 32 c. respectively per annum on the basis of the mean concentrations (C_d) as given earlier and the total discharge of 5×10^{14} l. of river water in Japan. By assuming the cumulative depositions of cæsium-137 and strontium-90 as 80 and 28 mc./km^2 respectively in the spring of 1962 and the total land area as $3·65 \times 10^5$ km^2, the weathering constant λ_w would be calculated as $6·0 \times 10^{-4}$ and $3·1 \times 10^{-3}$ respectively for these radionuclides. These values are much lower than those of the radioactive decay constants by factors of 8 for strontium-90 and 40 for cæsium-137. Half the ground deposits of cæsium-137 and strontium-90 would only be leached out after 1,150 and 220 years, respectively. Hence, no weathering factors need to be considered, especially for cæsium-137, in the future prediction of cumulative deposition. However, the slow penetration of the radionuclides into undisturbed soil and the mixing due to cultivation would result in the attenuation of the external exposure and the extent to which the radionuclides may enter the food chain.

METALLURGY

Grain Boundary Cavitation in Molybdenum

THE formation of cavities at grain boundaries under creep conditions had been observed in many metals and may lead to intercrystalline failure[1]. We have observed such cavitation in molybdenum wires of 0·010 mm diam. heated by electron bombardment to temperatures between 1,500° and 2,500° C (that is, above 60 per cent of the absolute melting point) and strained a few per cent at rates of 1·5–2·5 per cent elongation per hour. These cavities are of the two types identified by McLean in Nimonic-type alloys[2], wedge-shaped and ellipsoidal. Zener[3] suggested that wedge-shaped cavities are formed by the stress concentration at a grain boundary junction when sliding occurs on boundaries meeting there.

Table 1

	Stresses (lb./in.^{2}) on the molybdenum wire up to but not exceeding		
	1,000	2,000	3,000
No. of experiments	14	31	43
Percentage developing cavities	28	42	50
Percentage developing wedge cavities	7	26	36

Ellipsoidal cavities form at any point along a boundary which is roughly perpendicular to the strain axis. These cavities may link together, forming intercrystalline cracks. The proportion of experiments leading to the formation of cavities increases with the temperature of the molybdenum and with the total strain. The proportion of samples developing cavities, and the proportion of cavitated samples in which the cavities are of wedge type increase with the stress (Table 1). McLean reported the same relationship between cavity type and stress in alloys of Nimonic type[2].

Enhanced Age-hardening in Aluminium–Magnesium Alloys

ALTHOUGH the solubility of magnesium in aluminium is as high as 16·8 per cent (alloy contents are expressed as atomic percentages) at 450° C (ref. 1), and decreases to an estimated value of 1 per cent at room temperature, the alloys show an abnormally small response to age-hardening. Furthermore, there is no evidence to indicate that the ageing characteristics of these alloys are changed by small additions of third elements, as happens in other binary alloys such as aluminium–copper[2] and aluminium–zinc[3]. For example, the addition of 0·45 per cent zinc to aluminium–8 per cent magnesium causes only a small increase in

hardening[4] even though age hardening is very marked in a wide range of aluminium–zinc–magnesium alloys.

Polmear[5] has shown that trace additions (<0·1 per cent) of silver have a unique effect on the response of many aluminium–zinc–magnesium alloys to ageing in the medium temperature range (120°–220° C). Nucleation of the phase formed at these temperatures is facilitated so that the precipitate is very finely dispersed. Because of these structural changes, higher hardening is achieved. Possible effects of silver are now being sought in other alloy systems, and some interesting results have been obtained for several aluminium–magnesium alloys.

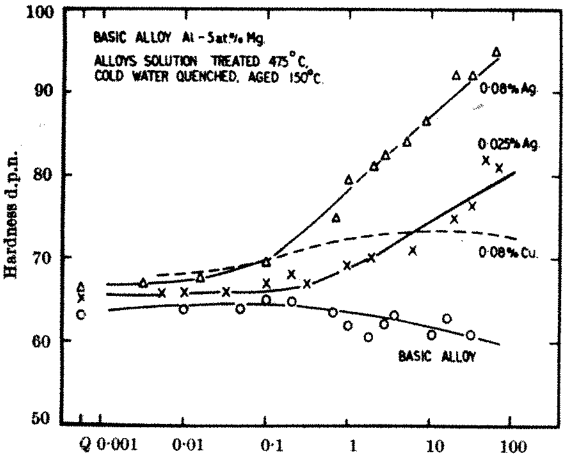

Fig. 1. Effects of small additions of silver and copper on the hardness–time curves for aluminium – 5 per cent magnesium aged at 150° C

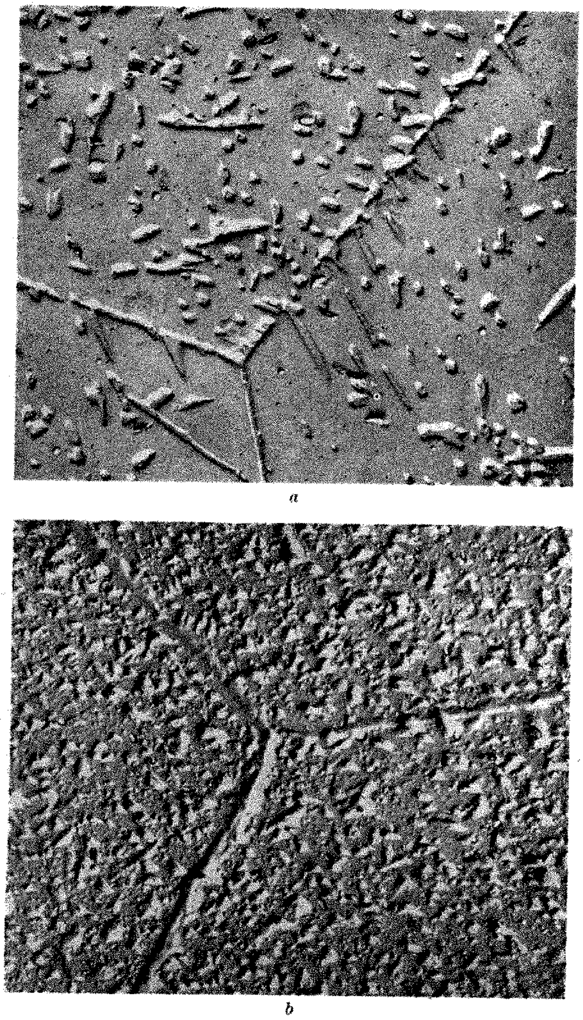

a

b

Fig. 2. Replica electron micrographs showing the effect of silver on the microstructure of aluminium–7 per cent magnesium solution treated 475° C, cold water quenched, and aged 10 days at 175° C. *a*, No silver; *b*, 0·12 per cent silver. (× 3,000)

It has been found that quite small amounts of silver may induce hardening in several wrought aluminium–magnesium alloys which normally do not age-harden. These effects were again evident in the medium temperature range, and Fig. 1 shows an example of this for the alloy aluminium–5 per cent magnesium aged at 150° C. Some hardening occurred on adding 0·025 per cent silver, and this became quite pronounced for the higher silver content of 0·08 per cent. The effect of this latter amount of silver was notably greater than that obtained on adding an equivalent amount of copper.

Binary alloys containing higher magnesium contents show some response to artificial ageing, and in these alloys silver both accelerated ageing and increased hardening. An examination was made of the effects of silver on the microstructure of one such alloy, aluminium–7 per cent magnesium aged at 175° C, and the results are shown in Fig. 2. It is clear that silver has again caused the precipitate to be finer and more uniformly dispersed.

These results suggest that silver may also have a unique effect on ageing in aluminium–magnesium alloys. The magnitude of these effects is less than those observed on adding silver to aluminium–zinc–magnesium alloys; but it is significant to note that each alloy system behaved in a similar way. This observation may contribute to the understanding of the mechanism by which silver modifies ageing in certain aluminium alloys. For example, it now seems possible that an interaction between magnesium and silver atoms may be important in this regard. The present results may also be of practical interest since wrought aluminium–magnesium alloys are used for many applications in which increased strength could be an advantage.

Both the theoretical and practical aspects are being studied in more detail, and results will be reported elsewhere.

We thank D. W. Glanvill and P. Curcio, who assisted in the experimental work.

CHEMISTRY

Negative Degrees of Freedom and the Phase Rule

IN a recent paper, Brynestad[1] states that the occurrence of negative degrees of freedom "is entirely improbable, in opposition to the statement of Halliwell and Nyburg[2]".

Most of Brynestad's paper is not concerned with this particular issue but with suggesting that S (the total entropy), V (the total volume) and the masses of each atomic species present in a system be used to discuss the phase rule rather than T, P and these masses. Lest there be confusion about this we should say we agree with Brynestad that this choice of variables has advantages particularly in defining the masses of each phase present, a feature missing from the T, P scheme.

The question at issue can be illustrated by a simple example[2]. Suppose we were to find two substances, A and

B, the triple points of which were so close that when placed in the same vessel the mutual, but limited, miscibility of the liquid phases brought the triple points into exact coincidence In this case we should have five co-existent phases. solid *A*, solid *B*, *A*-rich liquid, *B*-rich liquid and mixed vapour Then $F = -1$ The significance is clear the degree of freedom lost is that, having chosen *A*, not any *B* will suffice, *B* has to have specific physical properties

This conclusion is, to us, irrefutable A subsidiary issue, and one which seems to preoccupy Brynestad, is "How likely is this to happen?" According to Brynestad it is entirely improbable, a curious phrase, the meaning of which is made clearer by his comparison with the chance of failure of the second law of thermodynamics on a macroscopic scale We do not know how this estimate was arrived at and we do not believe that one can seriously discuss the chances of finding materials with the necessary physical properties in terms of normal probability theory In the strict application of the theory one would be forced to admit that no two people had the same height or weight

The issue resolves into a question as to how accurately can triple points be specified as to remain physically meaningful ? The accuracy cannot exceed the inevitable statistical fluctuations of the system Within these limits we do not see why, if one was patient enough to search, one would not find substances falling within the required limits We do not regard the practical issue of importance We do insist, however, that if a system having $F = -1$ were found the physical significance would be that which we have given

Formation of Peroxidic Precipitate in the Radiolysis of Uranyl Nitrate Ketone Solutions

It has been found that in the radiolysis of moist uranyl nitrate methyl isobutyl ketone solutions saturated with oxygen a yellow insoluble substance is formed This remains clinging to the walls of the irradiation vessel According to the weight analysis of the precipitate the most suitable formula appears to be UO_4 $4H_2O$

Gamma-radiation of cobalt-60 at the dose rate $0\ 6 \times 10^{16}$ to $4\ 0 \times 10^{16}$ eV/ml h was used Yield $G(U)$ is given by the number of uranium atoms in the precipitate formed due to the absorption of 100 eV in solution

The dose dependence of the precipitate formation is given in Fig 1 In the concentration range of 0 001–0 1 M $UO_2(NO_3)_2$ $6H_2O$ the initial yield $G(U) = 2\ 7$ At concentrations of 0 001 and 0 01 M the precipitate formation is stopped at corresponding doses as a consequence of the exhaustion of uranium from the solution At higher concentrations than 0 1 M the yield $G(U)$ is smaller and an induction period appears At concentrations above 0 1 M the precipitate is no longer formed

The water concentration has a noticeable influence on the precipitate formation At the concentration of water given only by the crystallinic water of $UO_2(NO_3)_2$ $6H_2O$, the precipitate is not formed at all With increasing concentration of water the precipitate yield is increased and reaches a value of 2 7 when the solution is saturated (about 1·3 M H_2O)

The influence of nitric acid is evident from Table 1 As nitric acid is also formed during the radiolytic decomposition of uranyl nitrate the decrease in $G(U)$ at doses above 2×10^{20} eV/ml may also be due to the action of that acid At concentrations higher than 0 1 M $UO_2(NO_3)_2$ and in the presence of water, some hydrolysis of uranyl nitrate evidently occurs The nitric acid formed in this way can also be responsible for the decrease of the precipitate yield at these higher concentrations and eventually for the enhancement of the induction period

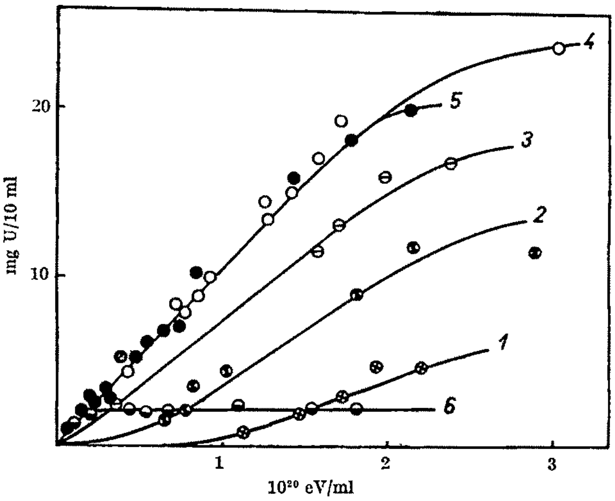

Fig 1 Dose dependence of precipitate formation in methyl isobutyl ketone saturated with water and oxygen 1, 0 5 M, 2, 0 2 M, 3, 0 15 M, 4, 0 1 M, 5, 0 01 M, 6, 0 001 M $UO_2(NO_3)_2$ $6H_2O$

Replacement of the oxygen atmosphere by air causes the appearance of the induction period even in solutions of 0 1 M $UO_2(NO_3)_2$ concentration and the yield $G(U)$ to decrease to 2 4 Consumption of the aerial oxygen is achieved at corresponding doses and the precipitate formation is stopped In a nitrogen atmosphere the precipitate is not formed at all

The precipitate formation in the two-phase systems (5 ml of water + 5 ml of ketone solution) is demonstrated by Fig 2 According to the distribution coefficients the uranyl nitrate concentration in the water phase is much greater than that in the ketone phase[1] From visual observation it is evident that the precipitate is formed predominantly at the interface In this interface a diaphragm, which is characterized by some mechanical strength, is gradually built Its existence impedes any further precipitate formation (Fig 2), only in the case of its mechanical destruction is the precipitate formation partially restored This remarkable mode of precipitate formation indicates that the most favourable reaction conditions are at the interface But by the building of the mechanical membrane these conditions gradually deteriorate, the mutual diffusion of reactants is suppressed and the reactions leading to the precipitate formation are stopped

Similar results were also obtained with methyl *cyclo*hexanone solutions The precipitate is formed only when the concentration is less than 0 2 M $UO_2(NO_3)_2$, at 0 05 M concentration $G(U)$ attains a constant value of 3 5 The same salient effect of water concentration was observed Addition of nitric acid inhibits the precipitate formation and even at a concentration of 0 028 M HNO_3 in 0 1 M $UO_2(NO_3)_2$ solution the suppression is complete

The mechanism of formation of the uranium peroxidic precipitate in these systems is apparently not a simple one One can assume that the precipitate is formed by reaction of the uranyl nitrate with peroxidic radicals

Table 1 0 1 M $UO_2(NO_3)_2$ SATURATED WITH WATER AND OXYGEN

Concentration of added HNO_3 mole/l 10^2	$G(U)$
0 0	2 7
2 8	2 0
7 0	1 2
14 0	0 0

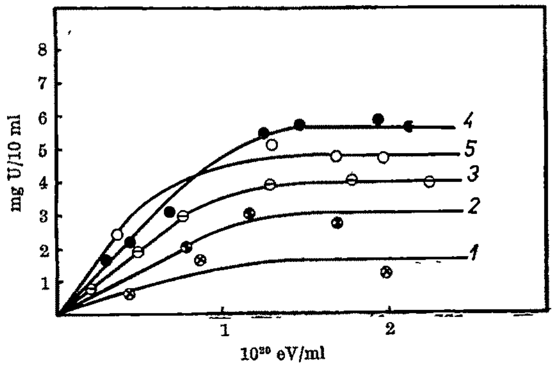

Fig 2 Dose dependence of precipitate formation in two-phase systems saturated with oxygen The total dose is the sum of doses absorbed in aqueous and in organic phase, the concentration of $UO_2(NO_3)_2\,2H_2O$ in aqueous phase 1, 1 M, 2, 0 5 M, 3, 0 2 M, 4, 0 1 M, 5, 0 01 M

and/or with hydrogen peroxide So long as the uranium peroxidic compound remains in solution it is decomposed by the radiolytic process As soon as its concentration exceeds the solubility limit, it is precipitated and so protected against further decomposition The existence of the induction period may be understood in a similar way The solubility of the uranium peroxidic compound can be affected by the nitric acid and consequently the yields *G*(U) and length of induction periods changed

New Fluorine Compounds of Technetium

IN contrast to the many fluorides, oxide fluorides and complex fluorides known for rhenium, only a few compounds of technetium have been reported, namely, the hexafluoride TcF_6 (ref 1), the trioxide fluoride[2], and salts of the quadrivalent $TcF_6^{=}$ ion[3]

Preliminary results in these laboratories indicate that the blue oxide tetrafluoride $TcOF_4$ (m p 134°) and the yellow pentafluoride (m p 50°) are formed as by-products in the direct fluorination of technetium metal The oxide tetrafluoride is much like the rhenium analogue[4,5] in appearance and in physical properties, and the magnetic moment (μ_{eff} (25°) = 1·76 Bohr magnetons, θ = 9°) is of the expected order for a d_1 compound The pentafluoride is isostructural with chromium pentafluoride and has orthorhombic symmetry (a_0 = 7 6, b_0 = 5 8, c_0 = 16 6 Å) It is more stable than rhenium pentafluoride[4,5], but begins to decompose in glass at 60°

Technetium hexafluoride can be reduced more easily than rhenium hexafluoride The action of a solution of potassium iodide in iodine pentafluoride (that is, of $I_2 + IF_4^-$) on the compound leads to a quadrivalent species, probably $KTcF_5$ (cf $KMnF_5$ (refs 8 and 9)), the corresponding reduction of ReF, gives Re(V) as the salt $KReF_6$ However, the action of solutions of alkali chlorides on TcF_6 in IF_5 gives Tc(V), and the salts $NaTcF_6$ and $KTcF_6$ have been prepared and characterized These yellow compounds are isostructural with the corresponding ruthenium derivatives[10,11] and differ from the rhenium salts[12] (Table 1) They obey approximately the Kotani rules of magnetic behaviour[13] for $d\varepsilon_2$ compounds, for example, for $NaTcF_6$ μ_{eff} = 2 25 Bohr magnetons at 25° and θ = 130°

We thank the University of Birmingham for a grant for technetium, Imperial Chemical Industries, General Chemicals Division, for the fluorine cell, and the Royal Society for a magnetic balance and for X-ray equipment The research was carried out during the tenure of a Department of Scientific and Industrial Research fellowship (to A J E) and a D S I R studentship (to D H)

Table 1 LATTICE CONSTANTS OF SOME COMPLEX FLUORIDES

Formation of 2-Iminothiazolidine-4-carboxylic Acid in the Cyanobromination of Lanthionine

Sullivan and Folk[1] found that the symmetrical thioether, lanthionine, is converted quantitatively into cysteine by the combined action of cyanogen bromide and sodium cyanide Although we could confirm the presence of cysteine in the reaction products we were unable to substantiate the quantitative nature of this conversion The heterocyclic compound 2-iminothiazolidine-4-carboxylic acid, which we detected in the mixture after reaction, could have been formed by further reaction of cysteine on the cyanogen halide and could account for our low cysteine yields

Initially, the method described by Sullivan and Folk[1] was followed meticulously, namely, 5 ml of a solution of lanthionine in 0 1 N hydrochloric acid (0 1 mg/ml) was added to 5 ml of an aqueous NaCN solution (5 per cent) One ml CNBr solution, prepared by adding 5 per cent NaCN to a saturated solution of bromine until the mixture was just colourless, was added After three consecutive boilings for 30 sec and coolings for 3 min the thiol content was estimated colorimetrically using either naphthoquinone sulphonate[2], phosphotungstic acid[3], or brucine[4] It soon became evident that the boiling period was insufficient to expel all CNBr which interferes with the estimation of thiol by any of these methods The lanthionine/CNBr reaction mixtures were then consequently boiled continuously for 10 min Positive tests for thiols were obtained by the nitroprusside test as well as by the methods referred to here The quantity of thiol formed was not consistent with that expected from the amount of lanthionine used as starting material and reproducibility of results was found to be poor A typical set of results is shown in Fig 1

It is known that thiazoline and thiazolidine derivatives are formed when sulphydryls are reacted on by cyanogen halides[5] The presence of 2-iminothiazolidine-4-carboxylic acid in the reaction mixture was verified by descending chromatography utilizing a solvent consisting of *sec* butanol, formic acid, and water (75 15 10)

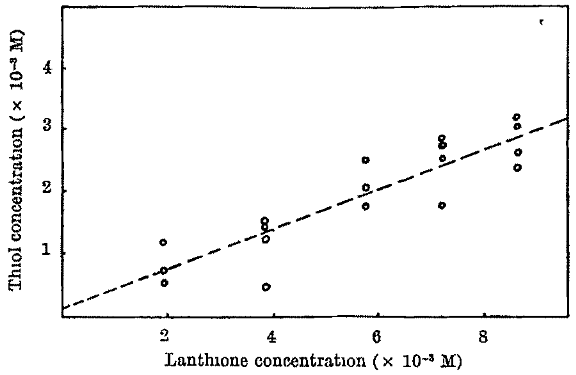

Fig 1 Original lanthionine concentration versus thiol concentration found after boiling a mixture of lanthionine, cyanogen bromide and sodium cyanide for 10 min

Dann *et al*[6] showed that lanthionine is attacked by alkali with the formation of thiazolidine derivatives In our experiments the solution rapidly turned alkaline as the hydrochloric acid was converted into HCN and expelled by boiling The resulting high *p*H of the solution, due to residual NaCN, could well be responsible for the conversion of some thio-ether into the heterocyclic compound

We conclude that under our reaction conditions conversion of thio-ether to sulphydryl by a boiling mixture of CNBr and NaCN, as claimed by Sullivan and Folk, does occur The quantitative value of the method is, however, impaired by the formation of 2-iminothiazolidine-4-carboxylic acid, which may be due either to cyclization of some of the liberated cysteine by the cyanogen bromide or to direct attack of alkali on the thio-ether

BIOCHEMISTRY

Sarcoplasmic Proteins in Pale, Exudative Pig Muscles

Among the histological aspects of the so-called white muscle disease or 'Muskeldegeneration' (pale, exudative muscle)[1] is the presence of dark bands which cross the muscle fibres when these are seen in longitudinal section[2,3] Bendall and Wismer-Pedersen[3] presented evidence that these bands consisted of denatured sarcoplasmic protein The denatured proteins appeared to be precipitated on to the myofibrils under the conditions of relatively low *p*H and high temperature, which obtain during post-mortem glycolysis in this disorder It has recently been shown, using starch-gel electrophoresis, that various glycolytic enzymes, including creatine kinase, are among the sarcoplasmic proteins which precipitate in exudative pork[4] These proteins remain soluble if the temperature during post-mortem glycolysis is relatively low or, irrespective of temperatures up to 37° C, if the ultimate *p*H is high

It would have been inferred from these findings that no bands of denatured sarcoplasmic proteins would form in muscle of high ultimate *p*H, but that in muscle of abnormally low ultimate *p*H (ref 2) such bands would have been especially marked In the course of our present investigation, however, we have observed (*a*) bands apparently of denatured sarcoplasmic protein in longitudinal sections of muscle fibres of ultimate *p*H 6 94; (*b*) the relative freedom from such bands in sections from muscle of ultimate *p*H 4·74, compared with sections from muscle of ultimate *p*H 5 40 Recent work by Scopes[6] on the solubility of sarcoplasmic proteins under various *p*H/temperature combinations affords an explanation of these anomalies, and also supports the view that the bands are in fact of sarcoplasmic origin He found that, whereas a high ultimate *p*H appreciably protects sarcoplasmic proteins against precipitation at temperatures up to 37° C, denaturation occurs almost independently of *p*H at 45° C It is known that the temperature of pig muscles may rise above 37°/38° C immediately *post mortem*[3], and in such cases it would appear that bands of precipitated sarcoplasmic proteins might form even although the *p*H is about 7 0 In this connexion it is of interest that the holding of pigs at 45° C for a period before slaughter causes a pale, exudative musculature to develop[7]

Scopes[6] also found that sarcoplasmic proteins were more soluble at *p*H 4 7 than at *p*H 5 4, although they were denatured to a greater extent at the former value, and it has been found that the percentage of sarcoplasmic protein which is extractable (at the *p*H of the muscle) attains a minimum when the ultimate *p*H is about 5 3 (ref 8) These findings could explain the prevalence of bands in muscles having an ultimate *p*H of 5 4 and their relative absence in muscles of abnormally low ultimate *p*H

Conversion of DPNH Dehydrogenase to DPNH-cytochrome Reductase by Thiourea

Investigations in this laboratory have shown that the various DPNH-cytochrome reductase preparations from heart and liver mitochondria described in the literature are fragments of the respiratory chain-linked DPNH dehydrogenase produced by the extraction method (acid-ethanol-heat or thermal degradation) used in the isolation of cytochrome reductases[1-5] By the action of these agents as well as various proteolytic enzymes, urea and under a number of other experimental conditions the purified dehydrogenase is also degraded to lower molecular weight cytochrome-reducing fragments This conversion involves major changes in many of the molecular and catalytic properties of the enzyme of which the emergence of cytochrome (and DCIP) reductase activity is but one feature The observations on thermal and proteolytic degradation have been confirmed and extended by Kaniuga[7,8], who has independently discovered the urea-catalysed transformation of the enzyme Acid-ethanol degraded DPNH dehydrogenase is not distinguishable from the preparations of Mahler *et al*[9], de Bernard[10], and Mackler[11], while the thermally degraded enzyme is in every respect identical with the preparation isolated by King and Howard[12] of which the major component is the Mahler enzyme[9] Although these investigations have directed attention to the fact that DPNH dehydrogenase is unstable under a variety of conditions[13] and readily breaks down to fragments with very different properties, very recently yet another DPNH oxidizing preparation derived from heart mitochondria has been described[14] which appears to be a breakdown product of the respiratory chain-linked DPNH dehydrogenase It is the purpose of this communication to show that, in terms of available evidence, the "DPNH dehydrogenase" of Chapman and Jagannathan[14] is not a naturally occurring enzyme but a fragment produced by the action of thiourea on DPNH dehydrogenase

The preparation of Chapman and Jagannathan is isolated from ETP by repeated incubation with thiourea at 0° As judged by its flavin content, it is a much lower molecular weight unit than the dehydrogenase isolated by Ringler *et al*[15] Further, its reported activity, even at the arbitrary fixed electron acceptor concentrations used, is much lower with ferricyanide and much higher with cytochrome *c* menadione, and other oxidants than that of the respiratory chain-linked enzyme For these reasons it appeared likely that thiourea (a known protein denaturing agent) degrades DPNH dehydrogenase to a modified fragment That this is indeed the case is shown in Table 1 Although thiourea modifies soluble DPNH dehydrogenase more rapidly than it does the particle-bound enzyme, the destruction of ferricyanide and emergence of cytochrome reductase activities are fast enough even in the case of ETP preparations to account for the formation of the derivative described by the Wisconsin group Further illustration of this fact is given in Fig 1, which shows the balance of DPNH dehydrogenase (as measured with ferricyanide) and of the thiourea product (as measured with cytochrome *c*) on sequential application of thiourea and phospholipase extractions and vice versa Treatment with thiourea under the exact conditions of Chapman and Jagannathan results in more than 99 per cent destruction of the dehydrogenase, as may be ascertained by direct assay as well as subsequent phospholipase digestion at 30° Prior extraction of the dehydrogenase with phospholipase *A* removes the material from which the reductase fragment originates thus subsequent incubation of the residue with thiourea yields very little cytochrome reductase

The differences between the thiourea product and the Mahler enzyme are explained by the fact that while acid-ethanol, thermal, and subtilisin degradations yield highly similar products, the action of low concentrations of urea and of thiourea produces fragments with different properties An example of this is the fact that urea and thiourea under the conditions tested do not increase DCIP reductase activity significantly. It should be emphasized that at equal concentrations thiourea is an even more effective transforming agent than urea itself Details of these observations will be published elsewhere[6].

Table 1 DEGRADATION OF DPNH DEHYDROGENASE BY THIOUREA

Exp	Conditions	Time of incubation (min)	Activities (μmoles DPNH/min/ml)		
			$Fe(CN)_6^{\equiv}$	Cytochrome *c*	DCIP
1	ETP, 0°, 1 19 M thiourea*	0	630	2 05	
		120	450	4 3	
		285	75	8 0	
		375	31	8 5

Inhibition of Protein Synthesis *in vitro* by Cycloheximide

CYCLOHEXIMIDE ('Actidione'), an antifungal antibiotic, isolated from *Streptomyces griseus*, was reported by Kerridge[1] to inhibit protein synthesis in *Saccharomyces carlsbergenesis* These observations have been substantiated by other workers[2,4] Recent investigations indicate that the changes produced by cycloheximide in intermediate metabolism, such as amino-acid, organic acid, adenosine triphosphate (ATP), and , other nucleotide production, is not responsible for the inhibition of protein synthesis[3,4] The data presented here will show that incorporation of leucine labelled with carbon-14 into protein in a cell-free system from *Saccharomyces pastorianus* is inhibited by low concentrations of cycloheximide

S pastorianus was grown as previously described[3] and cells were collected in the log phase of growth Approximately 12–15 gm of packed cells were suspended in 20–30 ml of a solution consisting of 0 05 M *tris*(hydroxymethyl) aminomethane-hydrochloric acid (*tris*-hydrochloric acid), *p*H 7 8, 0 005 M $Mg(OAc)_2$, 0 005 M potassium chloride; and 0 001 M mercaptoethanol Cells were broken in a French pressure cell (15,000–24,000 lb /in ^{2}) at 1° C Whole cells and cellular debris were removed by centrifugation at 20,000*g* in the cold and the extract was adjusted to *p*H 7 5 with 1 0 N sodium hydroxide The extract containing supernatant enzymes and microsomes necessary for protein synthesis was incubated for 15 min at 37° C with leucine labelled with carbon-14 and appropriate co-factors The reaction was terminated by the addition of 1 2 volumes of cold 10 per cent trichloroacetic acid (TCA) containing 0 1 M ^{12}C-DL-leucine The protein precipitate was washed and prepared for counting essentially by the method of Siekevitz[5] The protein precipitate was dissolved in 88 per cent formic acid and aliquots were added to 1-in planchets and counts were made in a windowless flow counter Protein was determined by the method of Lowry *et al* [6]

Table 1 REQUIREMENTS FOR INCORPORATION OF LEUCINE LABELLED WITH CARBON-14 INTO YEAST PROTEIN *in vitro*

Conditions	Incorporation of ^{14}C-leucine into protein (c p m)
Complete	532
+ 10 per cent TCA at zero time	10
+ 100 μg RNase	36
+ 100 μg cycloheximide *	90
+ 0 003 M $Mg(OAc)_2$	462
− 0 005 M $Mg(OAc)_2$	158
− 0 007 M $Mg(OAc)_2$	64
− KCl	290
− GTP	392
− ATP, PEP and pyruvic kinase	12

* 84 per cent inhibition

The complete reaction mixture contained 0 125 M *tris*-HCl buffer *p*H 7 5, 0 0095 M $Mg(OAc)_2$, 0 0075 M KCl, 0 001 M ATP, 0 0001 M guanosine triphosphate, 0 005 M phosphoenol pyruvic acid, 200 μg pyruvic kinase, 0 25 μc L-leucine-1-^{14}C specific activity 8 mc /mM, and 10 mg of protein (2 5 mg microsomal protein and 7 5 mg supernatant protein) in a volume of 2 ml Tubes were incubated for 15 min at 37° C and the reaction was stopped with 1 2 vol of 10 per cent cold TCA containing 0 1 M ^{12}C-DL-leucine RNase and cycloheximide were mixed with other reactants prior to the addition of the cell-free extract

The results in Table 1 show that protein synthesis *in vitro* is dependent on the presence of various co-factors and is inhibited by ribonuclease (RNase) and 50 µg/ml of cycloheximide In order to determine the effectiveness of cycloheximide, varying concentrations, from 0 1 µg/ml to 250 µg/ml , were mixed with other reactants prior to the addition of supernatant enzymes and microsomes The data in Fig 1 show that cycloheximide is a potent inhibitor of carbon-14 amino-acid incorporation into protein The 50 per cent inhibitory dose (ID_{50}) of the antibiotic for leucine incorporation was 0 2 µg/ml Thus, this process is of the same order of sensitivity to cycloheximide as is growth of cells of *S pastorianus*

A cell-free extract was pretreated with 25 µg/ml of cycloheximide and compared with the control and samples treated at zero time Pretreatment of the cell-free extract, containing microsomes, with cycloheximide before addition to the other reactants had very little, if any, effect on the levels of inhibition when compared with the samples treated at zero time (Fig 2) The inhibition ranged from 89 to 80 per cent at 2 5 and 10 min for non-pretreated samples and 90 to 86 per cent for pretreated samples for the same time-intervals Under these experimental conditions the maximum inhibition never exceeded 90 per cent and consistently ranged from 80 to 90 per cent in all the tests Whether the inability of high concentrations of the antibiotic to inhibit completely protein synthesis *in vitro* is due to the experimental conditions used or to the true nature of the antibiotic action has not been determined

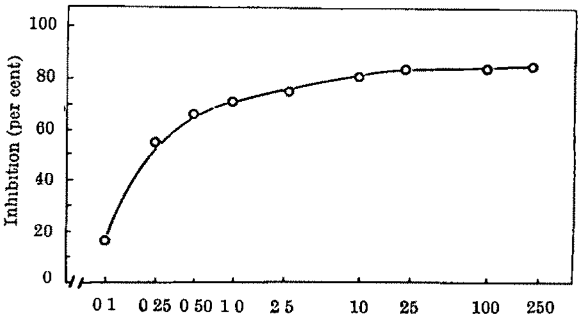

Fig 1 Effect of various concentrations of cycloheximide (0 1–250 µg/ml) on incorporation of ^{14}C-leucine into protein (see Table 1 for conditions) Cycloheximide was mixed with other reactants before addition of microsomes and supernatant Results for complete and treated samples were corrected for ^{14}C-leucine incorporated into the blank (complete + 10 per cent TCA at zero time)

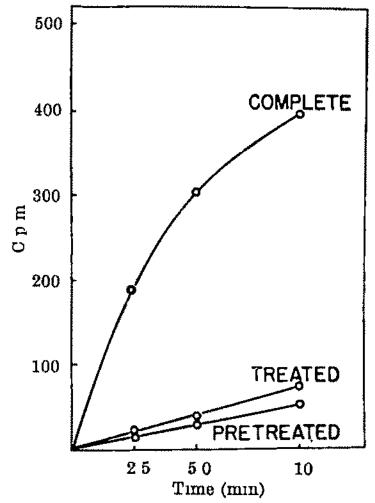

Fig 2 Effect of pretreatment of supernatant and microsomes with cycloheximide Conditions for this experiment were the same as those in Table 1 except the reaction mixture was contained in 1 ml and 5 0 mg of protein (supernatant and microsomes) and 0 5 μc DL-leucine-1-^{14}C, specific activity 54 6 mc /mM, was added to each tube The microsomal and supernatant mixture was pretreated with 25 μg/ml of cycloheximide 10 min before mixing with other reactants The reaction was stopped at various time-intervals by addition of cold 10 per cent TCA to each tube The ^{14}C-leucine incorporated into the blank (complete minus ATP, PEP and pyruvic kinase) was subtracted from that incorporated into complete, treated and pretreated samples

The site of action of the antibiotics chloramphenicol[7] and puromycin[8,9] has been traced to protein synthesis Specifically, they inhibit the polymerization of amino-acids to form protein on the microsomes Previous investigations[4] showed that cycloheximide does not affect the first two enzymatic steps in protein synthesis, that is, amino-acid activation and transfer of amino-acids to soluble ribonucleic acid (*s*–RNA) Thus the evidence indicates that the antibiotic affects the third enzymatic step either by inhibiting the transfer of amino-acids from amino acyl *s*–RNA to the microsomes or the polymerization of amino-acids into protein The effects of cycloheximide on yeast metabolism resemble those of chloramphenicol in bacterial systems Both antibiotics inhibit protein synthesis, stimulate ribonucleic acid synthesis, and partially inhibit deoxyribonucleic acid synthesis

This investigation was supported by research grant A110025-11 from the National Institutes of Health, U S Public Health Service

Deoxyribonucleic Acids of Marine Mollusca

RECENT investigations have demonstrated a wide range of deoxyribonucleic acid (DNA) base compositions which correlate well with other taxonomic criteria in both bacteria[1-4] and protozoa[5,6] The available data for metazoans are less extensive[4,7] However, a considerable variation in DNA base compositions is found among the porifera[8], and the published analyses for three species of molluscs[4,9] indicate the probability of a range of compositions in that phylum. This communication describes work on several other species of molluscs DNA was isolated from sperm on testes using a modification[10] of Marmur's procedure[11] Base compositions were estimated from density gradient centrifugation studies[13] and from thermal denaturation temperatures[12] The results are recorded in Table 1

Table 1 PROPERTIES OF MOLLUSC DNA's

Class and species	Tm (°C)	% GC*	Density (g/ml)†	% GC§
Lamellibranchia

* Percentage guanine-cytosine calculated from thermal denaturation temperature, Tm (12)
† Relative to *E coli* buoyant density, 1 710 g/ml (ref 13)
‡ Heat denatured DNA
§ Percentage guanine-cytosine calculated from buoyant density

All DNA samples were unimodal with respect to buoyant density and thermal denaturation temperature Representative lamellibranch (*Crassostrea gigas*) and gastropod (*Haliotis kamtschatkana*) DNA's were unimodal in the cæsium chloride gradient after heat denaturation All the mollusc DNA's were rich in adenine-thymine, those of the lamellibranchia containing the largest amount of these bases The range of guanine-cytosine (GC) contents was 11–12 per cent In common with other nucleic acids of extreme base composition, there is some divergence between GC content calculated from thermal denaturation temperatures and from buoyant densities[12,13] There is reasonable correlation of the foregoing results with earlier data Thus Sueoka, using the buoyant density technique, obtained a GC content of 37 per cent (38 per cent using the method of calculation of Marmur and Doty) of DNA in the quahog, *Venus* (*Mercenaria*) *mercenaria* L [4], and Lee and Barbu, by chemical analysis, found 31 per cent GC in the blue mussel, *Mytilus edulis* L , DNA[9]

The two prosobranch gastropods have a mean GC content 7–8 per cent higher than the mean value of the lamellibranchs and none of one class intrudes into the region of the other It is of interest that the GC content, 35 per cent, of a cephalopod, *Octopus vulgaris lam* , DNA[9] lies in the mid-region of the range bounded by the lamellibranchs and the prosobranch gastropods

We thank Mr J C Smith for samples of *P staminea*, *C nuttalli* and *P lewisii* testes and *H kamtschatkana* sperm, and C E Woelke for *C gigas*, *S giganteus* and *P staminea* sperm

Metabolism of 3-Hydroxyanthranilic Acid labelled with Carbon-14 Carboxyl in Normal and Neoplastic Mice

THE *o*-aminophenol, 3-hydroxyanthranilic acid (3-OHAA) is a metabolite of tryptophan normally present in urine in trace quantities Recent observations have been concerned both with the carcinogenic property of 3-OHAA to induce cancer of the bladder and with elevated levels of urinary excretion of 3-OHAA in neoplastic diseases[1]

A limited amount of carboxyl-^{14}C-labelled-3-OHAA (^{14}C-3-OHAA) was available for experiments with a few animals The carboxyl-^{14}C-labelled-3-OHAA was given to control mice and mice with transplantable tumours of mouse origin in an attempt to examine the influence of these tumours on metabolism of 3-OHAA. These preliminary observations indicate a lowered rate of metabolism of 3-OHAA in the ascites mice accompanied by a reduced level of urinary quinolinic acid labelled with carbon-14 (^{14}C-QA)

Female Swiss albino mice were used in these experiments Three homologous transplantable tumours were used in this work The mammary adenocarcinoma appears spontaneously in about 3 per cent of our virgin females when 6–8 months of age The Ehrlich ascites tumour has been maintained in our mice in ascites form for several years by intra-abdominal injection of a suspension of tumour cells at intervals of 10–15 days A transplantable brain tumour (glioblastoma multiforme) was induced by intracranial implantation of methylcholanthrene pellets[2] Tumour mice were injected with ^{14}C-3-OHAA 5 days after intracranial transfer of the brain tumour cells and 9 days after intra-abdominal transfer of the ascites cells Previous experiments demonstrated active growth of tumours at this time A moribund condition usually developed 5–7 days later

The carboxyl-^{14}C-labelled-3-OHAA was from a preparation previously described[3] It was injected by intra-abdominal route in doses of 0 0011 mM containing 0 024 µc /g body-wt Respiratory carbon dioxide and urine were collected and quinolinic acid (QA) values determined on all urines by microbiological assay[4] Crystalline QA was isolated by column chromatography[5] Small samples of QA were combusted to carbon dioxide and the carbon-14 measured by the method of Van Slyke, Steele and Plazin[6] The tumour from a mammary tumour mouse was excised and homogenized. Aliquots were dried in Van Slyke combustion tubes, and analysed for total carbon and for carbon-14 content[6]

The observed initial rapid oxidative metabolism of ^{14}C-3-OHAA in the normal mice (Fig 1) may account for the rather low level of ^{14}C-QA (13 per cent) found in the urine This is in contrast to the relatively higher percentage (46 per cent) conversion of ^{14}C-3-OHAA to carbon-14 by mouse liver cell free extracts[7] A small store of QA is indicated in the normal mice (Table 1) from the 84 per cent ratio of specific activity of isolated ^{14}C-QA to the administered dose of ^{14}C-3-OHAA A change in the ratio of the specific activity of isolated urinary ^{14}C-QA to the injected dose of ^{14}C-3-OHAA indicated an alteration of the metabolism of 3-OHAA in the tumour mice since the test dose (mg/g of body-wt) was the same in these experiments

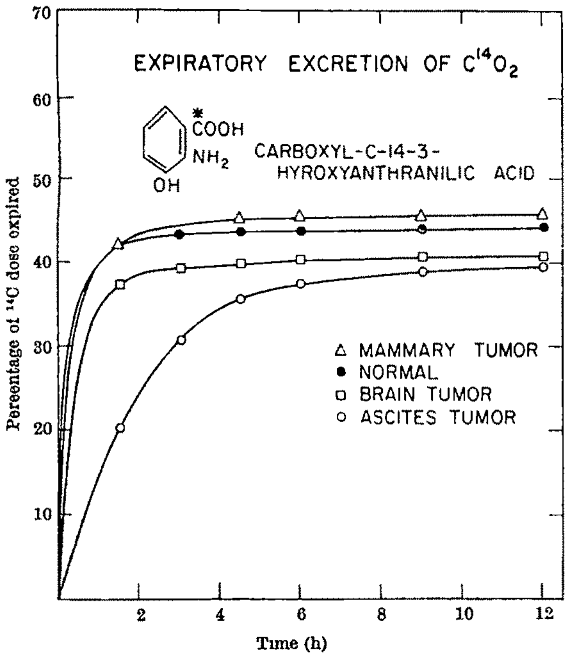

Fig 1 Twelve-hour excretion of $^{14}CO_2$ by mice after carboxyl-^{14}C-3-hydroxyanthranilic acid administration

The reduced amount of carbon-14 (6 7 per cent) present as QA in the urine of the mammary tumour mice as compared with the level (13 per cent) found in normal urine may be accounted for by several mechanisms (1) an increased rate of metabolism of ^{14}C-QA into ^{14}C-nicotinic acid, ^{14}C-N^1-methylnicotinamide[8] or ^{14}C-N^1-methyl-2-pyridone-5-carboxamide; (2) increased conversion of compound I into glutarate or acetate which leads to formation of $^{14}CO_2$ (ref 9), (3) free or conjugated ^{14}C-3-OHAA Since the carbon-14-label is in the carboxyl position, none of the observed activity of carbon-14 could be present as urinary picolinic acid Portions of a homogenate of the excised mammary tumour were analysed for total carbon-14 to determine if a major amount of the injected dose of ^{14}C-3-OHAA was bound by the tumour. The carbon-14 analysis accounted for only 0 5 per cent of the injected dose

Table 1 12-Hour Urinary Excretion of Quinolinic Acid after Injection of Carboxyl-^{14}C-3-Hydroxyanthranilic Acid

Type of tumour		Normal	Mammary	Brain	Ascites
Sp act of inj 3-OHAA, µc /m mole	a	21 985	21 985	21 985	21 985
3-OHAA, inj m mole*		0 038	0 043	0 031	0 032
C-14 inj , µc	b	0 842	0 940	0 666	0 704
^{14}C content of urine per cent of dose		29 85	26 57	20 35	21 78

Per cent of injected $^{14}C = \frac{100e}{b}$		13 18	6 70	6 01	3 41
Ratio $= \frac{\text{Sp act of excreted Q-acid}}{\text{Sp act of inj 3-OHAA}} = d/a$		0 841	0 953	0 911	1 082

* Injected 0 011 mM/10 g mouse

The slower rate of metabolism of 3-OHAA into $^{14}CO_2$ by the brain tumour animals as well as the lower levels of carbon-14 in their urines assumes greater interest when we consider the relative size of the brain tumour mass (175 mg) as compared with the excised mammary tumour (6 5 g) In view of the small size of the excised brain tumour, it is difficult to assume that the lowered rate of metabolism of ^{14}C-3-OHAA is due to endogenous metabolism by the tumour tissue

Pal and Christensen[10] have shown cell transport and binding of pyridoxal and pyridoxine occurred in ascites tumour cells Their *in vitro* study indicated pyridoxal binding through amino groups of cellular proteins and amino-acids through the aldehyde group of pyridoxal. It should be considered that pyridoxal binding may occur through hydrogen binding of the hydroxyl group on the pyridoxal ring In view of the foregoing findings obtained with tritium-labelled pyridoxal, several mechanisms may be considered to account for the slower metabolism of ^{14}C-3-OHAA observed in the ascites tumour animals Initial uptake of ^{14}C-3-OHAA by the tumour cells may have occurred with hydrogen binding through the hydroxyl group to cellular components The weak nature of the hydrogen binding would allow a return of the ^{14}C-3-OHAA to body fluids for subsequent metabolism into $^{14}CO_2$ via the acetate pathway[9] The ^{14}C-3-OHAA in the ascites cells may also be split into the straight-chain compound (1-amino-4-formyl-buta-1 3-diene-dicarboxylic acid) and afterwards bound to amino-groups through the terminal aldehyde group This mechanism would be similar to pyridoxyl binding with the aldehyde compound being metabolized into $^{14}CO_2$ and ^{14}C-QA It is also possible that the aldehyde compound formed by host metabolism may be externally bound to cells through the aldehyde group and afterwards metabolized into $^{14}CO_2$ and ^{14}C-QA The lower ^{14}C-QA values (Table 1) obtained in the urines of the tumour mice as compared with normal mice may possibly be accounted for through accelerated activity of enzyme II[7] This enzyme decarboxylates the aldehyde compound to form picolinic acid, which would leave less substrate available for ^{14}C-QA formation

Preparation of 2-Isopropylthiamorpholin-3-one-5-carboxylic Acid

ISOVALTHINE is a new sulphur-containing amino-acid which is isolated from the urine of hypercholesterolæmic patients[1,2] A molecular model of isovalthine suggests a possibility of forming a thiamorpholinone derivative by the intramolecular cyclization Such thiamorpholinone derivative may also be produced in the animal body and have some biological effects From these considerations, 2-isopropylthiamorpholin-3-one-5-carboxylic acid was prepared from L-isovalthine and its biological effect was examined

L-Isovalthine (30 mg, decomposition point 186° C)[3] was heated in a small flask immersed in an oil-bath at about 190° C for 15 min During this operation a vacuum was applied to the flask to remove water which was produced during cyclization After cooling the flask to room temperature, the brown residue was dissolved in a small amount of 2 N ammonia and filtered The filtrate was made weakly acidic with acetic acid, and transferred on a column containing strong cation exchanger (*H*-form) The effluent and water washings were collected and evaporated to dryness in vacuum The residue was taken up in ether and filtered The ether solution was concentrated to a proper volume and left standing at room temperature Needles obtained were recrystallized from ether, giving 18 mg, m p 140° C $[\alpha]_D^{17} = +4\ 1°$ in ethanol It was slightly soluble in water, soluble in ether, and easily soluble in methanol, ethanol, and alkali

Anal calc for $C_8H_{13}O_3NS$ C, 47 27, H, 6 45, N, 6 89, found C, 47 18, H, 6 44, N, 6 89 The molecular weight (calculated, 203) was found to be 186 and 217 by the Rast method The ultra-violet absorption spectrum of the compound is shown in Fig 1 $\lambda_{max} = 202\ 8$ mμ ($\varepsilon = 13\ 000$) Since another synthetic sample of thiamorpholin-3-one-5-carboxylic acid prepared from *S*-(carboxymethyl)-L-cysteine[4] also showed a similar absorption, the $\lambda_{max} =$ 202 8 mμ band is thought to be specific for the thiamorpholinone ring The infra-red spectrum of the compound is shown in Fig 2

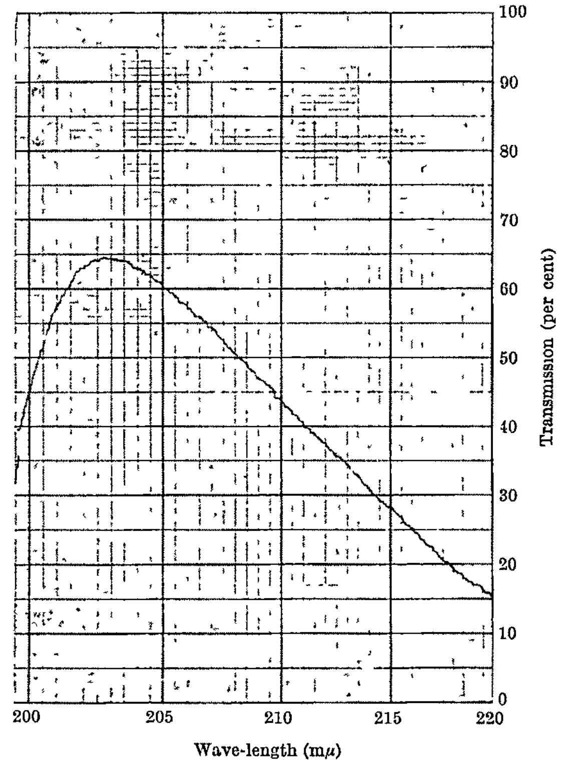

Fig 1 Ultra-violet absorption spectrum of 2-isopropylthiamorpholin-3-one-5-carboxylic acid in methanol solution

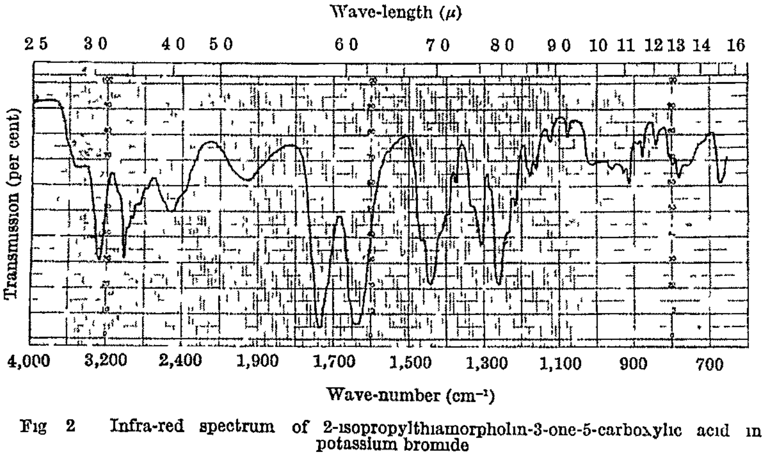

Fig 2 Infra-red spectrum of 2-isopropylthiamorpholin-3-one-5-carboxylic acid in potassium bromide

Although the thiamorpholinone derivative prepared as described here is similar in chemical structure with amytal, it has neither hypnotic effect on mice nor inhibitory effect on the electron transport system of isolated rat liver mitochondria

We thank Dr T Matsukawa, Takeda Research Laboratory, for the elemental analysis, and Prof Dr H Yamasaki and Dr K Utsumi for their help in testing the biological functions This work was supported by research grants from the Rockefeller Foundation, the U S National Institutes of Health (*HE*-07419), and the Ministry of Education of Japan

Configuration of Urinary Isovalthine

ISOVALTHINE crystals first isolated from urine were rhombic plates which gave DL-alanine after treatment with Raney nickel Needle-shaped crystals were obtained by condensation of L-cysteine and (±)-α-bromoisovaleric acid They were a mixture of L- and L-allo-isovalthine, and readily converted into the rhombic form by heating in hydrochloric acid[1,2]

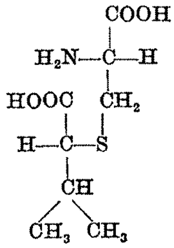
Recently we have synthesized L- and L-allo-isovalthine separately by using (+)- and (−)-α-bromoisovaleric acid The resolution of (±)-α-bromoisovaleric acid into each of optical antipodes was achieved by using ephedrine Optical rotation of the isomer synthesized from L-cysteine and (+)-α-bromoisovaleric acid was $-52\ 4°$ ($[\alpha]_D^{17}$ in 2 N hydrochloric acid) and that of the other isomer synthesized from (−)-α-bromo acid was $+82°$ ($[\alpha]_D^{17}$ in 2 N hydrochloric acid) The decomposition point of the isomer of $[\alpha]_D = -52\ 4°$ was 186° C and that of $[\alpha]_D = +82°$ was 185° C The elemental analyses of these isomers were correct, and these single isomers gave L-alanine after treatment with Raney nickel

On an amino-acid analyser (Beckman model 120 *B*), the needle-shaped crystals yield two peaks between serine and proline at the effluent ml of 183 and 196 (30° C, *p*H 3 24, 0 2 N sodium citrate buffer, 150 cm column) The isomer of $[\alpha]_D = -52$ 4° yields one peak ($C_{HW} = 20$ 5) and overlaps 196 ml peak of the needle The other isomer of $[\alpha]_D = +82°$ yields also one peak ($C_{HW} = 19$ 2) and overlaps the 183 ml peak of the needle The rhombic plates yield two peaks with the same effluent ml as that of needles, and the mixture of these two racemic compounds gives just two peaks The calculated ratio of 183 ml peak to 196 ml peak was as follows needle, 4 6, rhombic plate, 9 1

Isovalthine in urinary acidic amino-acid fraction yields one peak at 196 effluent ml and the peak overlaps the isomer of $[\alpha]_D = -52$ 4° The urinary isovalthine fraction is prepared as follows 250 ml of urine is made weak acidic and transferred on a column containing 200 g of the acetate form of 'Amberlite *AG*-45' The column is washed with 600 ml of 0 1 N acetic acid and then eluted with 2 l of 2 N acetic acid The 2 N acetic acid eluant is transferred on a column containing 100 g of strong cation exchanger (*H*-form) The column was washed with water and eluted with 500 ml of 2 N ammonia The ammonia solution is evaporated to dryness in vacuum at 40° C The residue is dissolved in 10 ml water and 2 ml of the filtrate is analysed on amino-acid analyser The recovery of urinary isovalthine was about 75 per cent Further treatment for the purification changes urinary isovalthine gradually into the mixture of L- and L-allo-isovalthine Therefore, it is difficult to isolate urinary isovalthine as a single isomer without changing its configuration

On the paper electropherogram prepared by Ubuka's method[3], the needle-shaped crystals yield also two bands with almost equal concentrations Urinary isovalthine and the isomer of $[\alpha]_D = -52$ 4° overlap the slower-moving band of the needle, and the isomer of $[\alpha]_D = +82°$ overlaps the faster-moving band of the needle

For these reasons, it may be concluded that urinary isovalthine has the same configuration with the compound synthesized from L-cysteine and (+)-α-bromoisovaleric acid, this may be called L-isovalthine (+)-α-Bromoisovaleric acid is known to be derived from D-valine by the treatment with nitrosyl bromide and to be converted into D-valine by the treatment with ammonia If (+)-α-bromoisovaleric acid is assumed not to change its configuration during condensation with L-cysteine, the configuration of L-isovalthine may be written as follows



It requires some effort to find out the patients who excrete isovalthine in their urine Experimental isovalthinuria, however, can readily be induced in the guinea pig by the administration of isovaleric acid, dehydrocholic acid, cholic acid, or 22,25-diazacholestanol ('*SC*-11952') These inducers take effect on the following times after administration 200 mg/kg/day of isovaleric acid, second day, 12 5 mg/kg/day of dehydrocholic acid, 5–7 days, 12 5 mg/kg/day of cholic acid, third week, 5 mg/kg/day of 22,25-diazacholestanol, second week Although isovaleric acid is the best inducer for some animals, isovaleric acid-1-^{14}C has not significantly incorporated into urinary isovalthine[4] The administration of cholesterol alone does not induce isovalthinuria up to the end of the fourth week

Table 1 EXPERIMENTAL ISOVALTHINURIA INDUCED BY BILE ACID AND CHOLESTEROL IN GUINEA PIG

Inducers	Isovalthine excreted µmoles/100 ml urine 5–7 days	Second week	Third week	Fourth week
Dehydrocholic acid (12 5 mg/kg/day)	0 38	0 76	0 55	0 45
Dehydrocholic acid (12 5 mg/kg/day) + cholesterol (250 mg/kg/day)	0 75	1 98	0 85	0 28

But its administration with dehydrocholic acid appears to enhance isovalthine excretion as shown in Table 1

Isovalthine is also obtained by using liver homogenate of guinea pig from isovaleric acid or α-ketoisocaproic acid as substrates Glutathione and air appear to be necessary for this reaction As cysteine is less effective than glutathione, the first product synthesized in the reaction mixture is assumed to be a glutathione-isovaleric acid conjugate The assumption, however, has not so far been verified

A Comparison of Plant Cell Division Inducers from Coconut Milk and Apple Fruitlets

COCONUT milk is recognized as a rich source of plant cell division inducers, which have become known as kinins[1–5] Recently, apple fruitlets were also shown to be a rich source[6], and the kinins have been extracted from this tissue and concentrated[7] The results showed that the extract contains at least four and probably five independently active kinins as revealed by the tobacco stem pith test[8] In this test, blocks of tobacco pith are cultured singly in small tubes on a sucrose–mineral salt medium which also contains the auxin, indolyl-3-acetic acid An 'active' extract, added as a supplement to this medium, induces cell division and the formation of microscopically visible clusters of new cells after 14 days In control cultures the cells enlarge but do not divide Reduced nitrogen compounds and hexitols are not required in this assay, nor do they enhance the effect of active extracts as they do in the carrot root phloem test[9], which has been used in many studies on coconut milk

The kinins obtained from coconut milk and from apples were compared by subjecting coconut milk to the extraction, purification and fractionation procedures developed for apple fruitlets Volatile solvents added in the course of purification procedures were removed by evaporation under reduced pressure before assaying the activity of fractions by the tobacco stem pith test

Coconut milk (500 ml) from fresh, nearly mature coconuts was subjected to the purification procedure developed for apple extract[7] The most efficient purification steps in this scheme are those which use 'Dowex–50–H$^+$' and carbon columns The purified coconut milk, so prepared, showed perceptible cell division activity at a concentration of 0 1 mg dry weight/l

Except for slight activity in the water effluent from 'Dowex–50–H$^+$', which was found for coconut milk but not

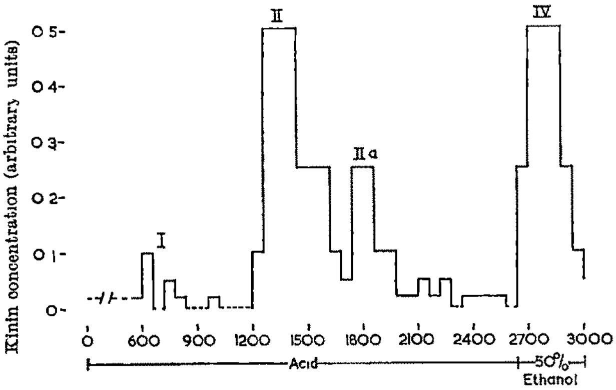

Fig 1 Chromatography on a 'Chromax' rolled-paper column of partially purified coconut milk kinins The eluting solvents were *n* butanol/glacial acetic acid/water (4 1 1), and 50 per cent ethanol

apple extract, the behaviour of the kinins from the two sources was the same

The purified extract was chromatographed on a 'Chromax' 3502 paper roll column (L K B Produktor, Stockholm) in *n*-butanol/glacial acetic acid/water (4 1 1, v/v) and then in 50 per cent aqueous ethanol Fifty-four × 60 ml fractions of acid eluate were collected and seven of aqueous ethanol Each fraction was assayed at five dilutions as previously described for apple extract[8]

The greatest dilution giving perceptible activity was plotted against the volume of eluate (Fig 1) This revealed four major peaks of activity compared with five given by apple extract[7]. A sample of each of the peaks was chromatographed on a paper strip in methyl ethyl ketone/acetic acid/water (4 : 1 1, v/v) The R_F values of these peaks as well as those of the peaks found in apple extract are shown in Table 1

Table 1 PAPER CHROMATOGRAPHY OF KININS OBTAINED FROM COCONUT MILK AND FROM APPLE FRUITLETS IN METHYL ETHYL KETONE/ACETIC ACID/WATER (4 1 1, v/v)

Peak	R_F values Coconut milk	Apple extract
I	0 71–0 79	0 76
II	0 42–0 56	0 46–0 50
IIa	0 44–0 53	0 46–0 50
III	Absent	0 27–0 33
IV	0 05–0 27	0 00–0 15

But for the absence of peak III in coconut milk, there is a close correspondence between the R_F values of the kinins from the two sources Although peak II*a* has been observed several times in eluates from 'Chromax' columns it has invariably given the same R_F as peak II on paper strips Presumably the resolution on the 'Chromax' column developed with *n*-butanol–glacial acetic acid–water is superior to that of paper strips developed with methyl ethyl ketone–acetic acid–water

It was reported previously[7] that treatment of a mixture of peaks III and IV with normal hydrochloric acid gave rise to a peak with the R_F of peak II It has now been found that treatment of peak IV from both apple fruitlets and coconut milk on 'Dowex–50–H$^+$' produces peaks which have R_F values corresponding to I, II and III Perhaps, therefore, peak IV is the native kinin in each case and the other peaks are artefacts produced by the 'Dowex–50–H$^+$' step in the purification procedure However, the appearance of III after 'Dowex–50–H$^+$' treatment of coconut milk peak IV contrasts with its apparent absence in purified coconut milk No satisfactory explanation of this discrepancy can be given

From both sources, kinins which have (with the exception of peak III) corresponding R_F values can be obtained Further, degradation of peak IV gives an identical result in each case These two facts suggest, but do not prove, that the chemical nature of the kinin or kinins from the two sources are very similar or even identical This view is supported by the corresponding behaviour of the kinins from both sources in the purification steps

PHYSIOLOGY

Electrical Activity of the Parturient Human Uterus

FUNCTIONAL uterine disorders cannot be diagnosed with certainty and the progress of labour is doubtful even in those instances when the patients are labelled clinically 'normal' The fact that most women eventually deliver a normal new-born without severe complications is of no comfort to the attending physician at the time of the onset of labour, for he has no guarantee, except a statistical one, that his given patient will have a quick and uncomplicated delivery His uncertainty is the more disturbing, for the outcome of labour will to a great extent depend on his diagnostic and prognostic skill in recognizing functional uterine disorders and his choice of management

This article reports preliminary work on a new technique of apparent diagnostic and prognostic value The new method yields a tracing of the electric activity, of the parturient human uterus Naturally it can be applied to the non-pregnant uterus as well The method, when combined with the 'extra-ovular pressure' technique[1], allows the simultaneous recording of the electric and mechanic activity of the uterus for hours or repeatedly during several days in non-anæsthetized patients The significance of knowing the character of the electric activity is the following

The amniotic pressure tracing describes accurately the quantity and to a large extent the quality of the uterine activity[1] It informs us about the resting and active pressure, the frequency and duration of cyclic activity, and by the shape of the pressure curve about the extent of propagation together with the synchrony of activity However, all this valuable information, no matter how accurate, is insufficient for predicting the course of labour even in those patients who are labelled as clinically 'normal' Not infrequently we observed that quantitatively and qualitatively excellent activity failed in securing normal progress

Those clinicians for whom intra-amniotic pressure tracings were not available concluded that, although the clinical symptoms of effective uterine activity were apparent in a given patient, she failed in progress most likely because the quantity or quality (or both) of uterine effort must have been inadequate Those obstetricians who did have the evidence in the tracings of a quantitatively and qualitatively excellent uterine activity concluded that the reasons for slow or no progress lay in the cervix, resisting dilation Several hundred pressure tracings now allow us to state with certainty that clinically perfectly 'normal' patients may completely

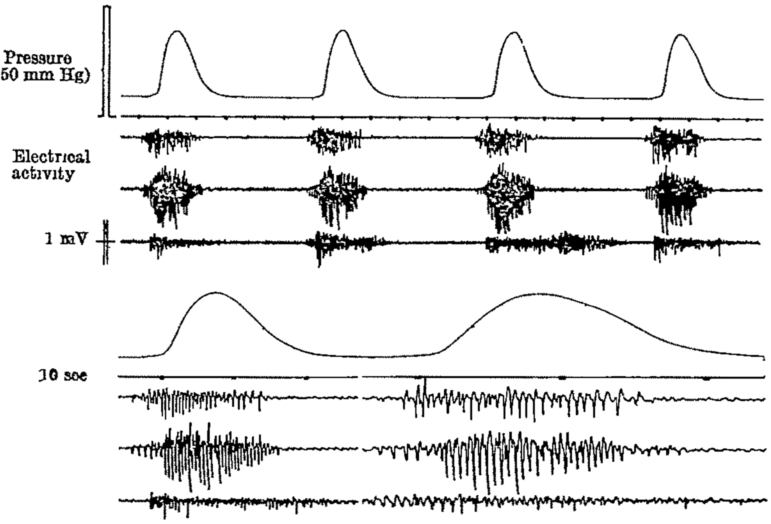

Fig 1. Electrical and mechanical activity of the parturient rabbit uterus. Note the synchrony in electrical activity at the ovarian, mid and cervical uterine portions. Note the uncomplicated shape of the pressure curves

fail in their progress of labour, not only for hours but for days, in spite of excessive uterine activity. More than that, patients may fail in their progress even in those instances when the cervix has all the clinical qualities which permit normal or rapid progress.

It is apparent, therefore, that the classic clinical concepts concerning prolonged labour, uterine inertia, cervical distocia, the arrest of labour, etc., are to a large extent unsatisfactory and must be revised. The more so because it has been shown[2] that when patients with fœtal death or with missed abortion are induced to deliver by hypertonic solutions under the most unfavourable conditions, that is, poor spontaneous activity, closed, hard and long cervix, they deliver during a very short period of 2·7 h (on the average) after the clinical onset of labour. The intra-amniotic injection of hypertonic solutions has two known effects: the suppression of placental function (and most likely that of the amniotic membranes) and the increase in uterine volume. It is significant that these effects create an obstetrical situation in which patients deliver quickly and predictably. We are forced to conclude that the unpredictability of normal labour lies in our incomplete understanding of placental function.

The concepts of the local effect of placental progesterone[3], the consequent endocrine and functional asymmetry[4] of the uterus permit a reasonable explanation of slow progress (or no progress) in those patients whose uterine activity is normal or excessive. A clinically not apparent unfavourable condition is that when the placenta has a fundal or partly fundal implantation. In this condition, activity would seem to begin at the lower uterine segment and will then propagate in the wrong, upward, rather than the downward direction. The pressure tracing does not reveal the direction of the activity wave.

It is the recording of the electrical activity at different portions which shows clearly not only the character but also the direction in the spread of the electrical activity. If electrical activity is recorded together with the amniotic pressure, uterine activity is described in full detail.

We developed a new method[5] for the simultaneous recording of the electrical and mechanical activity of both the pregnant and non-pregnant uterus. A characteristic tracing is illustrated by Fig. 1. Several hundred such model experiments in rabbits provided us with information which now allows us to predict rather closely the pattern of electrical activity from the pressure tracing. However, the tracing alone does not inform us about the direction in the spread of electrical activity. In order to obtain this information we had to adopt our new method of electro-uterography to the human uterus.

Fig. 2 illustrates schematically the technique of how electrical activity of the human uterus is recorded. The technique itself as applied to animals is described in detail in an earlier paper[5]. In women the insertion of the recording electrodes had to be modified. The myometrium was approached as if the patient would undergo amniocentesis[6]. Instead of traversing the myometrium the point of the needle (No. 18) was only immersed into its surface layers, allowing the insertion of an electrode through its lumen. The electrode was enamel-coated copper wire, 0·45 mm diameter, recoated at its naked tip (in contact with the myometrial cells) by silver or gold. The needle itself served as the indifferent electrode.

It is apparent that the electrical activity of parturient patients can be recorded, the tracings being very similar to those obtained by model experiments in rabbits. At present we are investigating the question of what additional information can be gained by the application of a set of electrodes, rather than one.

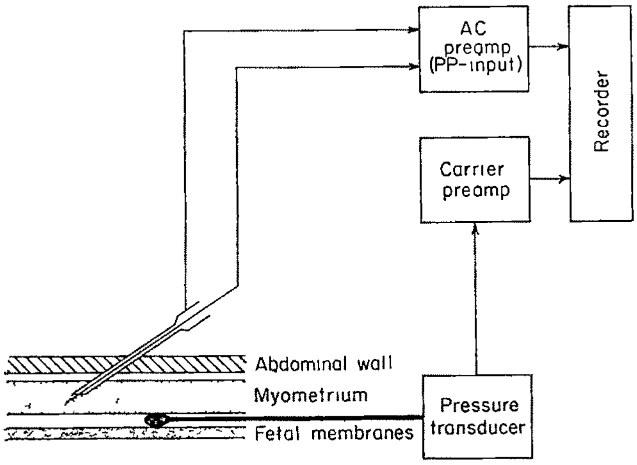

Fig 2. Schematic illustration of the technique, used in human patients. The needle inserted into the myometrium serves as indifferent electrode

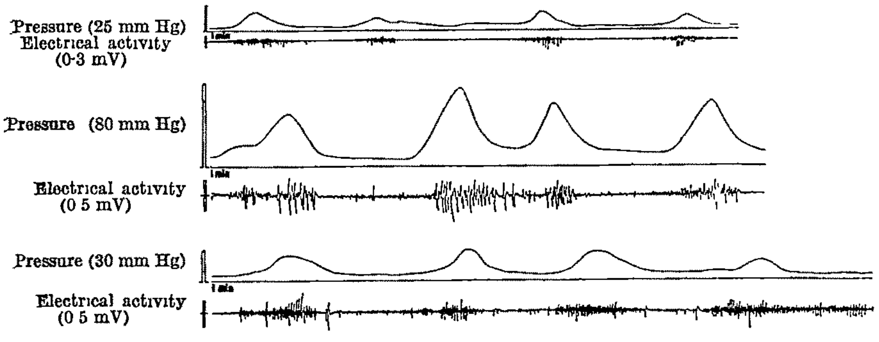

Fig 3. Electrical and mechanical activity of three patients in early labour. Note the similarity in the character of electrical activity of the rabbit and human uterus

In vitro Stimulation by Insulin of α-Aminoisobutyric Acid Transport in the Absence of Protein Synthesis

SINCE the demonstration by Kipnis and Noall[1] that insulin stimulates the accumulation of the non-utilizable amino-acid α-amino-isobutyric acid (AIB) by cells of the intact rat diaphragm *in vitro*, attempts have been made to relate this phenomenon to the action of insulin on protein synthesis. A review of the available evidence led Manchester and Young[2] to the conclusion that the action of insulin on accumulation of amino-acid by the diaphragm of the rat is probably limited to non-utilizable amino-acids and that it may represent an effect secondary to a direct stimulation of protein synthesis. In their view, AIB accumulation "can be regarded as filling the gap left by amino-acids used up in the synthesis of extra protein which occurs in the presence of insulin". The more recent observation[3] that insulin increases the transport of a number of naturally occurring amino-acids into muscle cells prompted us to re-examine the possibility that the effect of insulin on AIB accumulation may be a direct action of the hormone on an amino-acid transport system.

The conditions used for the investigation of AIB-^{14}C transport and amino-acid incorporation into protein in the 'intact' hemidiaphragm of the rat have been described in detail[4,5]. Briefly, normal female rats (Charles River strain) weighing 60–70 g were killed by dislocation of the cervical vertebræ, their diaphragms excised with rib cage attached and bisected through the central ligament and through the insertions to the xiphoid process and spine. The 'intact' hemidiaphragms thus obtained were incubated in Krebs bicarbonate buffer gassed with 5 per cent carbon dioxide and 95 per cent oxygen and containing glucose (10 mM). At the termination of incubation the diaphragms were dissected from surrounding tissue, blotted, weighed and the radioactivity of the tissue water and the purified proteins determined by liquid scintillation spectrometry. The extracellular space was measured by the distribution of insulin-1-^{14}C. Extracellular space of the tissue was determined for each control and experimental situation utilized in this investigation and the results expressed as the concentration ratio of AIB-^{14}C

$$\left(\frac{\text{c.p.m./ml intracellular water}}{\text{c.p.m./ml incubation medium}}\right)$$

Bovine insulin (Lilly *PJ*-4609, 23.8 U/mg) was added to the incubation medium at a concentration of 0.1 U/ml. Protein synthesis in the isolated diaphragm was blocked by the addition of puromycin[6] (500 μg/ml.). This concentration was chosen because it maximally depressed the incorporation of uniformly labelled ^{14}C-valine into diaphragm protein (Table 1). Similar findings have been obtained with ^{14}C-histidine, ^{14}C-alanine and ^{14}C-leucine in diaphragms of normal and hypophysectomized rats.

The results are presented in Table 2. It may be seen that puromycin at a concentration which essentially abolishes amino-acid incorporation into protein did not depress the accumulation of AIB in the intracellular compartment of control diaphragm muscle nor did it influence in any way the marked stimulation of uptake of AIB effected by the simultaneous addition of insulin to the medium.

Table 1. EFFECT OF PUROMYCIN ON THE INCORPORATION OF ^{14}C-VALINE* INTO PROTEIN OF 'INTACT' RAT HEMIDIAPHRAGM *in vitro*

	Time of incubation (min.)

* 0.1 mM (0.05 μc./ml.).
† Mean ± *S.E.* No. of observations in parentheses.

Table 2. EFFECT OF INSULIN AND PUROMYCIN ON THE ACCUMULATION OF ^{14}C-AIB* IN THE INTRACELLULAR WATER OF 'INTACT' RAT HEMIDIAPHRAGM *in vitro*

Additions		Time of incubation (min.)		
Insulin	Puromycin	90	120	180
		Concentration ratio		
–	–	1.48 ± 0.10 (12)†	1.60 ± 0.09 (13)	2.10 ± 0.20 (12)
–	+	1.53 ± 0.09 (6)	1.62 ± 0.19 (7)	1.81 ± 0.05 (6)
+	–	2.63 ± 0.09 (12)	3.55 ± 0.16 (12)	4.16 ± 0.17 (12)
+	+	2.50 ± 0.09 (6)	3.34 ± 0.22 (6)	4.11 ± 0.15 (6)

* 0.05 mM, 0.025 μc./ml.
† Mean ± *S.E.* No. of observations in parentheses.

These experiments clearly demonstrate that the stimulation by insulin of AIB accumulation in muscle cells of the isolated intact rat diaphragm is not secondary to the stimulation of protein synthesis and that it may represent a primary action of the hormone. Whether this conclusion is also applicable to naturally occurring amino-acids remains to be determined. It may be of interest that the stimulation of AIB transport by growth hormone in diaphragms of hypophysectomized rats is similarly not abolished by the action of puromycin[7].

This work was supported by a grant (*A*-5655) from the National Institutes of Health, U.S. Public Health Service. We thank Dr. M. A. Root of Eli Lilly and Co. for the gift of insulin.

Precocious Organic Iodine Secretion in the Blood by the Thyroid Gland

WHILE examining the variation in time of plasmatic PB^{131}I (normal human subject) after ingestion of an Na^{131}I as a tracer, we have found, in some cases, the existence of a radioactivity 'peak' during the first few hours after ingestion. The phenomenon is repeated, whatever the method of separation of the plasmatic proteins: precipitation with trichloroacetic acid, fractioning by ion-exchanger resin[1], or in a 'Sephadex' column[2]. Fig. 1 illustrates a typical case.

Assuming that the occurrence is not due to some form of artefact, it would appear logical to assume that it indicates the secretion of iodinated organic substances of

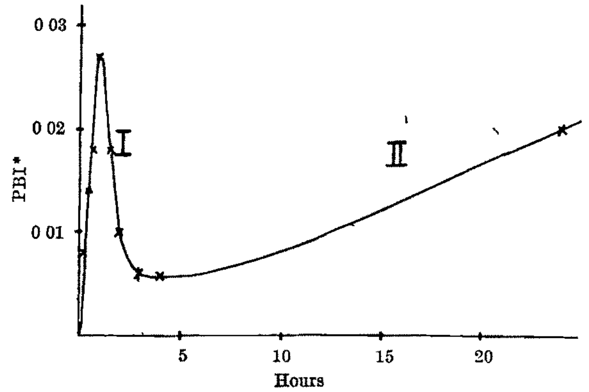

Fig 1

rapid metabolism (phase I) in addition to the usual hormonal secretion (phase II)

An argument in favour of this assumption is the effect on the occurrence of thyroid stimulating hormone and perchlorate, which conforms with the well-known effects of these agents on thyroid metabolism A further and stronger argument being the separation of a radioactive iodinated organic fraction, varying in concentration in the plasma with time, and in parallel with phase I of the curve, we have experimented on the rat, the demonstration involving the administration of too great a dose of radioactivity for a human subject

A typical experiment consisted of administering 40 μc by intraperitoneal injection and killing the rats in groups of three at intervals varying from the time of injection The curve in Fig 2*a* shows the variation of concentration of organic iodine in plasma, separated by ion exchanger resin, versus time Again, a curve is plotted which appears to demonstrate the existence of two phases of metabolism Fig 2*b* shows the same variation during a similar experiment, but after injection of 5 U H L thyroid-stimulating hormone 'Endopancrine' to each rat 1 h before administration of the iodine isotope

Comparison of curves in Figs 2*a* and 2*b* reveals the highly significant effect of the thyroid-stimulating hormone on the concentration of organic radioactive iodine in plasma, and particularly on the maximum appearing at about the third hour As already stated concerning the human subject, this appears to confirm the thyroid origin of phase I, and the possibility of the existence of an organic iodine secretion of rapid metabolism Chromatograms according to the Partridge method[3] have been carried out on the butanolic extract of sera obtained at various intervals after injection of the tracer Fig 3 is a radiochromatogram on a sample obtained after 3 h The presence of an iodinated fraction distinct from the iodide but with a very closed R_F may be noted On the contrary, chromatograms on samples obtained after 24 h reveal the usual iodinated components only—iodothyronine and iodide—but the fraction with an R_F close to that of the iodide has completely disappeared

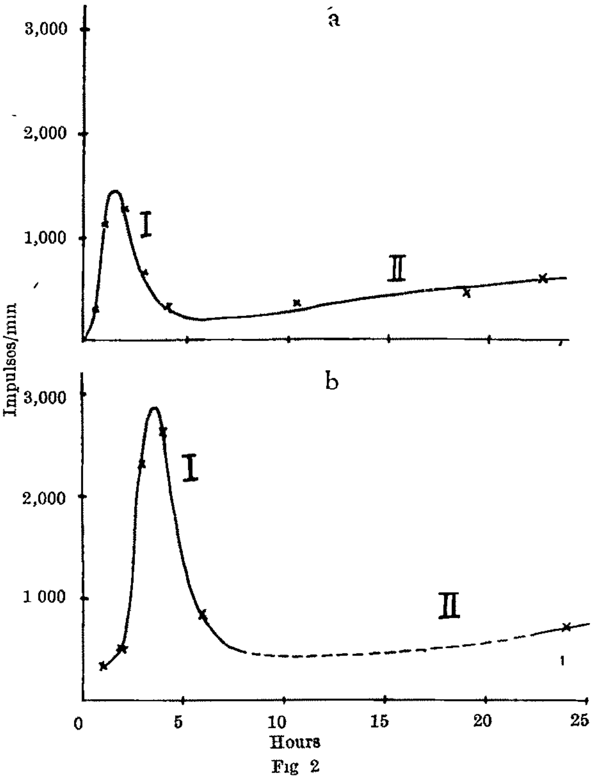

Fig 2

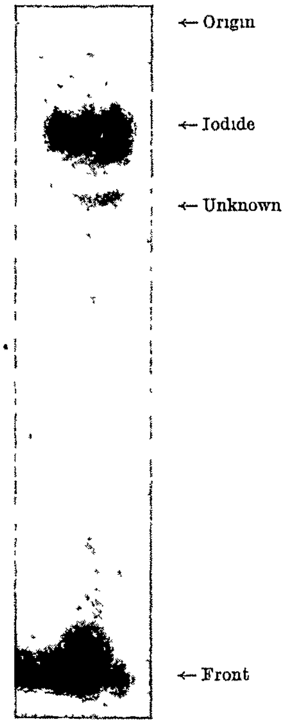

Fig 3

Taken together, these experimental results appear to us to indicate the existence of secretion by the thyroid of iodinated organic substances renewed much more rapidly than the hormones What is the nature of these substances, and what is their physiological role ? Regarding the first question, our preliminary investigation seems to indicate that the substances are iodinated peptides of thyroid origin

The existence of rapid metabolism in addition to the usual metabolism of thyroid hormones could perhaps explain the apparent contradictions liable to appear in the results obtained with iodine-127 and iodine-131, in the case of samples obtained after the 24 h

Hyperlipidæmia : a Cause of Decreased Oxygen Saturation

THE induction of hyperlipidæmia by the intravenous infusion of a fat emulsion in human beings produces a fall in arterial oxygen saturation While the phenomena were observed earlier by Kuo[1] in human beings and in dogs by Stutman[2] and Cain[3], the observations have not been extremely pursued nor has the mechanism of such a decrease in arterial oxygen saturation been fully explained

Eleven male volunteer prisoners (age range 20–30 years) were investigated in the supine fasting state An indwelling Cournand needle was placed in the brachial artery and control blood samples taken for blood oxygen content and capacity measurements All measurements were carried out by the manometric method of Van Slyke and Neill[4]. 500 ml of fat emulsion ('Lipomul' supplied by courtesy of the Upjohn Co , Kalamazoo, Michigan) containing 15 per cent cottonseed oil was infused into an anticubital vein over a 2-h period The infusion of 500 ml of 'Lipomul' was found to raise indirect triglyceride-levels from a control range of 2 2–7 m equiv /l to 43 m equiv /l and TEFA levels from 250–400 mg to 1.500 mg/per cent Samples for arterial oxygen saturation were obtained at the end of the infusion period The addition of 'Lipomul' in appropriate quantities to blood samples was shown not to interfere with the determination of blood oxygen by the manometric technique The increase in fat concentration does, however, alter the amount of physically dissolved oxygen which must be subtracted from the oxygen capacity and content before calculating the oxygen saturation The solubility coefficient for oxygen in cottonseed oil is approximately 5 times that in blood[5] The addition of 500 c c of 'Lipomul' is equivalent to the addition of 75 c c of cottonseed oil All oxygen measurements from the bloods containing 'Lipomul' were corrected for the amount of physically dissolved oxygen which would have normally been present plus the additional amount which was present because of the added fat before saturation values were calculated

Table 1 EFFECT OF 'LIPOMUL' ON OXYGEN SATURATION

B J	96 0	91 8	—
D W	96 2	90 3	—
A H	97 5	90 3	—
Average	96 1	91 9	96 1

From Table 1 it may be seen that arterial oxygen saturation fell from an average of 96 1 to 91 9 per cent following the production of hyperlipidæmia In order to help determine if this fall in oxygen saturation was caused by a shunt or by a diffusion defect, the subjects were given 40 per cent oxygen to breathe for 5 min and arterial samples again obtained The rise in saturation to pre-infusion levels would indicate that the fall in oxygen saturation might well be due, at least in part, to a diffusion defect Preliminary measurements of pulmonary diffusing capacity for carbon monoxide by the single breath method of Ogilvie *et al* [6] on 4 of the subjects before and after 'Lipomul' indicate a decrease from a control value of 35 6 ml CO/min/mm mercury to 30 2 ml CO/min/mm mercury in the post-infusion period These observations do not rule out the possibility of changes in ventilation-perfusion relationships in the lung being a contributing factor in the production of the arterial oxygen unsaturation The failure of the saturation values to rise above the pre-infusion levels does indeed suggest that some degree of shunting may be present

The significance of these observations particularly as they relate to the deprivation of oxygen to cellular metabolic systems represents an intriguing investigative field at the present time While it is widely appreciated that hyperlipidæmia may be associated with atherosclerosis and profound changes in the blood coagulation systems, the establishment of significant decreases in arterial oxygen saturation in normally occurring hyperlipæmia presents a controversial investigative problem

Development of Bradycardia during Submersion of the Duck

SOME mammals and birds display structural and functional adaptations which permit them to endure submersion asphyxia for extended periods of time Among the adjustments to submersion of diving animals, those concerned with the cardiovascular system are the most frequently described The most conspicuous and easily observable features displayed during submersion are a sudden onset of apnœa followed by a striking bradycardia

The receptor sites and the quality of the stimuli which bring forth the adjustments observed during submersion are unknown It has been alleged that the actual immersion under water must play a dominant part in the afferent reflex chain, and that naturally diving animals are endowed with special mechanisms for reacting to this stimulus[1]. On the other hand, some authors have advocated that the mechanism mobilized to combat asphyxia is no different in quality in diving animals from what is found in typical non-diving animals[2]

The experiments described here are an attempt to disclose whether water immersion as such is a triggering factor to the submersion bradycardia in the domestic duck

Domestic ducks, *Anas boscas*, were tracheotomized, and catheters for intravascular pressure measurements were introduced in the brachial artery and vein The operative procedures were performed under local anæsthesia. The animals were resting in upright, normal positions during the entire experimental period This precaution was executed carefully to avoid disturbances of the breathing pattern or the vestibular mechanisms Artificial ventilation using various gas mixtures was applied through the tracheal cannula The central arterial and venous pressures were fed into Statham pressure transducers and recorded on a Sanborn four-channel recorder Diving was simulated by immersion of the animal's head in a water container, taking care to retain the upright position of the animal during the immersion period

Fig 1 depicts cardiac cycle-length (C C L) (each point represents the average in a 10-sec period) and arterial

(A P.) and venous (V P) pressures during an experiment involving the following steps The animal was artificially ventilated with air At each inspiration an elevation of the central venous pressure occurred Prior to point *A* is seen the normal resting values of the parameters measured At point *A* the animal was blindfolded by a gentle grip with one hand around the animal's head No undue pressure was exerted and the beak and nares remained uncovered The blindfolding is seen to introduce a moderate change in cardiac cycle-length with minor changes in arterial and venous pressure-levels If anything, the conspicuous sinus arhythmia seen in many birds became particularly prominent The bradycardia amounted to about a 20–30 per cent reduction in frequency. This initial bradycardia could easily be induced by a number of stimuli involving touching of the animal's head or bending its head forward.

At point *B* the animal's head was held slightly forwards, simulating exactly the position of the head during the immersion in water There was no change in cardiac rhythm

At point *C* the animal's head was submerged There was a slight transient increase in heart rate; but the frequency soon levelled off at the value characteristic of the pre-immersion period

At point *D* the artificial respiration was stopped as apparent in the cessation of the sinus arhythmia and the respiratory fluctuations in the venous pressure record From point *D* on, a gradually increasing bradycardia is seen to appear The development of the bradycardia was dependent on a number of factors which are being subjected to further investigation The cardiac slowing became particularly prominent after a period of 40–50 sec of arrested breathing and could amount to a prolongation of the cardiac cycle by a factor of four when the animal displayed muscular efforts involving the thoracic musculature The importance of the muscular activity was amplified as curarization of the animal prevented the conspicuous bradycardia seen otherwise We believe that receptors sensitive to mechanical distortion located within the thoracic cavity or in the respiratory musculature proper are important in the development of the bradycardia during submersion asphyxia No effect of immersion in water was detectable after a slight initial bradycardia had already been established by blindfolding or a number of other unspecific stimuli Our experiments therefore disagree with the idea that immersion in water *per se* plays any major part in the development of bradycardia during submersion of the duck

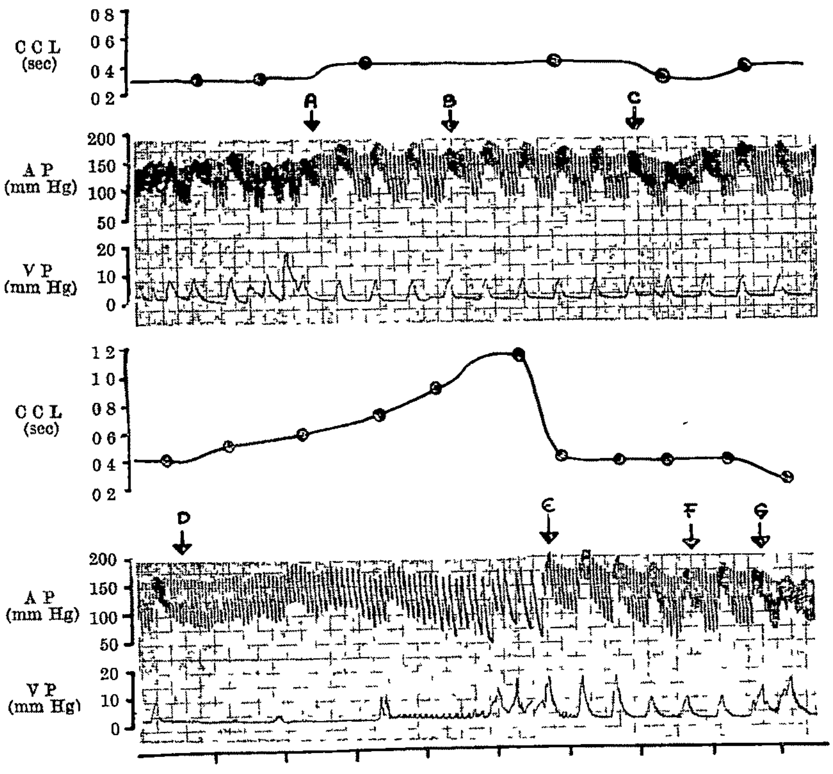

Fig 1

At point *E* the artificial respiration was resumed The heart frequency returned promptly to the values recorded before cessation of the breathing movements At point *F* the animal was taken out of water with no change in cardiac rhythm At point *G* the animal was released from the blindfolding. This act increased the heart frequency further and completed a reversible cycle, giving back the initial frequency that prevailed before onset of blindfolding (point *A*)

PHARMACOLOGY

Salicylate and Increased Vascular Permeability due to Hyaluronidase

Much work has been carried out on the action of sodium salicylate on the hyaluronic acid hyaluronidase system, and some of it is contradictory In fact, Guerra[1] pointed out that salicylate inhibits the action of hyaluronidase, and on the basis of this, he suggested this inhibition would explain the action of the salicylate in rheumatic diseases These results were completely or partially confirmed by others[2–6]

On the contrary, no inhibition of this enzymatic system by the salicylate could be demonstrated by other workers[7–12] Furthermore, the hyaluronidase was found capable of increasing the atheromatous lesions of rabbits fed hypercholesterolic diet[13–15]

On the basis of the foregoing results, 22 female rabbits were fed a high cholesterol diet (0 2 g/kg a day *per os*) in order to demonstrate a possible inhibiting effect of salicylate on the action of hyaluronidase At the 44th day after the beginning of the treatment, 12 animals were given 15 per cent solution of salicylate intraperitoneally at the dose of 0 5 g/kg a day for 10 days At the 54th day after the beginning of the experiment, 6 of the 10 cholesterol fed animals and 6 out of the 12 cholesterol + salicylate fed animals received twice 1,000 viscosimetric units of testicular lyophilized hyaluronidase diluted into 3 ml of saline solution The other animals were given saline solution only All the animals were killed 30 days later

The entire aortas, previously fixed in formalin and stained with sudan III, were grossly and independently observed by 4 persons following a suitable scheme Afterwards the specimens were cut using the freezer microtome and the sections restained with sudan III

Both macroscopically and microscopically we observed (*a*) more severe atheromatous lesions in the animals treated with hyaluronidase than in those of the other groups, as already described by Cali and Seifter[13–15], (*b*) a slight inhibition of the hyaluronidase by sodium salicylate in the animals treated with cholesterol, hyaluronidase and sodium salicylate, whereas no significant variations were observed in the animals treated with cholesterol and sodium salicylate

Therefore, we believe it may be assumed (*a*) that high doses of sodium salicylate slightly inhibit the hyaluronidase only when the hyaluronic acid–hyaluronidase system is turned towards the hyaluronidase, as in the animals treated with cholesterol and hyaluronidase; it would be advisable to examine the relationship between this effect and the dose of salicylate, (*b*) that it is possible to confirm only in part what Guerra[1] found in his experiments, (*c*) that there is not sufficient evidence to state, as Guerra did, that salicylate is effective in rheumatic diseases because of its antihyaluronidase action It might be considered this is only a part of the therapeutic efficiency of this drug In this respect, on the other hand, it has been recently pointed out[16–19] that other substances of the bradykinin group are important in the pathogenesis of rheumatic diseases and that sodium salicylate completely inhibits the action of these substances

Elevation by Propynylamines of Rat Tissue Norepinephrine-levels and Reserpine Antagonism in Mice

The hydrochlorides of 2-propynylamine, di-2-propynylamine, and tri-2-propynylamine were tested in several systems for monoamine-oxidase inhibition The 2-propynylamines were supplied through the courtesy of Dr Alfred Bader of the Aldrich Chemical Co

Norepinephrine-levels were determined in the pooled brains and hearts of groups of 5 rats each injected intraperitoneally with 10 mg/kg and 40 mg/kg of 2-propynylamine hydrochloride once daily for 4 days The tissues were extracted in duplicate by the procedure of Shore and Olin[1] and norepinephrine determined by the method of Von Euler and Floding[2] using a spectro-photofluorometer The 10 mg/kg dose of 2-propynylamine hydrochloride elevated brain- and heart-levels of norepinephrine to 151 per cent (146–156) and 122 per cent (114–130) of the levels found in control animals The 40 mg/kg dose raised brain and heart norepinephrine-levels to 185 per cent (170–200) and 130 per cent (128–133) of the control values

Table 1 ANTI-PTOTIC AND ANTI-EXTENSOR SEIZURE EFFECTS OF 2-PROPYNYLAMINES IN MICE GIVEN RESERPINE

Compound	Dose (mg/kg, intraperitoneal)	Time before reserpine	Degree of ptosis	mg/kg metrazole required to cause seizures (mean ± *S E*)
None	—	—	0	12 ± 1 0
Reserpine alone	4	—	4	5 8 ± 0 8
+ 2-propynylamine hydrochloride	50	9 days	2 3	11 5 ± 2 2
	50	2 h	0 8	13 8 ± 0 5
	25	2 h	3 4	8 8 ± 3 5
+ Di-2-propynylamine hydrochloride	50	2 h	2 4	12 5 ± 2 8
	25	2 h	3 9	5 3 ± 0 5
+ Tri-2-propynylamine hydrochloride	100	2 h	3 1	11 0 ± 2 0
	50	2 h	3 8	7 8 ± 1 0

The monoamine-oxidase activity of the propynylamines was examined in mice by their ability to reduce the reserpine-induced ptosis and to antagonize the facilitatory effect of reserpine on tonic-extensor seizures[3] Groups of 5 mice each were given the propynylamine compounds by intraperitoneal injection and 2 h or more later were given 4 mg/kg of reserpine, in 5 per cent ascorbic acid solution, by intraperitoneal injection One group of mice without drug treatment and one group given reserpine alone were used in each experiment as controls A 0 5 per cent solution of 'Metrazol' was used to produce tonic-extensor seizures by intravenous infusion Table 1 shows the activities of the 2-propynylamines in both tests At the 50 mg/kg dose-level of 2-propynylamine the anti-reserpine activity, as measured by the 'Metrazol' test, lasted for 9 days Di-2-propynylamine and tri-2-propynylamine both had anti-reserpine activity but were less active than 2-propynylamine The 2-propynylamines alone did not cause any marked retraction of eyelids or produce an anti-convulsant effect on tonic-extensor seizures at the doses used

2-Propynylamine is a potent compound in raising rat tissue norepinephrine-levels, furthermore, 2-propynylamine antagonizes the effects of reserpine in mice

HÆMATOLOGY

Absence of Lysolecithin Formation in C'_3-deficient Rabbit Serum

Recently, Fischer and Haupt have shown[1–3] that the activation of complement in human, guinea pig, rabbit, and pig serum is paralleled by an increase in lytic activity due to an increase of lysolecithin In these experiments complement was activated by the addition of soluble antigen–antibody-complexes or by the addition of heat-aggregated human γ-globulin Complement activity was determined using sensitized sheep erythrocytes, while the lytic activity of lysolecithin was determined in lipid extracts of the same sera by the method of Schubothe and Fok[4] (see also legend to Table 1)

Further evidence for the dependence of lysolecithin formation on the presence of whole complement might be obtained by demonstrating that rabbit sera lacking C'_3 are unable to form lysolecithin

A strain of C'_3-deficient animals (*Freiburg R 3-Stamm*) was described recently and investigated by K and U Rother[5,6] In the hæmolytic system serum of C'_3-deficient animals behaves in the same way as does rabbit serum depleted of C'_3 by treatment with 'Zymosan' Complement activity can be restored by adding any preparation which contains C'_3

Table 1

		Complement activity (50% hæmol units)	Lytic activity of serum extracts (% of total hæmolysis)	Δ lytic activity (%)
Experiment No 1 (rabbit No 1)	Normal rabbit serum	35	14	
	Normal rabbit serum + γ-globulin	0	43 5	c 300
	C'_3-def -rabbit serum	0	16	
	C'_3-def -rabbit serum + γ-globulin	0	16	0
Experiment No 2 (rabbit No 2)	Normal rabbit serum	30	12	
	Normal rabbit serum + γ-globulin	0	23 2	c 100
	C'_3-def -rabbit serum	0	14 6	
	C'_3-def -rabbit serum + γ-globulin	0	14 6	0
Experiment No 3 (rabbit No 3)	Normal rabbit serum	15	24	
	Normal rabbit serum + γ-globulin	0	45 5	c 100
	C'_3-def -rabbit serum	0	24 6	
	C'_3-def -rabbit serum + γ-globulin	0	27 0	c 10
	C'_3-def -serum + *R*1,2,-serum *	8	26 2	
	C'_3-def -serum + *R*1,2-serum + γ-globulin	0	40 0	c 50
	C'_3-def -serum + C'3(pig) †	5	27 8	
	C'_3-def -serum + C'3(pig) + γ-globulin	0	40 6	c 50

* Serum heated at 56° for 25 min

† According to Leon *et al* (ref 8)

The sera of normal and C'_3- deficient animals were incubated simultaneously for 30 min with 1/10 vol of a 5 per cent solution of heat-aggregated (56° C, 30 min) human γ-globulin (Behringwerke, Marburg) Complement activity was determined using standard techniques (ref 7) The lytic activity of serum-extracts (obtained by extracting serum with 20 vol of ethanol/ether 3 1) was estimated in an apparatus originally designed for the determination of erythrocyte fragility (ref 4) The percentage of total hæmolysis obtained under standard conditions is given in the table

The results of three experiments are shown in Table 1

The results show an increase in lysolecithin activity in normal sera after incubation for 30 min at 37° C with aggregated γ-globulin No increase occurred in *R* 3-deficient sera The addition of C'_3 preparations to the deficient serum (experiment No 3) restored some of the complement activity and some of the ability to increase the level of lysolecithin

These results give additional support to the lysolecithin hypothesis[1-3,9] of complement action

A Hæmagglutinating Property of Mouse Serum for Human Red Blood Cells

HETEROAGGLUTININS for human red cells have been reported in various species[1,2] Quantitative differences between males and females in a globulin fraction of mouse serum has recently been reported[3] Stimpfling has described a quantitative difference in the anti-sheep and anti-chicken heteroagglutinin content of normal sera from *C*57 *BL*/6 *Sn* mice[4]

An examination of mouse sera from different inbred strains has shown the sera of some strains to agglutinate strongly most samples of human A blood group cells while O and B blood were not agglutinated in the same proportion Only the results of sera from strains *B*10 and *C*3*H* will be reported here

The agglutination technique consisted in mixing, in a slide, a drop of undiluted mouse serum from a pool obtained from adult males or females with a suspension of three-times washed human red blood cells from healthy blood bank donors The reaction occurs in 1 or 2 min at room temperature and can be observed macroscopically

The strength of the agglutination was arbitrarily classified macroscopically as + + + + if all cells were stacked in one clump, + + + when the cells were all agglutinated in several clumps , + + and + when free cells were present, and − when no red cell agglutination was observed Weak and doubtful reactions were read microscopically (× 30)

A test made separately of male and female sera from mice 6–8 months old gave an unexpected sex difference female sera from *B*10 animals strongly agglutinate human A blood group cells while sera from males of this same strain did not agglutinate them to any appreciable extent This difference was not found in male versus female sera of *C*3*H* mice

The agglutination effected by sera from *C*3*H* mice was usually weaker than that obtained with *B*10 sera No difference was observed between human male and female red blood cells The agglutinating property could be made to disappear specifically from *B*10 female sera by absorbing it with three-times washed male tissues (liver plus spleen), from *B*10 or with A blood group red cells

Tissues from male or female *C*3*H* animals did not absorb *B*10 female heteroagglutinins It thus seems that the reaction of female *B*10 sera is specific Two out of thirty-three *B*10 male sera gave a positive though very weak reaction (± or less) with A blood group cells

A sex difference in agglutination was also observed when B and O cells were tested with *B*10 male versus female sera The differences, however, were not so marked as with A cells and the reaction of both male and female

Table 1 HETEROAGGLUTINATION OF HUMAN RED CELLS OF BLOOD GROUPS A, B, AND O BY NORMAL MALE AND FEMALE SERA FROM STRAINS *C*57, *BL*/10 AND *C*3*H*

Blood groups of donors	Mouse serum from strains *C*57 *BL*/10*		*C*3*H*	
	M	F	M	F
A	0/22†	22/22	22/22	21/22
B	9/20	17/20	19/20	17/20
O	4/24	21/24	24/24	23/24

* *B*10 males versus females = $P < 0\ 50$ for group B red blood cells
$P < 0\ 01$ for group O red blood cells

† $\frac{\text{No of samples agglutinated}}{\text{Total No of bloods tested}}$

Table 2 INCREASE IN NORMAL HETEROAGGLUTININS AGAINST HUMAN BLOOD GROUP RED BLOOD CELLS WITH INCREASING AGE OF *B*10 FEMALES

Human A group red blood cells	Hæmagglutination of A red blood cells by *B*10 female sera of ages* Months 1	2	3	4	6
No 5409	±	± +	+ +	+ +	+ + + +
5433	±	± +	+ +	+ + +	+ + + +
5432	±	+	+ +	+ + +	+ + + +
5365	±	+ +	+ +	± + +	+ + + +
5473	±	+ +	+ +	+ +	+ + + +

* The strength of the agglutination was arbitrarily classified macroscopically as + + + + if all cells were stacked in one clump, + + + when the clumps were all agglutinated in several clumps, + + and + when free cells were present and − (negative) when no red cell agglutination was observed

sera with O and B cells was weaker than that observed with A red cells (Table 1)

A study of individual sera from *B*10 females showed a marked age effect on the strength of the agglutinating properties Sera from young females gave weak but consistently positive reactions with human A cells while sera from six months old females gave +++ to ++++ reactions with the same human red blood cells With the exception already mentioned, *B*10 male sera of all ages were negative This increase in agglutinin content with age suggests these agglutinins to be induced by subclinical infections with bacteria carrying antigenic structures related to the ABO system A similar increase in titre of natural heteroagglutinins for red cells and bacteria with age has been described[4,5]

The findings reported here can be interpreted to show a qualitative difference in heteroagglutinating capacity of normal female versus male sera The existence of occasional (2/33) weakly (±) reacting males may be due either to an extreme case of quantitative sex variation or else to technical artefacts The difference between sera from *C3H* and *B*10 strains is striking These strains also differ in that *B*10 females reject male skin grafts while *C3H* females accept them This, the so-called 'Eichwald-Silmser effect', depends on a *Y*-chromosome determined incompatibility between the sexes[6] The possibility remains of a relationship between the male antigen and the human blood group antigen reacting with *B*10 female sera Quantitative differences could be related to an heterotic effect of the *X*-chromosome in double dose in females or to an enhanced antibody production by œstrogen stimulation

Effects of Surgical Procedures on the Appearance of Slow α_2-Globulin

IT has recently been shown that a variety of conditions mostly related to growth or tissue synthesis evoke a protein in the sera of rats which is not demonstrable in the sera of healthy, non-pregnant, adult rats This material is termed slow α_2-globulin (*SA*$_2$*G*) since, in paper electrophoresis, it exhibits the mobility typical of α_2-globulin, whereas in starch-gel electrophoresis it moves more slowly than both the β-globulin and a slow α_1-globulin[1,2] *SA*$_2$*G* can be demonstrated during prenatal[2–4], postnatal[3–6], and neoplastic[3–8] growth, during pregnancy[3,4,6] and during liver regeneration following partial hepatectomy or carbon tetrachloride poisoning[9,10] While these conditions all involve considerable tissue synthesis, *SA*$_2$*G* also appears in several situations where little or no obvious growth occurs lactation[3,4], tight abdominal bandaging[7], after Caesarean section with retention of a single placenta[6], and in various ill-defined but possibly infectious disease states[6,10]

Since, as already noted by Beaton *et al* [6], the development of new tissue does not appear to be an absolute requirement for the appearance of *SA*$_2$*G*, we undertook to determine the presence or absence of *SA*$_2$*G* after a variety of surgical procedures involving wound healing and, in some but not all cases, compensatory hyperplasia Methods used included unilateral renalectomy and adrenalectomy, *in situ* unilateral ligation of the kidney and adrenal gland, splenectomy, amputation of a forelimb, partial exsanguination, implantation of homologous minced kidney and sham abdominal surgery Only after certain of these treatments did *SA*$_2$*G* appear in the serum.

The animals used, their treatment and the methods of obtaining sera were as previously described[4] Combined unilateral renalectomy and adrenalectomy, splenectomy and combined unilateral ligation of kidney and adrenal without their removal were performed through lateral incisions For the kidney implant operations, a kidney from a donor rat of the same inbred strain was minced with scissors under sterile conditions until the pieces were 2–3 mm on a side They were then implanted into the abdominal cavity through a small ventral incision Surgical sham operations were performed as previously described[10] Limb amputations were performed near the middle of the ulna and radius of the right forearm After a purse-string suture was placed through the skin around the limb a few millimetres proximal to the prospective level of amputation, the skin and muscles were cut, the bones severed with scissors, the purse-string suture tightened and tied In all other operations, the muscles were approximated with silk and the skin closed with wound clips Partial bleedings were performed by severing the rat's tail and collecting 20 ml blood/kg body-weight Bleeding was stopped by a tourniquet and/or cautery These procedures were performed under ether anæsthesia At designated intervals after operation, blood was collected from the tail vessels or by heart puncture Vertical starch-gel electrophoresis was performed by the method of Smithies[11], with minor modifications as previously described[4].

Care must be taken during the slicing of the starch plate not to allow the two newly cut portions to touch each other Should they touch, a small amount of protein may be transferred or 'off-printed' from one to the other Unless the two halves touch exactly in register, a new, artefactual band may be produced This is especially likely in the case of a protein giving a narrow, intense band, for example, slow α_1-globulin The spurious band may be distinguished from a true band by making a cut into the starch parallel to the axis of migration and

examining the depth of the bands within the starch: a spurious band will be very shallow, a true band will extend all or most of the way through the starch.

The results obtained are shown in Table 1. In none of the surgical procedures under consideration is there any regeneration of the affected organ in the sense that such regeneration occurs after partial hepatectomy. However, in all but the minced kidney implantation, sham surgery and limb amputation, considerable compensatory hypertrophy or hyperplasia may be expected (see, for example, ref. 12). It is clear from the results obtained that SA_2G is demonstrable in all those conditions involving compensatory growth except the partial exsanguination. The failure of SA_2G to appear after considerable loss of blood might be attributable to: (*a*) failure to remove sufficient blood; (*b*) small amount of wound healing called forth; (*c*) the attributes of a system which produces massive quantities of new tissue at all times, even in the absence of experimental manipulations. In some experiments designed to test the first hypothesis, large quantities of blood were removed once or repeatedly, without, however, evoking a demonstrable production of SA_2G. In the minced kidney implant operation and in some other manipulations at present being used in this laboratory, little wound healing is called forth yet SA_2G becomes readily demonstrable. Hence, the third hypothesis seems most likely at this time. The failure to evoke demonstrable SA_2G by partial bleeding also indicates that loss of blood at surgery is not the effective factor in the other surgical procedures. Compensatory growth of certain organs may, therefore, be one of the stimuli capable of calling forth the demonstrable production of SA_2G.

That conditions other than those leading to some type of growth can bring about the production of demonstrable SA_2G is shown by the frequent or occasional appearance of SA_2G after limb amputation, sham surgery or implantation of minced kidney. In view of the diarrhœa which is often found occurring in the rare cases of spontaneously SA_2G-positive control rats[6,9], and the ever-present possibility of wound infections, it is suggested that inflammatory or infectious disease may be a possible evocating agent. The presence of SA_2G in all rats two days after the implantation of minced kidney tissue and in the majority of rats four days after such implantation may be due to a stimulation, by products of tissue breakdown, analogous to that due to infection. That tissue breakdown can bring about an increase in α_2-globulin (but not necessarily slow α_2-globulin) in man has been known for some time[13]. Finally, it does not appear that mere surgical shock can lead to the production of demonstrable SA_2G since many rats subjected to limb amputation or sham surgery do not exhibit any SA_2G.

This work was supported in part by grant *GB*-347 from the U.S. National Science Foundation.

The Cl^a(Caldwell) Antigen: a New and Rare Human Blood Group Antigen related to the *MNSs* System

Two unrelated families have been found to demonstrate the inheritance of a new and rare red cell antigen, the specificity of which appears to differ from that of all other antigens so far described. It is proposed that the new antigen be named Cl^a(Caldwell). The close genetical linkage of Cl^a to the *MNSs* system has been established. In the two families here reported the coupling of Cl^a is with *Ms* throughout.

The propositus, Mr. Caldwell, had donated blood on six occasions, each time being grouped as O. On testing his seventh donation it was found that his red cells were weakly agglutinated by the anti-B grouping serum in routine use. Caldwell's cells were not polyagglutinable, nor were they agglutinated by any of a battery of high-titre anti-B sera known to be potent in detecting an 'acquired' B antigen[1], nor by a panel of high titre anti-A+B (group O) sera.

Initially we tested 11,000 random donors of all ABO groups in the West of Scotland, but no other Cl(a+) was detected. However, by chance, a second example of the Cl^a antigen was encountered in a cord blood specimen. The cells of Baby Gil. were agglutinated by the routine anti-B grouping serum, but not by an anti-A+B (group O) serum. The infant was in fact group O and Cl(a+). It was established by cross-absorption and elution tests that the Caldwell and Gil. antigens were identical.

Evidence from two generations of the Caldwell family and from four generations of the Gil. family indicates that the Cl^a antigen is the regular expression of the heterozygous state of an autosomal allele. The Gil. Cl^a can by deduction be traced back for 6 generations to an Irish woman born in Ulster about 1830. She must have transmitted her Cl^a to the child of each of her two marriages, so that to-day 27 of her living descendants are known to be Cl(a+). As there is not complete linkage of Cl^a with the *ABO*, *Rh*, *P*, *Kell*, *Duffy* or *Secretor* loci, it can reasonably be taken that the new antigen is not controlled by any of them. However, when the Gil. family data are analysed with respect to *MNSs* and Cl^a it becomes apparent that there are no certain recombinants and 12 certain non-recombinants between *Ms* and Cl^a. That such a finding is due to chance has a probability of 1 in 2^{12}, that is, 1 in 4,000. In addition, the existence of a further 30 almost certain non-recombinants confirms the closeness of this observed linkage. In the Gil. family the absence of a recombinant makes it impossible for us to decide whether Cl^a is part of, or linked to, the *MNSs* system. Cl^a must certainly now be considered as yet another of the rare antigens to be associated with the *MNSs* system in some manner.

Dr. T. E. Cleghorn has confirmed our findings or shown independently that the Cl^a antigen is not serologically identical with the following antigens which are known to belong to the MNSs complex—Hu, He (ref. 2), Mi^a, Vw (ref. 3), Mu(Murrell) (ref. 4), St^a(Stones), Ri^a(Ridley) (ref. 5), Vr (ref. 6), Mt^a (ref. 7) and Mg (ref. 8). The antigen does not appear to be similar to Mg; for example, there are no unexpected dosage effects observable in comparative titrations of Cl(a+) cells against anti-M, -N, -S, or -s sera. However, we have not yet encountered NN Cl(a+) or SS Cl(a+) bloods, and hence have not been able to test them for dosage. Such groupings would have been immediately indicative of recombination in the Gil. family.

Tests (again largely performed by Dr. T. E. Cleghorn) have also excluded identity of the Cl^a antigen with other rare or "private" antigens—C^w, C^x, E^w, V, VS, Bi, Be^a, Bp^a(Bishop) (ref. 9), Bu^a(Boisvert) (ref. 10), By, Donna, Good, Ho, Kp^a, Levay, P^k, Radin-Fleming (ref. 11), Stobo (ref. 12), Sw^a, Tr^a(Traversu) (ref. 9), Wb (ref. 13), Weil, Wr^a, Chr^a, Yahuda (ref. 9), Pritchard (ref. 9), Evans (ref. 14), Hunt (ref. 15), Kennedy (ref. 16) and Go^a (Gonzalez) (ref. 17). Three adult Cl(a+) persons have given normal adult I reactions, while 3 strong anti-Cl^a sera have contained no appreciable anti-i. Cl(a+) cells gave normal positive reactions with anti-Vel, -Ge, -U, -H, -Tj^a, with sera from 'Bombay' and D--/D-- persons, with potato lectin and with human 'D-like' antibody (ref. 18).

Though the Cl^a antigen is, at least in Baby Gil., well developed at birth, there is no evidence of it having been the cause of hæmolytic disease of the new-born in these two families under investigation. The 5 Cl(a−) mothers of Cl(a+) children have no detectable anti-Cl^a in their sera. Seventeen examples of saline-agglutinating anti-Cl^a were recognized in a series of 4,083 random donor sera of all ABO groups, that is, an incidence of 1 in 240 (0·42 per cent). Dr. T. E. Cleghorn found 7 examples of anti-Cl^a in 1,243 random South London donors.

Our anti-Cl^a sera have been apparently of natural origin. All had their optimal temperature of reaction at 4° C or at 12° C, none reacting at 37° C. In keeping with the findings of others[19] regarding the action of enzymes on antigen–antibody reactions within the *MNSs* system, the presence of bromelin, ficin, papain or trypsin was found to inhibit the Cl^a–anti-Cl^a reaction.

Finally, it is interesting to note that at an early stage of the investigation Cl(a+) cells were found positive with a South London anti-B serum, 'Easter', which Dr. I. Dunsford had shown to react with a Sheffield group O donor. Subsequent cross-absorption tests demonstrated that 'Easter' serum contains anti-Cl^a in addition to the antibody against the cells of the Sheffield donor.

We thank Dr. J. H. Renwick, Genetics Department, University of Glasgow, for collecting numerous blood samples for us, and for his guidance with the linkage studies. We also thank Dr. T. E. Cleghorn, South London Blood Transfusion Service, for performing many of the tests involving rare antigens and antibodies, and Dr. R. Sanger, Dr. I. Dunsford, Dr. M. C. Huth, Dr. M. Metaxas and Miss van der Hart for their co-operation.

HISTOCHEMISTRY

Acid-buffered Acetone as a Fixative for Enzyme Cytochemistry

ALTHOUGH acetone has been recommended as a fixative in the histochemical study of enzymes in tissue sections[1,2], there have been but few reports on the use of this fixative in the examination of blood films and related preparations.

In the work recorded here, a variety of hydrolytic enzymes were demonstrated on smears of blood, bone marrow, transudates, exfoliated cells, and tissue culture cells, as well as on organ imprints, using a fixative 60 per cent acetone buffered to pH 4·2 with citrate. Brief fixation (20–30 sec) at room temperature resulted in good preservation of cellular morphology, in most cases of a quality approaching that seen with methanol fixation. The cells showed no tendency to wash off the slide even when fresh and when placed under a vigorous stream of water.

The following enzymes were successfully demonstrated: alkaline and acid phosphatases, esterase (acetyl and chloroacetyl naphthols) using azo dye coupling techniques, peroxidase (benzidine method) and dopa oxidase.

The degree of activity as judged by intensity of dye deposition was greater than or equivalent to that seen with other fixative procedures. Except for acid phosphatase, most preparations exhibited sites of activity and intensity of dye formation similar to that seen on unfixed smears. Acid phosphatase was found primarily in myeloid cells and platelets with weak activity seen in monocytes and lymphocytes, although higher activity was demonstrated in unfixed smears. When 'Naphthol *AS-D*-chloroacetate'[3,4] was used as a substrate, activity was demonstrated in monocytes and platelets, as well as in myeloid cells, and weak activity was sometimes seen in lymphocytes and erythrocytes. On the other hand, Moloney *et al.*[4], and Löffler[5], who used cold 10 per cent formal–methanol fixation[6], found activity only in cells of the myeloid series. When 'Naphthol *AS-D* acetate' or 'Naphthol *AS-OL* acetate' were used as substrates, strongest activity was observed in most monocytes and weaker activity in all other cell types including platelets. Similarly stained

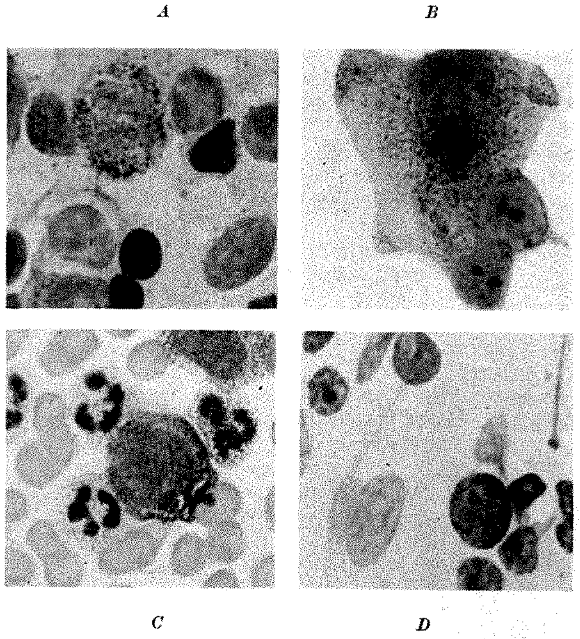

Fig. 1. *A*, imprint of rat spleen stained for chloroacetyl esterase using 'Naphthol *AS-D*-chloroacetate' as substrate, pH 7·1 (× *c.* 1,130); *B*, tissue culture smear, *HEp*-2 (human epidermoid), stained for acetyl esterase using 'Naphthol *AS-OL* acetate' as substrate, pH 7·1 (× *c.* 470); *C*, imprint of rat spleen stained for alkaline phosphatase activity using 'Naphthol *AS-BI* phosphate' as substrate, pH 9·5 (× *c.* 760); *D*, peripheral blood smear, chronic myelogenous leukæmia, stained for chloroacetyl esterase activity using 'Naphthol *AS-D*-chloroacetate' as substrate, pH 7·1 (× *c.* 760)

slides previously fixed in cold 10 per cent formal–methanol showed only very weak staining in some neutrophils and in some monocytes The use of 60 per cent citrate buffered acetone as a fixative for acetyl esterase and cold 10 per cent formal–methanol as a fixative for the enzyme-hydrolysing chloroacetates was helpful in distinguishing immature myeloid elements from immature monocytes, as was pointed out by Moloney[7].

The fixative solution is used and stored at room temperature and is prepared by adding 300 ml of absolute acetone, while stirring, to a mixture of 32 ml of 0 03 M sodium citrate (dihydrate) and 168 ml of 0 03 M citric acid (monohydrate)

Previously, 60 per cent aqueous acetone was suggested as a fixative for succinic dehydrogenase by Quaglino and Hayhoe[8] Optimal cell preservation is not obtained with the aqueous solution and in some cases less activity was observed as compared with that obtained on smears fixed with the acid-buffered acetone mixture

The availability of a fixative capable of simultaneously preserving enzyme activity and cell morphology should prove of value to those utilizing techniques for the cytochemical localization of enzymes in smears.

Preparation of Thick Sections for Cytochemistry and Electron Microscopy by a Non-freezing Technique

At present thick $(\sim 50\mu)$ frozen sections of fixed tissues are commonly utilized for cytochemistry and electron microscopy[1-3] despite the fact that freezing and thawing are known to cause disruption of fine structure and loss of enzymatic activity even in fixed tissues[3,4] These disadvantages have been tolerated since use of sections not exceeding 50μ is necessary to ensure even penetration of incubation media[1,2], and no alternative sectioning method has been available

We have recently developed a non-freezing technique for preparing such thick sections that results in greatly improved preservation of cellular structure while retaining higher levels of enzyme activity than the usual frozen section procedures Sections are cut with a McIlwain mechanical tissue chopper (manufactured by Gomshall-Surry), an instrument ordinarily used to prepare somewhat thicker slices of fresh tissue for metabolic investigations[5]

We have found the following technique satisfactory for cutting sections of about 50μ A piece of fixed tissue (about 1 2 × 1 0 × 5–10 mm) is placed in the centre of a pad composed of 6–7 pieces of 5 5 cm filter paper (Whatman No 1) held together with 'Cellophane' tape The tissue is covered with a few drops of liquid 7 per cent agar (or a low melting point paraffin) dripped on to its surface with a warmed dropper pipette (The agar solution is liquefied by heating in a water bath and subsequently stored at 42° C during use) The pad containing the tissue is placed in the refrigerator for several minutes until the agar hardens It is then secured to the circular metal table of the chopper with a few drops of paraffin placed between the bottom piece of filter paper and the metal table The chopper is set to cut at 0 052 mm and a double-edged razor blade (Schick stainless steel) is mounted in the holder The speed control is set at about 200 strokes per minute, and the chopper arm is positioned so that it barely contacts the left edge of the specimen. The instrument is switched on and allowed to remain so until the specimen has been completely traversed by the chopping action of the machine, which passes through the tissue from left to right The sections are then removed from the agar and placed in the desired solution, where they readily separate The entire operation takes less than 10 min

We have utilized the foregoing technique to prepare sections of a number of tissues (for example, pituitary, liver, intestine, kidney, pancreas, skin) fixed in 2–3 per cent glutaraldehyde (buffered at *p*H 7 2 with 0 1 M caccodylate buffer[3]) and stored for variable periods in buffer The sections have afterwards been treated by several histochemical procedures, 'post-fixed' in osmium and embedded in 'Araldite' When examined in the electron microscope these tissues have consistently showed a substantial improvement in general morphology, intensity of histochemical reaction and sharpness of localization of enzyme activity over those prepared by frozen section techniques Improved enzyme survival was demonstrated by the fact that shorter incubation times could be utilized for the non-frozen than for frozen sections to achieve the same intensity of reaction Even more notable is the fact that carefully prepared chopper sections appeared nearly free of the gross defects (tears, gaps, large membrane discontinuities, retraction between cells), which in our experience invariably characterize to some extent the frozen sections

PATHOLOGY

Electrical Charge Density of Spleen Cells sensitized against *L*-strain Fibroblasts

It has previously been shown that homologous and heterologous spleen cells, sensitized against *L*-strain fibroblasts, have a marked cytopathic effect on the fibroblasts *in vitro*[1,2] It was thought useful to examine the electrical surface charge density of these sensitized spleen cells in view of the possible changes which occur at the cell surface during the process of sensitization This communication presents such results obtained by cell electrophoresis

Mice or guinea pigs were sensitized as described by Taylor and Culling[1]· briefly, this involved two intraperitoneal and one intrasplenic injection of *L*-strain fibroblasts over a period of nine weeks Five days after the intrasplenic injection the spleen was removed and weighed Polyvinylpyrrolidone brush smears of the spleen were stained by the acridine orange and Wright's techniques for differential cell counts (lymphocytes, pyroninophilic proplasma and plasma cells and occasional granulocytes) The spleen was then macerated and shaken with glass beads in Medium 199 to obtain a homogeneous cell suspension; sterile conditions were maintained throughout. The spleen cells were then washed four times in Medium 199 and a small aliquot taken for cell electrophoresis. 1 ml of the spleen cell suspension also was added to each of several culture tubes containing a 24-h growth of *L*-strain fibroblasts, viability cell counts on the fibroblasts were performed 24, 48 and 72 h after the addition of the spleen cells to assess the extent of fibroblast damage caused by the sensitized cells. In each experiment identical procedures were performed using normal spleen cells from litter mates.

The cell electrophoresis technique has been described previously[3], the spleen cell suspension was washed in isotonic saline and suspended in phosphate-sucrose electrophoretic buffer (*p*H 7.0, ionic strength 0.083, relative viscosity 1.21), the specific conductivity measurements were made on the cell suspension at the end of an electrophoretic run. Electrophoretic mobilities were converted to surface charge densities using the simplified Gorin equation.

† Fibroblast culture viability counts at 72 h
‡ Pyroninophilic proplasma and plasma cells as percentage of spleen cell count

The results are summarized in Table 1, where it will be seen that (1) spleens of sensitized animals are approximately two or three times larger than control animals, (2) sensitization causes an increase of plasma and proplasma cells in the spleen, (3) the cytopathic effect of the sensitized spleen cells is reflected by the smaller number of viable fibroblasts after incubation for 72 h with sensitized cells, compared with those incubated with normal cells; (4) the sensitized spleen cell suspensions invariably showed a slower cell electrophoretic mobility than non-sensitized spleen cells ($P > 0.001$), the average loss of surface charge density approximates 10.6×10^3 electron charges/μ^2 cell surface. Evaluation of detailed cellular morphology is difficult in the electrostatic apparatus, thus limiting attempts to correlate cell mobilities with their morphological and functional characteristics. However, despite heterogeneity of the sensitized spleen cell populations, their electrophoretic mobilities were quite uniform.

The fall in surface charge density associated with the emergence of sensitized (plasma and pro-plasma) cells is somewhat surprising in view of the evidence to suggest that proliferating cell populations have a higher surface charge density than their resting counterparts[4]. The fall in surface charge density may be due to (1) an expansion of the cell surface, (2) re-alignment of surface ionic groups, or (3) the presence of γ-globulin on the cell surface; this possibility seems plausible in view of the fact that sensitized cells are involved in antibody synthesis, furthermore, γ-globulin has the slowest electrophoretic mobility of the plasma proteins.

In conclusion, homologous and heterologous spleen cells that have been sensitized against *L*-strain fibroblasts are cytopathic to the fibroblasts in culture. These sensitized spleen cells have a significantly lower surface charge density than normal spleen cells from control animals. This difference may be due to the presence of cytotoxic antibody γ-globulin on the surface of the sensitized cells.

Inhibition by Urethan (Ethyl Carbamate) of Virus Induction of Leukæmia in *C3H* Mice

URETHAN is now known to be a multipotent carcinogenic agent[1]. Its leukæmogenic action in adult mice is only slight[2], if at all[1,4]. However, it has been shown to act as an 'incomplete' carcinogen in adults in potentiating the leukæmogenic effects of total-body irradiation[3,4], and of œstrogens and polycyclic hydrocarbons[3]. More recently, urethan has been shown to exert a striking leukæmogenic effect when administered to some strains of mice shortly after birth[5-7].

In the work recorded here the effect was examined of urethan introduced during the neonatal period in the low-leukæmic *C3Hf/Lw* strain of mice and in its recently derived, genetically comparable, high-leukæmic sub-line C3Hf*/Lw, in which Moloney leukæmogenic virus (MLV) is transmitted through the mother's milk to successive generations[8,9].

Mice 24–72 h after birth received subcutaneously either a single injection of urethan dissolved in distilled water (4 per cent solution) at a dosage of 1 mg/g body-weight or the same dosage given for 4 consecutive weeks beginning in mice 24–72 h of age. Mortality in the latter group was considerable, but recovery of survivors was rapid.

Table 1 shows the results obtained in a 10-month period of observation. Low-leukæmic *C3H* mice did not develop lymphocytic neoplasms at either dosage-level of urethan. Multiple hepatomas were, however, found at necropsy in both sexes and at 10 months in both groups. Neoplasms of reticular tissues, principally lymphocytic leukæmia, occur spontaneously in the *C3Hf/Lw* strain at a frequency of approximately 10 per cent, but rarely before 12 months of age, and hepatomas occur with a moderate frequency among males, but usually beyond a year of age[10].

A striking inhibition of lymphocytic neoplasms, principally of thymic origin, was found in those high-leukæmic C3Hf*/Lw mice of both sexes given urethan at both dosage-levels. This inhibition is reflected in both frequency and latent period. Untreated controls in these groups 3*b* and 4*b* of Table 1 were either litter mates of the injected mice, housed in the same cages, or were prior or subsequent litters born to the same mothers. In those few C3Hf*/Lw urethan-treated mice which came to necropsy at 10 months of age there was found, as in the low-leukæmic sub-line, a high frequency of multiple hepatomas in both males and females. Lung adenomas were rare.

A group of *BALB/c* mice receiving 1 mg/g urethan at 24–72 h of age remained non-leukæmic and were killed at 10 months of age. No hepatomas were found, but 89 per cent had multiple lung adenomas (25/27 females and 20/24 males).

Although a strikingly enhanced susceptibility to urethan has been recorded in several stocks and inbred strains of mice given the compound parenterally[5-7], or orally[11] as

Table 1. EFFECT OF URETHAN, ADMINISTERED TO NEW-BORN MICE, ON THE FREQUENCY OF LEUKÆMIA AND OTHER NEOPLASMS

Group	Sub-line of mice	Effective No. mice	Dose of urethan	No. and % leukæmic	Age at death in days (range)	No. with hepatomas / No. necropsied	No. with lung adenomas / No. necropsied
(1)	*C3Hf/Lw* (low-leukæmic)	20	1 mg/g	0	—	15/20*	0/20
(2)	,, ,,	12	1 mg/g ×4	0	—	9/10	1/10
(3*a*)	*C3Hf*/Lw* (high-leukæmic)	24	1 mg/g × 4	8† (33%)	225 (150–300)	6/6	0/6
(3*b*)	,, ,,	79	None	66 (84%)	201 (120–270)	—	—
(4*a*)	*C3Hf*/Lw* (high-leukæmic)	18	1 mg/g ×4	1 (5·5%)	300	6/6	2/6
(4*b*)	,, ,,	25	None	13 (52%)	187 (140–234)	1/10	0/10

* Multiple hepatomas in urethan-treated mice. Of 24 mice with multiple hepatomas, 15/18 were in females and 9/12 in males; 4–25 separate tumours were found in individual mice and these varied in size from 4 to 10 mm (diam.).

† All the leukæmias encountered in this work were generalized lymphocytic (stem cell) and apparently thymic in origin. No sex differences were observed in frequency or latent period among leukæmics either in those groups showing inhibition by urethan or in the control groups.

‡ 2–6 lung nodules found in individual mice and these varied in size from 1 to 3 mm (diam.).

new-borns or early in life, it is clear from the results presented here that induction of leukæmia (or other neoplasms) is not a general phenomenon but is apparently quite dependent on the genotype of the animal. In another *C3H* sub-line, for example *C3H/Bi*, given urethan parenterally at birth, lymphocytic neoplasms were encountered in 40 per cent of the mice (females only) and a pronounced sex differential was observed in hepatoma induction[12]. Male *C3H* mice of 3 different, but related, substrains have been shown previously to have an increased frequency of hepatomas when given urethan parenterally as adults[13].

C3Hf/Lw mice, though susceptible to MLV and capable of replicating and transmitting virus through successive generations, are insensitive to urethan induction of lymphocytic leukæmia. The inhibitory influence of urethan observed in the high-leukæmic *C3Hf*/Lw* sub-line signifies that the potentiation or promoting effect of urethan[3,4] may indeed also be a limited phenomenon.

Electron Microscope Observations of Tumour Cell Cultures in the Presence of Lysozyme

IN earlier works, one of us[1] reported that lysozyme extracted from chicken egg albumen, added in suitable concentrations to human cell cultures, induced metachromatic granulations in the cell cytoplasm. Little information has so far been obtained on the nature and significance of these granulations, in spite of a number of investigations carried out to investigate their relationships with the host cell, their tinctorial properties and their reactivity to cytochemical tests.

The evidence obtained provided some help for a better outline of further work. Thus, it could be seen that lysozyme granules in cell smears, either dried in the air or fixed by heating, give a metachromatic violet reaction when stained with methylene blue or toluidine blue. Nucleic acid, lipid and polysaccharide reactions were negative. The extracellular origin of these granules was rejected. They were found to occur only in cells under metabolic and reproductive activity, and their presence would not seem to modify normal cell development.

A preliminary electron microscope investigation on lysozyme-treated cells showed the presence, in some cytoplasm vacuoles, of small structureless heaps which probably correspond to the granules observed by the light microscope[2].

Information obtained by a fuller investigation of such processes is reported here, special consideration being given to their relationship with endocytoplasmic structures. Hep 2 strain of epithelial origin, kindly supplied by Dr. A. Fjelde (State Serum Institute, Copenhagen), was used.

Cell colonies were grown on coagulum from chicken plasma and embryonal extract, using 199 or Gey's culture medium to which was added human and calf serum.

Lysozyme chloride was added to the cells being tested, in the proportion of 3 mg/ml. nutrient culture medium. 24–36 h later, after the appearance of lysozyme granules had been proved by the light microscope, colonies were removed, fixed with osmic acid and embedded in metacrylate, following the usual procedures. Sections 400 Å thick were made and examined by electron microscope.

Before describing the changes induced by lysozyme in Hep 2 cells, we should consider the appearance of cytoplasm membranes in untreated cells, since the aforementioned granulations seem to develop on these structures.

In cytoplasms of untreated cells, changes due to collections of multilayered membranes are regularly observed. These show a concentric appearance, are onion- or ring-shaped, or arranged like lamellar coils, grouped at the periphery of a large vacuole in which they are contained (Fig. 1).

Fig. 2 shows the same Hep 2 strain after treatment with lysozyme chloride under the aforementioned technical procedures: the homogeneous small heaps, oval or round-shaped, of different sizes, weakly opaque, contained in the vacuoles or membranous formations, may be identified with lysozyme granules. These granules are closely related to the multilamellar membranous structures from which they seem to originate following a homogenization process induced by lysozyme.

Among the proposed views on the nature and genesis of the granules under discussion, that of a direct action of lysozyme on some constituents of the endocytoplasmic reticulum deserves consideration. This hypothesis would suggest, rather than a simple linkage between proteins of different electric charge, an attack of the lysozyme on cell membranes through an enzymatic mechanism of homogenization of the fibrillar structure, resulting in the formation of granules.

If these experimental observations are confirmed, lysozyme will acquire a significant role in the examination

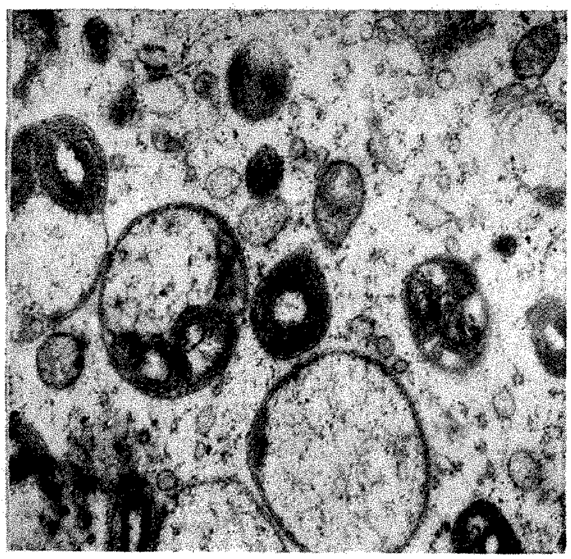

Fig. 1. × 35,500

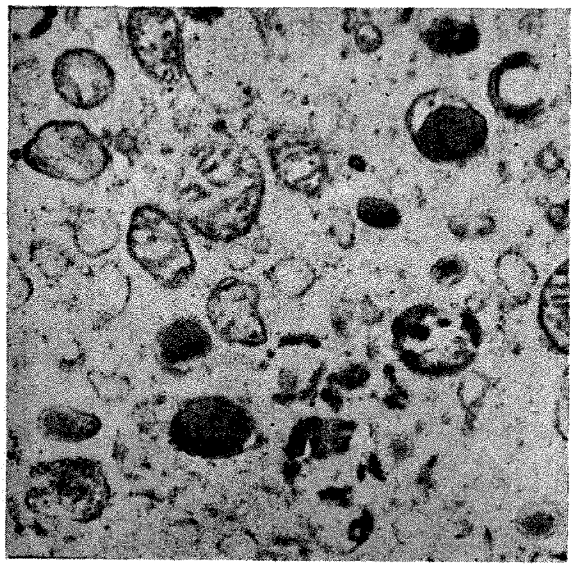

Fig. 2. × 20,500

of the biochemical nature of cytoplasm membranous formations and of interference with the reactive processes of such membranes during viral infections and other pathological conditions of cells.

Effects of *p*-Dimethylaminoazobenzene on the Fine Structure of Rat Liver Cells

INTEREST is at present being shown in the changes which carcinogenic agents induce in the fine structure of liver cells. When substances such as thioacetamide[1], dimethylnitrosamine[2] and ethionine[3] are administered to rats, a constant and early change is a hypertrophy of the smooth elements of the endoplasmic reticulum. In some cells there is also the formation of whorled structures composed of smooth paired membranes. So far as *p*-dimethylaminoazobenzene is concerned, the only investigations reported so far are those of Porter and Bruni[4], and Hübner[5]. These workers described a hypertrophy of the endoplasmic reticulum, but made no mention of whorl formation.

The animals used in the work recorded here were albino male rats of a local strain which had been fed maize containing 1 per cent *p*-dimethylaminoazobenzene. They were killed after 7 months of feeding, by which time several hepatocellular and cholangio-carcinomas had developed. Non-neoplastic portions of liver were fixed in Palade's fixative and embedded in methacrylate. Localization of the changes in relation to the portal tracts was facilitated by examination of thick sections stained by toluidine blue.

It was found that the endoplasmic reticulum had been transformed into a honeycombed mass of vesicles of varying sizes (Fig. 1). They did not contain any electron-dense material and were clearly delimited by smooth cytoplasmic membranes. At random points the membranes were more densely crowded together, and here varying stages of whorl formation were evident (Fig. 2). These structures consisted of circularly arranged paired membranes surrounding an inner zone which contained faintly electron-dense material or poorly outlined membranes. Up to ten pairs of membranes were counted in a single whorl, at the periphery of which the membranes merged with those lining the vesicles. Although most of the mitochondria were normal, some were irregularly shaped, while others were swollen, granular and possessed incon-

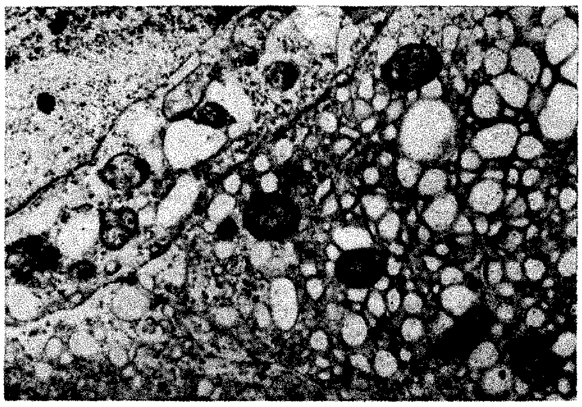

Fig. 1. The endoplasmic reticulum has been converted into a mass of vesicles lined by smooth membranes. Portions of three cells and a nucleus are shown

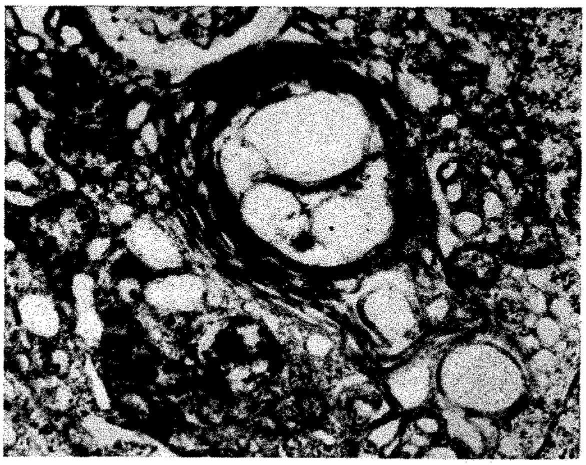

Fig. 2. An area of whorl formation. The paired membranes appear to be continuous with those lining the vesicles. A few irregularly shaped mitochondria are present

spicuous cristæ. Occasional nuclei had a very irregular and crenated outline, but no gross nucleolar abnormalities were noted. Some cells contained many dense bodies and lipid inclusions. Examination of the thick sections revealed that all the cells studied were periportal in situation.

The changes we have observed in the endoplasmic reticulum appear similar to those following the administration of thioacetamide, dimethylnitrosamine and ethionine, but as yet we do not know when they first appear and what proportion of cells exhibit them. It is of interest that four different hepato-carcinogens should produce similar alterations in the fine structure of cells. In attempting to evaluate the significance of the hypertrophy of the endoplasmic reticulum and whorl formation in relation to the mechanisms of carcinogenesis, their possible non-specificity should be borne in mind. In this connexion, laminated aggregates of membranes followed the administration of DDT to rats[6], while whorled structures appeared in mouse liver cells infected with the virus of Rift Valley fever[7]. In the latter case, however, the membranes were studded at regular intervals by dark transverse bands, thus differing from those induced by carcinogenic agents. Hypertrophy of the endoplasmic reticulum without whorl formation has also been described in starvation-refeeding experiments[8] and after feeding DL-β-3-thienylalanine[9].

Phenacetin-induced Papillary Damage in Experimental Animals

DURING the past ten years many reports have appeared describing the association of chronic interstitial nephritis and renal papillary necrosis with chronic ingestion of phenacetin-containing analgesic tablets[1–5].

Although there is overwhelming circumstantial evidence in favour of such an association, some authors still doubt whether there is a causal relationship between phenacetin ingestion and renal disease[6,7]. In an attempt to clarify the problem large doses of phenacetin have been fed to animals over prolonged periods of time; but these experiments have yielded equivocal results. Thus, Studer *et al.*[8] found little change in the kidneys of rats fed phenacetin and this was later confirmed in rabbits[9] and guinea pigs[10]. Thölen *et al.*[11] described interstitial nephritis in mice, but these animals were prone to spontaneous urinary infection with *Closiella muris*. Similarly, rabbits fed on phenacetin and afterwards injected intravenously with *Escherichia coli* developed interstitial nephritis[12], but this finding has not been confirmed[13]. Angervall *et al.*[14] have shown that phenacetin and *N*-acetyl-*p*-aminophenol fed to rats over a long period of time increased their susceptibility to the development of hæmatogenous interstitial nephritis. Recently, Eisalo and Talanti[15] have described changes of chronic interstitial nephritis in rats given 100 mg of phenacetin daily for one month. The lesions were associated with disappearance of enzyme activity in the renal tubular cells. However, as yet there is no published experimental work describing the occurrence of papillary necrosis in animals fed on phenacetin preparations.

We have administered tablets containing phenacetin alone and others consisting of aspirin, phenacetin and caffeine (A.P.C.) to groups of Wistar rats over fifteen

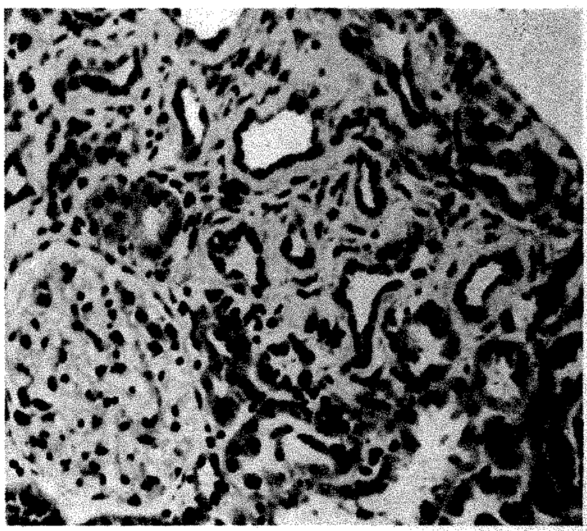

Fig. 1. Section through the renal cortex of a rat fed A.P.C. tablets for a period of seven months. There is interstitial fibrosis, tubular basement membrane thickening and tubular atrophy (hæmatoxylin and eosin, × 600)

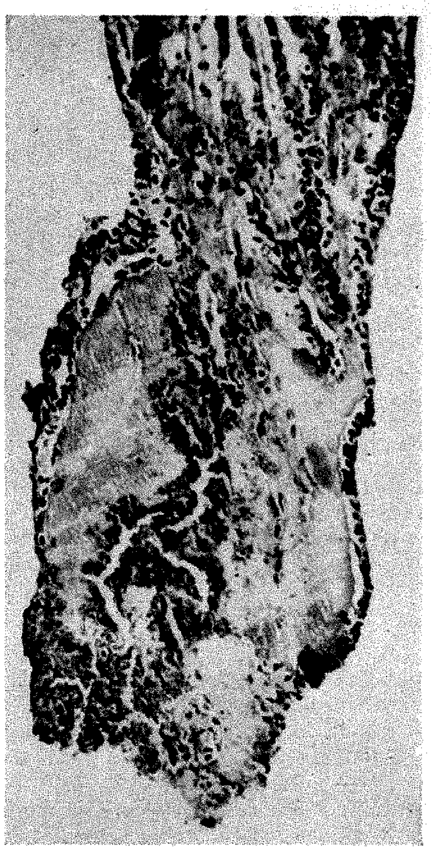

Fig. 2. Section through the renal papilla of a rat fed phenacetin tablets for a period of seven months. The papilla is distended with extensive hæmorrhage (hæmatoxylin and eosin, × 400)

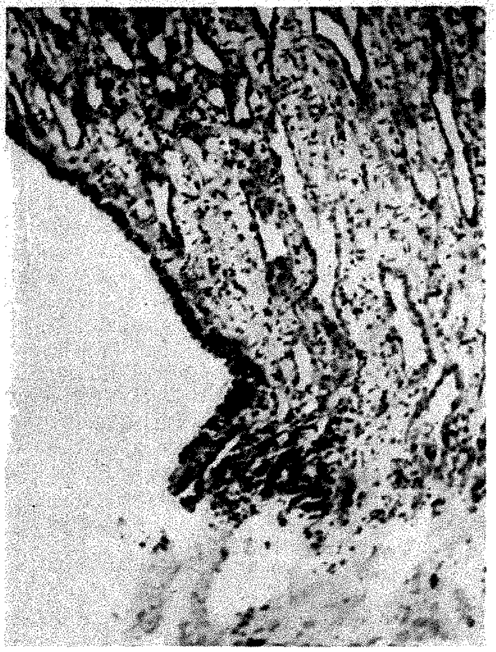

Fig. 3. Section through the renal papilla of a rat fed A.P.C. tablets for a period of eight months showing total papillary necrosis with minimal cellular infiltrate (hæmatoxylin and eosin, × 300)

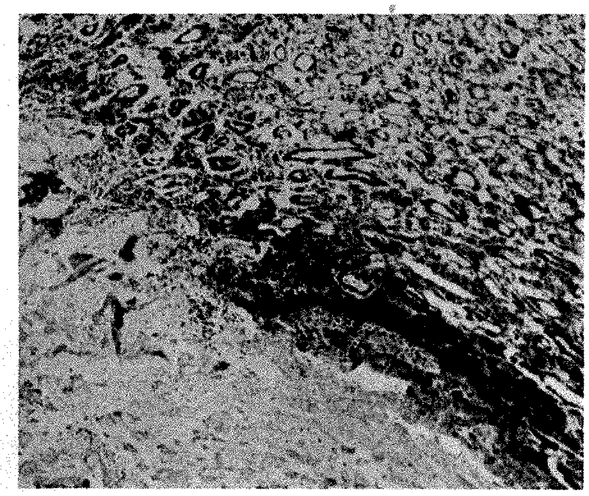

Fig. 4. Section through the renal papilla of a rat fed A.P.C. tablets for a period of 14 months. There is total papillary necrosis with a marked granular and non-granular cell infiltrate (hæmatoxylin and eosin, × 120)

months. The tablets were crushed in a mortar and mixed with fine rolled oats. The total intake of phenacetin by each rat varied from 1,000 to 14,000 mg.

Three types of lesions were observed in the experimental animals:

(*a*) An interstitial fibrosis with thickening of the tubular basement membrane and tubular atrophy occurred in both the phenacetin and A.P.C. groups (Fig. 1). Although this change did occur in control animals, it was quantitatively and qualitatively less marked than in the other two groups.

(*b*) Severe hæmorrhage into the renal papilla occurred in 20 per cent of the rats in the A.P.C. and phenacetin groups (Fig. 2). A small area of hæmorrhage occurred in one control animal.

(*c*) Papillary necrosis was observed in two rats. The first had been fed A.P.C. tablets for 8 months and the renal papilla was totally necrosed. There was minimal cellular infiltrate and bacteria were not present (Fig. 3). The second rat, which had been fed A.P.C. tablets for 14 months, showed papillary necrosis in which there was both a granular and non-granular cell infiltration (Fig. 4). There were scattered foci of Gram-negative bacilli present. No such changes were observed in the control group.

The production of papillary damage in rats fed on phenacetin provides convincing support for causal relationship between prolonged phenacetin abuse and renal damage.

IMMUNOLOGY

Transfer to Neonatal Chickens of the Primary Antibody Response initiated *in vitro*

THERE are numerous reports on the formation of antibody by neonatal animals which had been injected with homologous spleen and lymph node cells mixed *in vitro* with bacterial antigens[1–3]. Transfer to neonatal recipients of a primary response to serum protein antigens under similar conditions has often met with failure or with poor antibody responses[3]. The latter has been attributed either to the unsuitability of the neonatal environment for the cells[4,5] or to the possibility that soluble proteins have a longer induction period, and as a consequence the homograft reaction results in damage of the cells before antibody is demonstrated[6]. To obviate this, Holub and Říha utilized diffusion chambers which protected the transferred adult cells from the rejection mechanism. The present report summarizes further attempts to initiate an antibody response by *in vitro* mixing of chicken spleen cells with either bovine serum albumin (BSA) or with BSA–anti-BSA complexes, and subsequent transfer to neonatal chickens.

Tissue culture Mixture 199 (pH 7·0) containing heparin and penicillin was used throughout this work. The procedure for preparation of spleen homogenates was similar to the method described by Papermaster[8]. Spleens were obtained from adult Austra white hens and homogenized in a Potter tissue grinder. The cells were suspended in the various test solutions and diluted to give concentrations of $1 \times 10^8 - 1 \times 10^9$ cells/ml. The test and control cells were incubated at 37° C for 30 min, and in some experiments the cells were washed 3 times with Mixture 199 after incubation Neonatal cockerels or pullets (12–36 h old) were given a single intraperitoneal injection of 1 0 ml of the cell suspensions, and were bled 6 days later. The sera were heated at 56° C for 30 min, adsorbed with sheep red blood cells, and assayed for antibody by the tanned cell method[9] Sera from the donors had no anti-BSA titres, and the antibody responses of recipient chickens were found to be specific as determined by hæmagglutination inhibition tests

In preliminary experiments, cells which had been incubated with concentrations of BSA higher or lower than 1 0 mg gave poor responses, and no antibody responses were demonstrated in chickens which were injected with either 1 0 or 0 1 mg of BSA without cells In subsequent experiments 1 0 mg of BSA was used as the sensitizing dose, and the results are summarized in Table 1 Various controls were included and are summarized as follows Only 2 of 51 chickens produced hæmagglutinin titres of 1 10 following injection of 1 0 mg BSA (no cells) Cells which had been incubated with BSA followed by disruption by 5 cycles of freezing and thawing failed to form antibody Responses obtained with washed and unwashed sensitized cells were similar Incubation of cells with BSA and chicken anti-BSA antibody complexes (Exp 2 and 4) did not produce titres higher than cells incubated only with antigen Small amounts of antibody appeared in recipients injected with cells which had been incubated with high-titre chicken antibody and washed In Exp 1, high titres were produced by cells which had been incubated with primary chicken anti-BSA antibody containing a high concentration of high molecular weight (19*S*) hæmagglutinin[10], and then followed by incubation with BSA and washing We were unable to repeat the production of these high titres in subsequent experiments, and the results suggest that either a secondary response was elicited, although the donor sera were negative for anti-BSA, or that the antibody was passively transferred

The antibody responses to cells exposed only to antigen were erratic, and this might be related to the sex of the recipients In 3 experiments with cockerels no measurable titres were obtained (1 10 or above), however, there were always some chickens which produced antibody in experiments in which pullets were used Apparently antibody synthesis was initiated *in vitro* rather than as a result of active sensitization of the recipients to antigen transferred with cells Fifty-five chickens (pullets and cockerels) were injected with antigen-exposed cells (washed and unwashed), and 16 chickens or 19 per cent produced titres of 1 10 or greater, whereas only 2 or 4 per cent of 51 chickens injected with BSA produced titres of 1 10 Furthermore, 64 per cent (9/14) of the pullets produced antibody in response to cells plus antigen, and no titres were detected in 13 pullets injected with antigen alone Whether a difference in the degree of maturity between neonatal sexes exists, and, consequently, pullets may represent a more effective host for potentially antibody-producing cells, remains to be clarified

*Neonatal chickens bled 6 days following transfer of $1 \times 10^8 - 1 \times 10^9$ cells

† Reciprocal of hæmagglutinin titre, numbers in parentheses refer to number of chickens

Evidence for the high molecular weight nature of the antibody synthesized in neonatal chickens was obtained by sucrose density gradient ultracentrifugation[10] Hæmagglutinating activity was associated with the 19*S* globulin fractions, thus yielding evidence that a primary response was induced[10,11]

Preparation of *Vipera palestinae* Antineurotoxin using Carboxymethyl-cellulose-bound Neurotoxin as Antigen

THE separation and characterization of two distinct toxic components of *Vipera palestinae* venom, hæmorrhagin and neurotoxin, by the use of electrophoretic and chromatographic methods, have been previously reported[1,2] Numerous attempts made in this laboratory over a number of years to prepare potent viper antineurotoxin by using neurotoxic fractions for immunization have been unsuccessful[3] Superimposed immunization with neurotoxic fraction of rabbits previously immunized with whole venom did raise the antineurotoxin titre but not to a sufficient level[4]

It was observed, during investigations of column chromatography fractionation of *Vipera palestinae* venom, that, while the neurotoxin elutes from a 'DEAE-cellulose' column, it is firmly bound to a carboxymethyl-cellulose column[2] Binding of sea snake toxin to the latter resin was recently reported by Carey and Wright[5] The present report deals with the effect of carboxymethyl cellulose (CMC) on the toxicity and immunogenic activity of the neurotoxic fraction of *Vipera palestinae* venom

The neurotoxin-binding capacity of CMC was tested using CMC in a non-soluble form, prepared according to the method of Peterson and Sober[6] from Whatman ashless standard cellulose powder, mesh 325 (H Reeve Angel and Co , Inc , New York) The CMC preparation was suspended in phosphate buffer 0 005 M, *p*H 6 8 The neurotoxic fraction was an eluate from a 'DEAE-cellulose' chromatography column[2] The amount of neurotoxin which combines with CMC was measured by adding increasing lethal doses of the neurotoxic fraction to constant amounts of CMC Following moderate centrifugation, the supernatant was titrated for toxicity by intraperitoneal inoculation of mice weighing 20 g, and the LD_{50} calculated according to the method of Reed and Muench[7] It was found that 1 g of insoluble CMC binds up to 390 LD_{50} of the neurotoxic fraction

Antisera against the CMC-bound neurotoxin were prepared in rabbits As controls, antisera prepared in rabbits by the use of neurotoxic fraction alone were utilized Since the insoluble form of CMC could not be used for immunization of rabbits, the neurotoxic fraction was bound to CMC in soluble form Toxicity tests of this CMC-neurotoxin complex proved that 300 LD_{50} of added neurotoxin was detoxified by 1 g of soluble CMC

Two immunization experiments were carried out using 3 rabbits each The antigen was mixed in equal parts with Freund's complete adjuvant prior to inoculation Primary immunization was carried out by two intradermal injections into two foot-pads each, within one week, followed after an interval of ten days by a single subcutaneous injection The amounts of CMC-neurotoxin complex used for these two primary inoculations were equivalent to 2 and 17 mouse LD_{50} respectively The rabbits were bled one week following the subcutaneous inoculation Two months later a subcutaneous 'booster' injection was given, equivalent to 37 5 LD_{50} of CMC-bound neurotoxin One week after the booster the animals were re-bled from the heart Pre-, post-primary-, and post-booster immunization sera were tested for their capacity to neutralize the neurotoxic fraction Varying amounts of the respective sera, pooled from 3 rabbits, were mixed with different amounts of LD_{50} The mixtures were inoculated intraperitoneally in mice and the protective effect compared with that of antisera prepared against neurotoxin alone It will be seen in Table 1 that the sera of rabbits immunized by CMC-bound neurotoxin contained an appreciable amount of specific antibody capable of protecting mice against the neurotoxic fraction The titre of antineurotoxin increased significantly following the booster inoculation The antiserum was found to neutralize specifically the neurotoxic component of viper venom and not its hæmorrhagin It did not neutralize whole viper venom, the test animals dying with hæmorrhage

The results obtained in the present work show that large amounts of neurotoxin can be detoxified by binding it to a suitable resin The method used made it possible to strengthen the immunogenic potency of viper neurotoxin to such a degree that minute amounts of resin-bound neurotoxin elicited a high antibody response In view of the low molecular weight shown to be characteristic for several venom neurotoxins[8–10], the increase in immunogenic activity attained by resin binding may be a reflexion of the increase in molecular weight of the antigen[9]

Table 1 NEUTRALIZING POWER OF RABBIT SERA IMMUNIZED WITH CMC-BOUND NEUROTOXIN

Antigen used for immunization	Sera	No of LD_{50} of neurotoxic fraction neutralized/ml serum
CMC-bound neurotoxin	Pre-immunization	0
	Post-primary	9
	Post-booster	30
Neurotoxic fraction alone	Pre-immunization	0
	Following numerous primary and booster inoculations	6

Formation of Antibody in Tissue Culture : Effect of Certain Mucopolysaccharides and Hexosamine

RECENT investigations have given insight on the mechanism of antibody synthesis *in vitro*[1–3] Fishman[4,5] has further developed *in vitro* systems in which a primary induction of antibody was achieved The reports of Alfred and Pumper[6] and of Ozzello[7] have described the use of certain mucopolysaccharides and other non-protein substances for growth of primary isolations and established tissue culture cell lines As a continuation of these investigations, the present communication aimed at testing the ability of two mucopolysaccharides and *N*-acetyl-*d*-glucosamine to promote the 'growth' and antibody formation by tissue cultures of chicken spleen fragments It is obvious that an *in vitro* system that would permit a clearly defined examination of the antibody induction process and the sequence of biochemical events which occur during the differentiation of cells into antibody-forming clones is a major problem

Adult chickens (2–3 months old) were given a single intravenous injection of 1 0 ml (5×10^8 organisms of *Salmonella paratyphi B* vaccine) After 24–28 h, the spleen was removed, cut into fragments (3 mm³, 15–20 mg each), and placed on stainless steel wire mesh strips (4 cm long, 1 5 cm wide) Three fragments were placed on each strip, each overlaid with a drop of 1 per cent agar[8], and allowed to stand at room temperature for 15–20 min The agar-embedded fragments were then cultured in 17-mm roller tubes in 2 0 ml of each of the following media (*a*) synthetic medium (*M*-199) alone, (*b*) *M*-199 + 50 per cent horse serum , (*c*) *M*-199 supplemented with either chondroitin-sulphate, hyaluronic acid, or *d*-glucosamine at varying concentrations The cultures were kept for 9 days during which period the growth fluids were collected, replaced with fresh medium, and the level of antibody was measured The antibody assay procedure was a measure of the agglutinating capacity of the growth fluid by 0 02 ml (1×10^7 organisms) of the original vaccine according to Corvazier and Cochrane[9]

An average of the results of 10–12 experiments is shown in Table 1 Medium-199 (minus purines, pyrimidines, and nucleotides) was nutritionally insufficient for antibody formation by cultured spleen tissue from sensitized chickens However, when this basal medium was supplemented by serum (group 2), chondroitin-sulphate (group

7	,,	0 5 ,,	0	4	4	16	4
8	,,	0 25 ,	0	0	4	16	0
9*	Serum	50 per cent v/v	32	32	32	32	32

* Control Spleen fragments from non-injected chickens

3) hyaluronic acid (group 4), or *d*-glucosamine (group 5), each of these mixtures permitted the biosynthetic processes of antibody formation It was found that there was a limiting concentration of each of these supplements below which antibody formation decreased or disappeared The chemically defined mixture of *M*-199 + *d*-glucosamine was of interest since it appeared to have a stimulatory activity higher than that of chondroitin-sulphate or hyaluronic acid and possibly analogous to the activity of the serum component

It was further demonstrated that there was a lag period in antibody formation in a nutritionally optimal medium and antibody synthesis reached a peak in 6 days and continued in some cases for longer periods Fig 1 shows a comparison of the antibody-forming capacity of tissue cultivated in various media as a function of incubation time Control cultures, containing spleen tissue from non-injected chickens, grown in each of the media, showed the absence of antibody formation These controls also demonstrated that the low agglutinating antibody titre to *Salmonella paratyphi B* normally found in the serum of chickens (1 8) before injection of antigen was not detectable in the cultured spleen fragments or saline soluble extracts of homogenates of the spleen tissue prior to cultivation

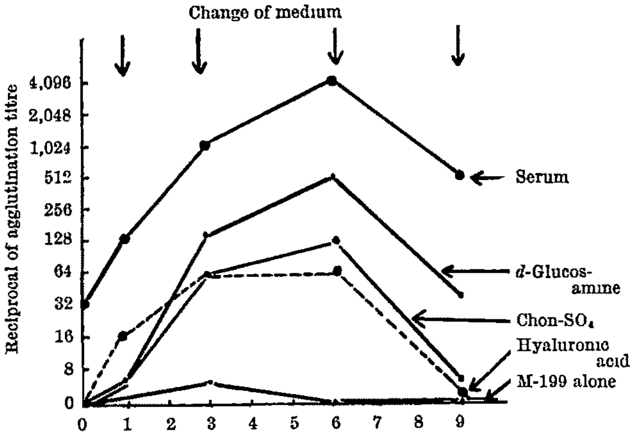

Fig 1 Response of cultured spleen fragments to serum (50 per cent), mucopolysaccharides (1 mg/ml), and D-glucosamine (1 mg/ml), each dissolved in *M*-199

It was desirable to know if the antibody material which was produced in the synthetic mixture of *M*-199 + glucosamine could be separated from low molecular components of the growth medium and recovered in a reactive form (agglutinating ability) This was accomplished by applying a sample of freshly collected culture fluid to a 'Sephadex *G*-50' column which had been equilibrated with 0 005 M sodium phosphate buffer at *p*H 6 8, and washing the column with the same buffer At least 75 per cent of the agglutinating activity was eluted as a sharp peak in the initial column volume This manipulation afforded a simple way for obtaining a concentrated antibody-containing solution directly from the culture tube

These preliminary results indicate that the requirements for antibody formation *in vitro* need not be a complex protein-containing medium but that simplified solutions can establish the proper physiological conditions for this process The use of chemically defined glucosamine medium gives rise to a relatively clean environment in which one might study the nature of antibody precursors and of the finally synthesized antibody protein The fact that chondroitin-sulphate and hyaluronic acid promote antibody-forming activity in this system suggests that the hexosamine residue of these materials might be the active site However, the viscosity of the culture medium as affected by these mucopolysaccharides cannot be disregarded as a possible essential physiological condition It should be noted that the agar-overlay which was used to hold the spleen fragment on the wire mesh may have served another purpose in aiding in the maintenance of a certain degree of organ tissue organization Such organization may be necessary for the successful continuation of antibody formation which was induced *in vivo* Present experiments are directed toward the elucidation of the relationship between the changes in cell types of these spleen fragments at different time intervals of culture and the possible role of the nuclear RNA fraction of the cell types associated with the sequence of antibody synthesis

ANATOMY

Influence of Trypan Blue on Resorption of Rat Embryos

TERATOGENIC agents have been found to cause an increase in fœtal mortality as well as developmental malformations In a series of 206 embryos between 10½ and 14½ days of gestation from Wistar rats injected with 1 ml of a 1 per cent solution of trypan blue at 8½ days of pregnancy, 45 embryos, or 21 8 per cent, were found to be undergoing resorption These resorption products were examined and eight of them were serially sectioned at 5μ for histological investigation A number of sites of complete resorption were observed, but they were not counted, so that the total number of resorptions was considerably in excess of the 45 products examined Even so, this proportion of resorptions (21 8 per cent) is considerably greater than the 6 0 per cent of resorptions recorded by Beck *et al* [1] for a control group of Wistar rats, although much lower than the total resorption rate (56 2 per cent) recorded for rats injected with 1 per cent trypan blue in the same experiment

On gross examination, the resorption products were seen to be considerably shrunken while retaining a recognizable shape in the early stages Later resorption products gradually lost their embryonic shape and merged into the surrounding extra-embryonic tissues These embryos were more brittle than usual and the tissues flaked easily In advanced cases the amniotic secretion had formed a white gel, although at earlier stages there was amniotic fluid present and a white deposit on the surface of the embryos particularly in the depressions between the limb buds and the body wall The resorption products and their chorionic vesicles were invariably smaller than other embryos of the same litter Litter mates which were not resorbing showed a variation in size, some being retarded in general development with no other apparent deviation from the normal, while larger embryos displayed an abnormal heart structure

Microscopically the resorption products showed little evidence of the normal architecture of the embryo and displayed an irregular, cellular mass comprising macrophages, nucleated red blood cells and nuclear debris Many of the red cell nuclei had lost their surrounding cytoplasm and most of the nuclei were pycnotic. There were also areas of structureless coagulum

It has been suggested recently[2] that fœtal death is a secondary effect of the malformations produced by trypan blue The findings in the investigation reported here do not support this view Invariably the embryos which showed even the slightest degree of resorption were smaller than their litter mates but in the absence of resorption the smallest embryos did not display the greatest degree of malformation and usually showed no evidence of abnormal development apart from the retardation in growth

The extent to which the mammalian embryo relies for survival in the uterus on the development of its own tissues is very small indeed The main requirement is for adequate umbilical vessels and conducting vessels within the embryo, and these are not generally described as being affected by teratogenic agents, while abnormalities of the heart and great vessels are commonly found[3-5]. Indeed development of the embryo may continue following decapitation[6,7]

The resorption of rat embryos does not necessarily require the presence of a teratogenic agent such as trypan blue It is a non-specific phenomenon It has been the experience of the staff of the animal department of the Otago Medical School that complete resorption of whole litters may occur following rough or inordinate handling of the pregnant dam or without any obvious cause It is also known to occur in crowded conditions Such resorption may occur quite late in the pregnancy at a stage where differentiation (as opposed to growth) could be expected to be virtually completed

Trypan blue increases the resorption rate in pregnant rats by a mechanism which appears to affect all the embryonic tissues and the amniotic fluid, but this effect does not seem to be dependent on, or even specifically related to, developmental malformations other than that of growth retardation

The malformations in this series of rats will be reported at a later date

RADIOBIOLOGY

Production of Hydrogen Atoms in Teeth by X-irradiation

THE purpose of this communication is to report several electron magnetic resonance observations in human teeth *in vitro* The sample was a small section of the upper left incisor tooth of a 7-year-old female child The sample volume was 1–2 mm^3 Electron magnetic resonance spectra were obtained at the K-band (24 Kmc) with a high sensitivity electron magnetic resonance spectrometer using 100-kc/s field modulation and a cylindrical cavity operating in the TE_{011} mode The sensitivity of this spectrometer is approximately 10^{12} $(\delta H)^2$ spins, where δH is the resonance line-width in gauss

An initial search in the unirradiated material at room temperature disclosed no paramagnetic resonances in the region 3,300–10,200 gauss Since the $g=2$ value of magnetic field for the operating frequency was 8,500 gauss, this corresponds to a scan of g value from 5 2 to 1 7. respectively This means that there is no single paramagnetic species in the specimen which exceed the concentration 10^{12} $(\delta H)^2$ and the g value of which lies in this region

X-irradiation was afterwards performed in air at room temperature for 10 min with a tungsten target tube operating at 50 kV and 50 m amp and with the sample placed 4 cm from the target Immediately following irradiation the intense electron magnetic resonance spectrum shown in Fig 1*a* was observed at room temperature Fig 1*b* is the spectrum in the same sample 2 5 days following irradiation During this interval the specimen was maintained in air at room temperature Fig 1*c* is the integral of the central portion of Fig 1*b* and represents the absorption curve The spectra exhibit three salient features

(1) A broad line centred at $g=2$ 003 and approximately 20 gauss wide between the inflexion points A comparison of Figs 1*a* and *b* shows that this line has decreased by about a factor of 6 during the intervening time

(2) A 'Pake' shape[1] line the absorption curve maximum of which lies at $g=2$ 0004 This line is easily recognized in Fig 1*c* and has a full width of 20 gauss The signal intensity is essentially undiminished during the 2 5-days interval

(3) A weak doublet centred at $g=2$ 0029 ± 0 0003, corrected for second-order effects, and a splitting of 498 ± 2 gauss The width of each component is 5 gauss and the signal diminished by about a factor of 2 over the 2 5-days interval The spectrum was observed at 4 2° K with no change in shape The splitting of the doublet increased slightly to 502 ± 2 gauss However, the electron relaxation time at 4 2° K is longer than 0 1 sec

If the spin Hamiltonian of a paramagnetic species contains terms involving tensor quantities, for example, hyperfine and quadrupole tensors, the species will exhibit broad electron magnetic resonance lines of complex shapes[2] in a polycrystalline or amorphous material The lines near $g=2$ are of this type Identification of spectra 1 and 2 is therefore highly problematical Spectrum 2 probably arises from a defect having an anisotropic g tensor and containing only nuclei with zero spin Considering the chemical composition of teeth, this unpaired electron may be associated only with the calcium and/or oxygen nuclei Similarly, identification of spectrum 1 is not attempted at this time

Several conclusive arguments can be made for the identification of the doublet in spectrum 3 as hydrogen atoms A doublet electron magnetic resonance spectrum indicates that the unpaired electron in this defect interacts with only one nucleus with nuclear spin equal to ½ Wide-line nuclear magnetic resonance spectra on this sample show that large concentrations of both hydrogen-1 and phosphorus-31 are present No fluorine-19 line was observed indicating only a trace amount is possible These are the only spin ½ nuclei which are likely to be present in more than trace concentrations The observed splitting of 500 ± 2 gauss and the observed g-value of 2 0029 ± 0 0003 are in excellent agreement with the free atom values[3] of 508 gauss and 2 0023 Deviations of this

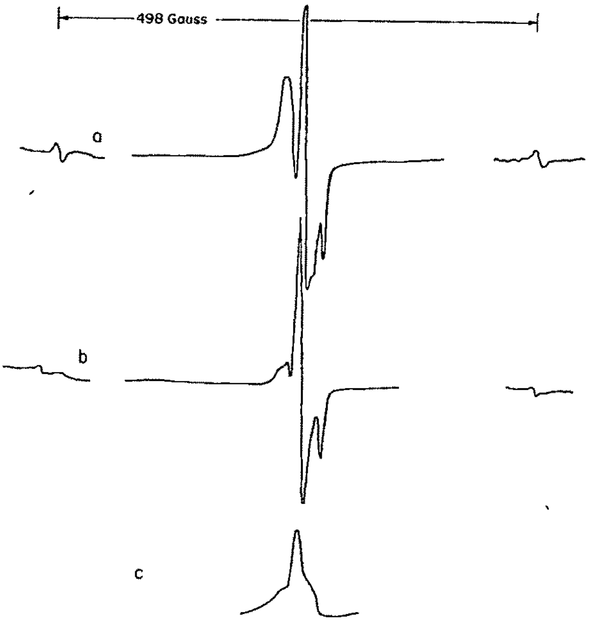

Fig 1 Electron magnetic resonance spectrum in X-irradiated tooth at room temperature *a*, First-derivative of the absorption immediately after irradiation, *b*, first-derivative of the absorption 2 5 days after irradiation, *c*, absorption curve corresponding to the central portion of *b* obtained by electronic integration Spectrometer gain was reduced by a factor of 10 in the central portions of *a* and *b*

magnitude and even greater have often been measured for trapped hydrogen atoms in a solid matrix[4]

The small width and symmetric shape for the doublet lines indicate that both the *g*-value and electron-nuclear hyperfine interaction are isotropic This fact also agrees with previous observations of hydrogen atoms in solids Conceivable molecular defects containing one hydrogen atom would have considerable anisotropy in both *g*-value and hyperfine coupling and would also show a much smaller doublet separation

Any phosphorus-containing defect in which the phosphorus nucleus is located at a point of less than tetrahedral symmetry would likewise possess *g* and hyperfine anisotropy[5] Phosphorus located at a defect of tetrahedral symmetry, as in phosphorus-doped silicon, would have isotropic hyperfine coupling of only 20–30 gauss[6] Atomic phosphorus likewise has a hyperfine splitting of 20 gauss[7]

Production of hydrogen atoms by radiation damage at low temperatures in several materials is well established The unusual aspect of this work is that hydrogen atoms have been produced and are relatively stable at room temperature in teeth The number of hydrogen atoms produced in the 1 mm^3 sample with 10-min irradiation is about 10^{15} atoms For the stronger unidentified species about 10^{18} defects are produced

We thank Dr J. J Lambe of this Laboratory for his aid in this work

A Fast-neutron Source for Radiotherapy

IT would be a pity if recent correspondence[1,2] were to give the impression that 14-MeV neutrons are known to be valueless for radiotherapy on account of their low linear energy transfer To my knowledge no measurements of the oxygen enhancement ratio of mammalian cells irradiated by 14-MeV neutrons have yet been published. An estimate of the value of this irradiation in treating tumours containing anoxic foci is therefore a matter of speculation.

In considering the effective linear energy transfer of 14-MeV neutrons, account must be taken of all the ways in which energy can be deposited in tissue At low energies nearly all the energy is deposited by recoil protons (94 per cent at 0 3 MeV[3]) As the neutron energy rises the proportion of energy deposited by recoil protons becomes less, owing to the falling cross-section for this process, and is only 70 per cent at 14 MeV[4] Randolph[4] made calculations at this energy allowing for the other interactions which can occur, and found a significant contribution from α-particles (mainly from the reaction $^{16}O(n,\alpha)^{13}C$) These α-particles presumably have a high relative biological effectiveness and so are biologically more effective than recoil protons An estimate of the radiobiological effect based on the linear energy transfer of recoil protons only is therefore likely to be a poor approximation

It is not at present possible to make a reliable estimate of the biological effects of these α-particles However, there is a general picture that, as the linear energy transfer rises, the relative biological effectiveness of mammalian cells rises to a maximum around 50 keV/μ and then falls again[5], while oxygen enhancement ratios fall steadily[6] The important parameter for therapy is the 'gain factor' defined by Alper[7] A gain factor of about 1 7 has been found for cyclotron-produced neutrons having a mean energy of 6 MeV[8] The gain factor for 14-MeV neutrons can only be estimated roughly, as the necessary radiobiological evidence is lacking It is likely to be less than 1 7, and a calculation assuming plausible values for the radiobiological properties of the components of 14-MeV neutron radiation (recoil protons and nuclei and α-particles) suggests it may be in the region of 1 5, which would still be of therapeutic value

Fowler[2] points out that the optimum neutron energy is likely to be a compromise between low energies giving high linear energy transfer but poor penetration, and high energies giving lower linear energy transfer but better penetration This implies that the optimum depends on the depth of the tumour treated It is quite possible that 14 MeV may turn out to be a suitable neutron energy for treating deep-seated lesions On the other hand, the difficulties of collimating the beam may be greater than seem to be imagined by Lomer and Greene[9]

While the value of a source of 14-MeV neutrons for therapy remains in doubt, the construction of a more powerful source than is at present available should be welcomed as an aid to radiobiological research

BIOLOGY

Effect of Lymphocyte Depletion by Thoracic Duct Fistula and Administration of Antilymphocytic Serum on the Survival of Skin Homografts in Rats

SINCE lymphocytes appear to play a crucial part in the homograft reaction it seemed of interest to examine the behaviour of homografts in recipients subjected to chronic lymphocyte depletion by (*a*) drainage of lymph through a thoracic duct fistula, (*b*) repeated administration of a hetero-specific antilymphocytic serum, (*c*) a combination of these procedures

The use of a thoracic duct fistula is based on the observation of Gowans, McGregor, Cowen and Ford[1] that rats challenged with tetanus toxoid or sheep erythrocytes after such a fistula has been maintained for 5 days fail to produce antibodies

The effect of a hetero-specific (rabbit-anti-rat) antilymphocytic serum on the behaviour of homografts of skin and endocrine tissues was investigated some years ago by Woodruff, Woodruff and Forman (cited by Woodruff[2]), but it was not found possible to maintain a lymphocytopenia for more than about 10 days, and no significant effect on homograft survival was observed, the serum used in the experiments recorded here has, however, proved to be much more effective

Albino rats of an inbred strain were used as skin graft donors, and hooded rats of a second inbred strain as recipients Fitted split skin grafts (2 cm × 2 cm) were used as described by Woodruff and Simpson[3] Thoracic duct cannulation was performed as described by Bollman, Cain and Grindlay[4] and Gowans[5] In rats undergoing lymph depletion the fistula was maintained for 5 days, during which time the total output was 1–2 × 10^9 lymphocytes

Antilymphocytic serum was prepared initially by giving random bred rabbits three intraperitoneal injections of 2 × 10^8 hooded rat thoracic duct lymphocytes at weekly intervals and bleeding 10 days after the last injection Immunized rabbits received a 'booster' intraperitoneal injection of 100–200 × 10^6 rat lymphocytes 10 days before subsequent bleeding The serum was used without prior absorption against rat erythrocytes It was assayed by measuring its capacity to produce a lymphocytopenia in normal hooded rats, and was accepted as satisfactory only if 2 ml injected intraperitoneally to a 200-g rat resulted in a fall in the absolute lymphocyte count of the peripheral blood to less than 2,000/mm^3 in 4 h

The treatment used and the period of homograft survival (assessed macroscopically) in the various experimental groups are set out in Table 1

It will be seen that lymph drainage and administration of antilymphocytic serum both resulted in prolonged homograft survival, the maximum effect was obtained when treatment was begun before grafting and continued thereafter

These results will be reported more fully elsewhere with an appraisal of their biological significance and their possible application in the surgery of replacement

Control of Egg Size in Chickens through Dietary Amino-acid Balance

THERE are conflicting reports regarding the influence of the level of protein and of specific amino-acids in the diet of the hen on egg size Results from an experiment in this laboratory suggested that the balance, rather than absolute levels, of amino-acids determines the response to different amounts of dietary protein and to amino-acid supplementation of the laying diet There was also evidence that egg size may be modified quickly by altering dietary amino-acid balance The following experiment was designed to test the validity of these observations

Forty-eight White Leghorn laying pullets, 8 months of age, were placed in individual laying cages The percentage composition of the basal diet (1) fed was ground wheat 69 09, ground yellow corn 10 0, soy-bean oil meal (44 per cent protein) 7 5, distillers' dried solubles 2 0, iodized salt 0 35, feeding oil (2,250 U S P units vitamin A, 300 I C U vitamin D_3/g) 0 5, vitamin B_{12} premix (20 mg/lb) 0 06, stabilized animal fat 5 0, bonemeal 1 75, limestone 3 75, manganese sulphate 0 015. The other diets consisted of the basal diet supplemented with amino-acids as follows (2) 0 25 per cent L-lysine monohydrochloride plus 0 25 per cent DL-methionine (98 per cent pure), (3) 0 255 per cent glycine, (4) 0 25 per cent L-lysine monohydrochloride plus 0 25 per cent DL-methionine plus 0 255 per cent glycine. The basal diet contained 14 per cent protein

Table 1

Treatment*	Effect of lymphocyte count	No of animals	Survival of skin grafts (days)	
			Individual values	Mean
Nil	Nil	12	8, 8, 8, 8, 8, 8, 8, 8, 8, 8, 8, 9	8
Lymph drainage from day −5 to day 0	Fell during drainage period to about half initial level, began to rise 1 week later but still below normal by time all grafts destroyed	10	11, 11, 11, 12, 12, 13, 14, 15, 15, 15	13
Antilymphocytic serum 1 ml /day i p on days +1 to +14 inclusive	Fell during period of treatment to about quarter initial level, then slowly increased	10	11, 11, 12, 14, 14, 14, 14, 16, 18†, 41	16
Antilymphocytic serum 2 ml /day i p on days −7 to −1 inclusive, and 1 ml /day i p on days +1 to +14 inclusive	Fell during pre-grafting treatment to about one-fifth initial level, then gradually increased for 13 days after which it fell again	10	18, 18, 22, 27, 29, 30, 30, 32, 32, 46	28
Normal rabbit serum 2 ml /day i p on days −7 to −1 inclusive, and 1 ml /day i p on days +1 to +14 inclusive	Increased slightly throughout period of treatment	10	8, 8, 8, 8, 8, 8, 8, 8, 8, 8	8
Lymph drainage from day −5 to day 0 Antilymphocytic serum 1 ml /day i p on days +1 to +14 inclusive	Fell during period of treatment to about one-tenth original level, then gradually rose and was almost normal 3 weeks after grafting	10	17, 18†, 22†, 26†, 33, 38, 42, 45, 54, 60	35

* The day of skin grafting is reckoned as day 0 † Animal died with healthy graft

Table 1 EGG PRODUCTION AND ANALYTICAL DATA

Diet	Amino-acid supplement	Group	Period	Production (%)	Av egg wt (g)
1	None	*A*	1	77.4	56.4
		B	2	62.9	56.4
		A	3	62.2	56.6
		B	4	62.5	57.4
2	Methionine + lysine	*B*	1	76.5	57.2
		A	2	64.3	57.6
		B	3	67.4	58.4
		A	4	65.1	58.3
3	Glycine	*C*	1	76.8	55.0
4	Glycine, methionine-lysine	*C*	2	61.3	56.0
3	Glycine	*C*	3	58.5	55.7

The pullets were divided into 3 groups of 16 birds each, distributed in individual laying cages so as to effect uniformity of environmental factors The three groups of birds were subjected to the dietary régimes indicated in Table 1 and Fig 1 Groups *A* and *B* alternated between diets (1) and (2) Group *C* alternated between diets (3) and (4)

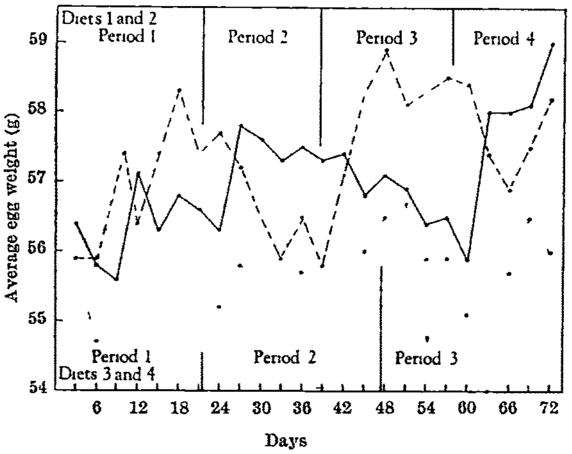

Fig 1 Average weights of eggs laid by birds fed diets of different amino-acid balance —, Group *A*, – – –, group *B*, , group *C*

Individual daily record was kept of the weights of eggs laid by the birds within each group The experiment was of 72 days' duration The weights of the component parts (shell + shell membranes, albumen and yolk) of all eggs laid on 20 days during periods 3 and 4 were determined The moisture content of the albumen from several days' production of eggs was also determined during the last period

The average weights of the eggs laid are shown in a graph by 3-day periods in Fig 1, and a summary of the results is given in Table 1 The rank of the diets in their effect on egg size was similar throughout the experiment· diet (2), diet (1), and diet (3) or (4)

Since egg size was depressed when glycine was added to the basal diet and as supplementation with lysine and methionine increased egg size, it may be concluded that amino-acid balance and not protein-level was the factor limiting egg size Supplementation with lysine and methionine of the diet already supplemented with glycine, that is, substitution of diet (4) for diet (3), did not increase egg size to the weight of the eggs laid by birds receiving diet (2), which was supplemented with lysine and methionine only Evidently, in the case of diet (4), although the absolute levels of lysine and methionine were similar to those in diet (2), the levels of these amino-acids relative to the over-all amino-acid composition of the diet were not optimum for maximum egg size.

When lysine and methionine were either added to or withdrawn from the basal diet, size of the eggs laid was affected on the fourth day following modification of the diet Alternation of diets (1) and (2) between groups *A* and *B* produced alternation in the relative size of eggs laid by the birds in the two groups

Table 2 COMPOSITION OF EGGS LAID BY BIRDS FED DIFFERENT DIETS

	No of eggs analysed	Av wt of eggs (g)	% of total weight shell	yolk	albumen	No of eggs analysed	% solids in albumen
Group *A*							
diet 1	121	56.5	9.11	28.04	62.83		
2	70	57.9	8.88	27.91	63.12	49	12.3
Group *B*							
diet 1	69	57.4	9.12	28.26	62.62	45	12.2
2	139	58.2	8.87	27.65	63.48		
Group *C*							
diet 3	146	55.5	9.02	28.96	62.03	35	11.9

The percentage composition of the eggs analysed is shown in Table 2 The percentage of albumen was greatest in the eggs laid by birds fed diet (2), followed in order by eggs laid by birds fed diets (1) and (3) The percentage of solids in the albumen was significantly ($P < 0.01$) lower in the eggs laid by the birds fed diet (3)

Infra-red Spectra of Embryonic Chick Feathers

THE demonstration by Bell and Thatachari[1] of sequential changes in the X-ray diffraction pattern of embryonic chick feathers from 'immature' to 'mature' β-keratin has suggested that the nature of this metamorphosis might be further revealed by infra-red spectra of the developing feather. The infra-red spectrum of embryonic feather has not been described, to our knowledge

Whole or homogenized washed feathers from the mid-dorsal region of white Leghorn chick embryos from the twelfth to nineteenth days of incubation were examined in

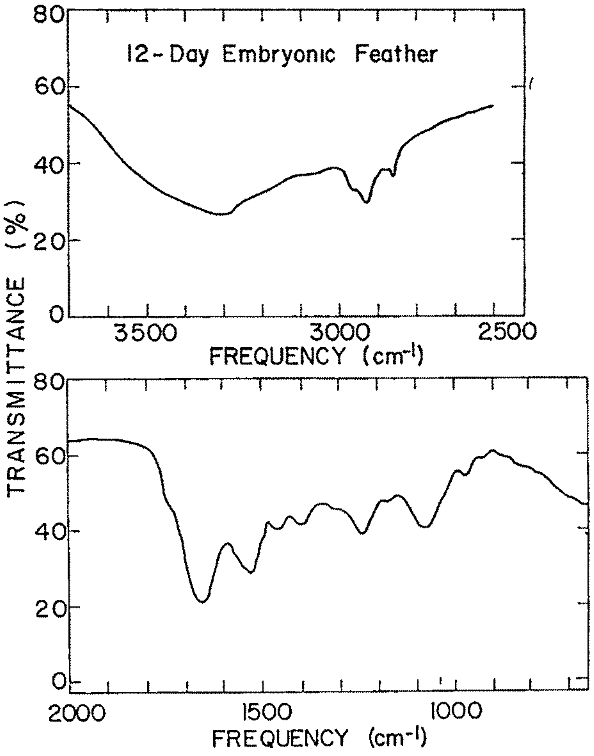

Fig 1 Infra-red spectrum of 12-day feather

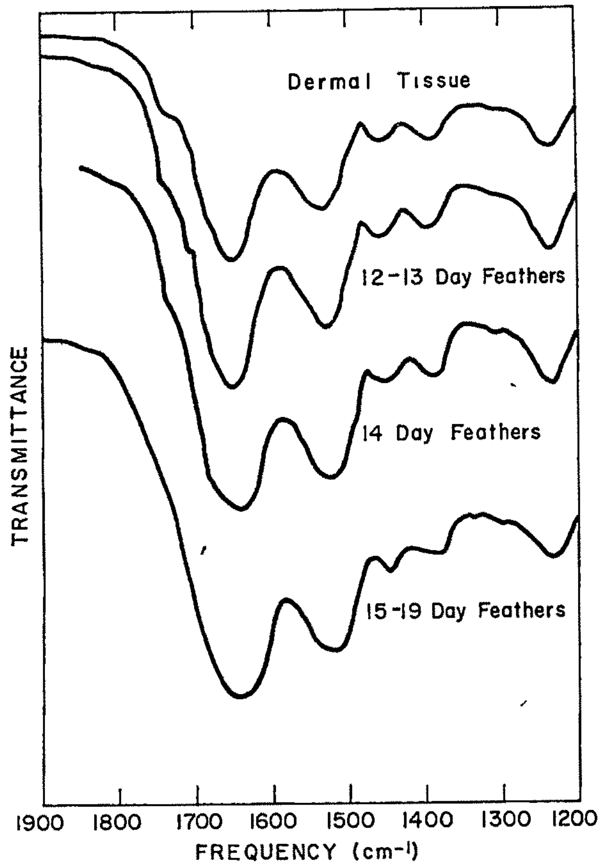

Fig 2 Loss of carbonyl-ester band during embryogenesis

a Perkin-Elmer double-beam infra-red spectrophotometer, model 421. Samples were usually prepared as potassium bromide pellets, but whole feathers pressed between sodium chloride plates and suspended in 'Fluorolube' were also examined to eliminate the possibility of artefacts caused by grinding and pressing Dermis, as subcutaneous tissue, and ether-extracted feathers from 13-day embryos were similarly studied

A representative spectrum of 12-day feather from 4,000 cm^{-1} to 700 cm^{-1} and spectra in the 1,800–1,200 cm^{-1} range for all specimens examined are shown in Figs 1 and 2, respectively In general, the patterns are similar both to each other and to those reported for adult swan and eagle quill[2,3] and are characteristic of class *B* proteins[3] The significant change seen during embryogenesis is that the pronounced shoulder at 1,730 cm^{-1} on the high-frequency side of the amide I band observed in 12- and 13-day specimens is decreased at 14 days and gone thereafter This shoulder, which lies in the region of ester-carbonyl absorption, is quite prominent in dermis, much diminished in ether-extracted 13-day feathers and not present in native collagen[4]

These results suggest that the structural changes detected by X-ray diffraction during embryogenesis of the feather are of a sort not readily detected by infra-red spectroscopy and that the changes are explicable by differences in molecular orientation rather than by appearance of new chemical groupings Disappearance of the band at 1,730 cm^{-1} is probably a manifestation of retraction of the mesodermally derived feather core but could also be consequent in part on loss of lipid from other cells during development

Reversed Diurnal Vertical Migration of Planktonic Crustacea in Inland Waters of Low Hydrogen Ion Concentration

EXPERIMENTAL investigations[1,2] have shown that pH has an influence on the vertical migration of planktonic crustaceans In particular it has been demonstrated that tactic responses at a pH of 9 0 may be in the reverse direction to those at a pH of 7 0 However, little attention has been directed to the fact that such reversed responses may occur under natural conditions of high pH

A reversed diurnal vertical migration was recently reported[3] for 2 species of planktonic crustacea in a New Zealand lake with a high pH No causal relationship between the high pH and the unusual pattern of migration was suggested in this report However, it was afterwards discovered that of the very few previous reports of such migratory behaviour in inland waters[4-6], one[6] was concerned with an African lake which showed a striking similarity to the New Zealand one with respect to pH and the relative proportions of the major inorganic ions (Table 1) The main chemical difference is that Lake Rudolf is 5–6 times more concentrated and has a greater proportion of sulphate than Lake Aroarotamahine. A further similarity is that both lakes are relatively opaque with a limit of visibility between 2 and 3 m Worthington and Ricardo[6] stated "The most striking fact is that the migration (of *Diaptomus banforanus*) appears to be the reverse of the normal . .", and mentioned the possibility that high pH might account for the aberrant behaviour The significance of their observation appears to have been somewhat overlooked

Table 1 CHEMICAL COMPARISON OF REVERSED MIGRATION LAKES

	Lake Rudolf Rift Valley Central Africa[9]	Lake Aroarotamahine Mayor Island New Zealand (Feb 1963)
pH	9 5	9 0
Alkalinity	0 020 N	0 0035 N
Na^+	770 mg/l	125 mg/l.
K^+	23	4 0
Ca^{++}	5 0	0 9
Mg^{++}	4 0	1 2
$SO_4^=$	56	4
Cl^-	429	76
$CO_3^=$	181*	10
HCO_3^-	958*	193
Total CO_2	830	147
Reversed migrants	*Diaptomus banforanus*[6]	*Boeckella propinqua* (C VI ♂♂) *Daphnia carinata*[3]

* Calculated from pH and stated value [9] for CO_2

The chemical results shown in Table 1 for Lake Aroarotamahine were obtained from the analysis of a surface sample. The values stated for pH, $CO_3^=$ and HCO_3^- were obtained from field measurements made immediately after taking the sample. The pH of this lake is, of course, subject to considerable seasonal and vertical variation During summer when thermal stratification is well developed the zooplankton is limited to the epilimnion where the pH is not less than 9 0 During winter the lake is in a state of complete circulation and the pH is approximately 8·2 throughout. *Daphnia carinata* showed a reversed migration under both these conditions, but in the case of *Boeckella propinqua* males there was no evidence of reversed migration during the period of complete circulation.

Lake Rudolf and Lake Aroarotamahine are both associated with alkaline rhyolites in the form of either comendites or pantellerites[7,8] which are rich in sodium and potassium but very poor in calcium and magnesium. As a result of the chemical weathering of these rocks relatively large amounts of extremely soluble sodium carbonate have found their way into these lakes, so that they have come to contain a sodium carbonatochloride water in which alkaline earth and sulphate ions are present in only very small proportions.

It is interesting to note that the very low calcium content of the lakes mentioned here is not a limiting factor with respect to zooplankton productivity. On the contrary, there is evidence that both lakes are highly productive. In a series of 4 lakes, Worthington and Ricardo[6] found the zooplankton numerically richest in Lake Rudolf. Likewise Bayly[3] found far greater zooplankton densities in Lake Aroarotamahine than in 9 other lakes examined.

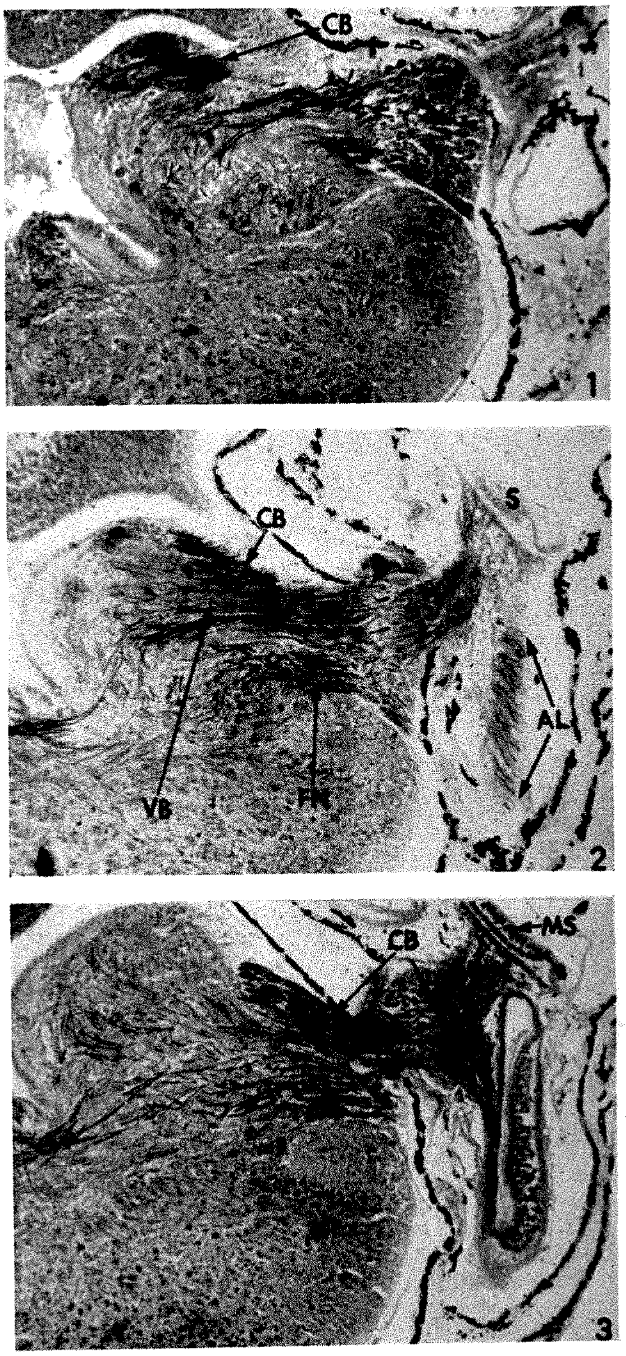
Posterior Division of the Eighth Cranial Nerve in *Lacerta vivipara*

Little information is available in the literature on the innervation of sensory areas in the inferior, or saccular, portion of the inner ear of the lizard. In order adequately to show nervous structure, histological techniques have been used in the past that preclude dealing with the intact animal; usually the brain must be removed, thereby disrupting anatomical relationships. A notable exception is the work of Beccari[1] on embryonic material of *Lacerta*; his primary interest, however, was in finding homologies in the central nervous system between reptiles and mammals, and he gives little consideration to the central terminations of fibres from specific sensory areas. Weston[2,3] has speculated on central terminations of sensory fibres in *Sphenodon* and has discussed structure of vestibular and auditory areas in brains of a number of reptiles.

Serial sections through the inner ears of two de Castro-stained specimens of *Lacerta vivipara* were available for examination, and de Castro-stained specimens of *Anniella pulchra* and *Anguis fragilis* were available for comparison, along with Bodian-stained serial sections of the inner ears in *Gongylus ocellatus*, *Calotes versicolor* and *Sceloporus undulatus*.

Nerve fibres from the macula of the utricle and cristæ of the anterior and lateral ampullæ project to the central nervous system through the anterior acoustic foramen and terminate rostral to the central projections of the remaining sensory areas (Fig. 4).

Of interest here is the qualitative difference in the posterior division of the VIIIth cranial nerve between fibres which project to the dorsal, acoustic area of the brain stem, and those that project ventrally to the vestibular areas of the brain stem.



Figs. 1, 2 and 3. Cross-sections through the inner ear in *Lacerta vivipara*, anterior to posterior, to show the course of the cochlear bundle and relationships between the sensory areas of the membranous labyrinth and the central nervous system. (For key to abbreviations see legend to Fig. 4)

Fibres which originate in the anterior, lagenar, portion of the cochlear duct (Fig. 2) and from the basilar papilla course posteriorly in the otic capsule to emerge from the capsule (via the posterior acoustic foramen) and, as a distinct, dark-staining bundle, cross caudal to fibres that arise from the macula of the saccule (Fig. 3). The bundle courses dorsally and rostrally within the central nervous system to terminate on small cells in the acoustic area of the brain stem (Fig. 1). For convenience, this group of fibres is termed the cochlear bundle.

The fibres projecting from the macula of the saccule, joined by those from the papilla neglecta of the utricle and crista of the posterior ampulla, terminate ventral to the termination of the cochlear bundle. The cells in the vestibular area with which these fibres synapse are larger

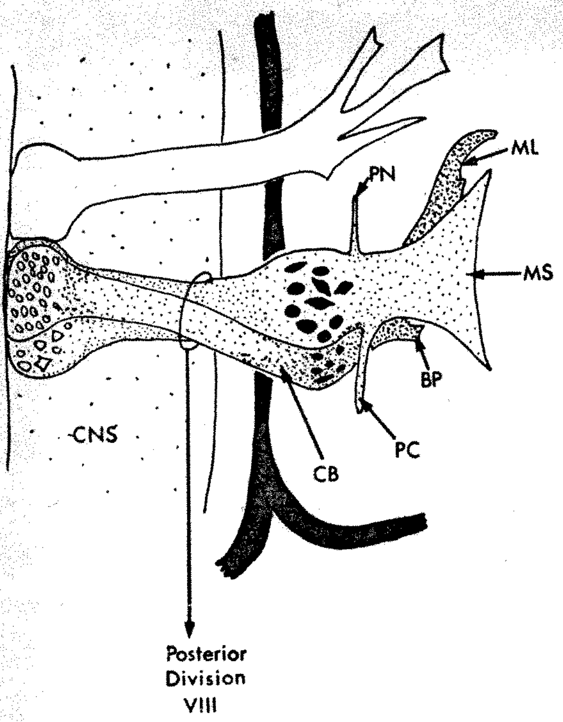


Fig. 4. Schematic representation of the course and relationships of the fibres of the posterior division of the VIIIth cranial nerve in *Lacerta vivipara*. The anterior division of VIII, with ramifications from the utricle, and anterior and lateral ampullæ, is shown in white.

AL, anterior, lagenar, part of the cochlear duct; *BP*, basilar papilla; *CB*, cochlear bundle; *CNS*, central nervous system; *FN*, facial nerve; *ML*, macula of the lagena; *MS*, macula of the saccule; *PC*, posterior crista; *PN*, papilla neglecta; *S*, saccule; *VB*, vestibular part of the posterior division of VIII

than those associated with the cochlear bundle (Figs. 1 and 2).

These relationships are shown schematically in Fig. 4. In *Lacerta*, then, the central terminations of fibres from the macula of the lagena are the same as those from the basilar papilla, and different from those of the macula of the saccule. A reasonable conclusion from the structural evidence in *Lacerta* is that the macula of the lagena has some auditory function, while the macula of the saccule is concerned mainly with equilibration.

This is not the case in forms in which sensory areas in the cochlear duct are reduced relative to the macula of the saccule, such as in *Anniella* and *Anguis*. In the latter specimens, there is no secondary tympanic membrane, and it is probable that these lizards do not hear as well as free-living forms, such as *Lacerta*, in which a well-defined secondary tympanic membrane is present. Other evidence (which will be published elsewhere) indicates that the inner ear in *Lacerta* is more highly evolved than that in either *Anniella* or *Anguis*, and it is possible that auditory function of the macula of the lagena is a phylogenetically advanced feature.

Action of Piperazine on the Neuromuscular System of *Ascaris lumbricoides*

PIPERAZINE is the drug most commonly used for the treatment of ascariasis, in preference to other anthelmintics, because it produces a flaccid paralysis of the parasites[1] rather than hyperactivity. Though no direct evidence was available, it was suggested that such paralysis might be due to a curare-like effect, since piperazine prevents the stimulating action of acetylcholine on *Ascaris* muscle[2].

The electrical activity of the somatic muscle cells of *Ascaris lumbricoides*, var. *suum*, has recently been examined in this laboratory[3] and we have now taken advantage of the techniques and preparations used in this work to investigate the action of piperazine on the neuromuscular system of the worm.

This system is represented in Fig. 1. Each somatic muscle cell is connected to one of the two nerve cords by a slender process, or muscle 'arm', which tapers down and divides into a number of branches or 'fingers'. The fingers from adjacent arms interlace, forming a closely woven network which, shaped as a thin ribbon, runs parallel to the nerve cord. Although little is known about the fine structure of this network, experimental evidence[3] has shown that it behaves as a functional syncytium, the individual muscle cells being electrically interconnected at this level.

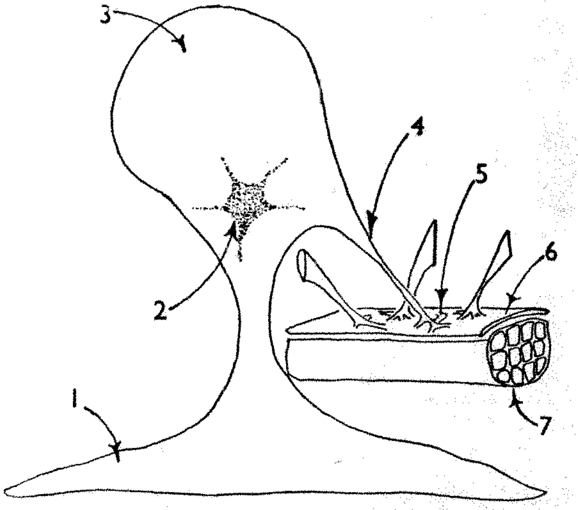

Fig. 1. Highly diagrammatic representation of the neuromuscular system of *Ascaris lumbricoides*. Only one complete muscle cell has been drawn, and the arms of three others; see text. It should be pointed out that the 'arm' of the muscle cell forms a right angle with the 'spindle', the latter being parallel to both the nerve cord and the longitudinal axis of the worm
1, Spindle; 2, nucleus; 3, nuclear bag or 'belly'; 4, arm; 5, fingers; 6, syncytium; 7, nerve cord

The complex formed by the nerve cord and associated syncytium has many of the properties of vertebrate smooth muscle, including that of autorhythmicity or automatic production of spike potentials. Microelectrode recording from the muscle cell 'bellies' shows a resting potential (average value about 30 mV) interrupted by rhythmic spike potentials, see Fig. 2*A*, which originated at the syncytium and are conducted along the arms and bellies to the spindles—the only part of the muscle cell which contains contractile material.

When piperazine citrate, as a solution adjusted to *p*H 7, is added to the saline bathing the *Ascaris* preparations (30 per cent sea-water) the amplitude of the spontaneous spike potentials is seen to decrease until the cells become electrically silent (Fig. 2). This effect is accompanied by an increase in the resting potential. In one experiment, for example, an average resting potential of 28·3 mV was increased to 41·0 mV on the addition of piperazine to the bathing solution to a final concentration of 10^{-4} (w/v). Increments of up to 15 mV have been observed when recording continuously from a belly.

In many cells the increase in the resting potential is concomitant with a considerable reduction in the frequency of the spike potentials, though in others the spikes disappear before any marked changes in their frequency can be detected. Often, the resting potential is seen to go on increasing after the spike activity is blocked.

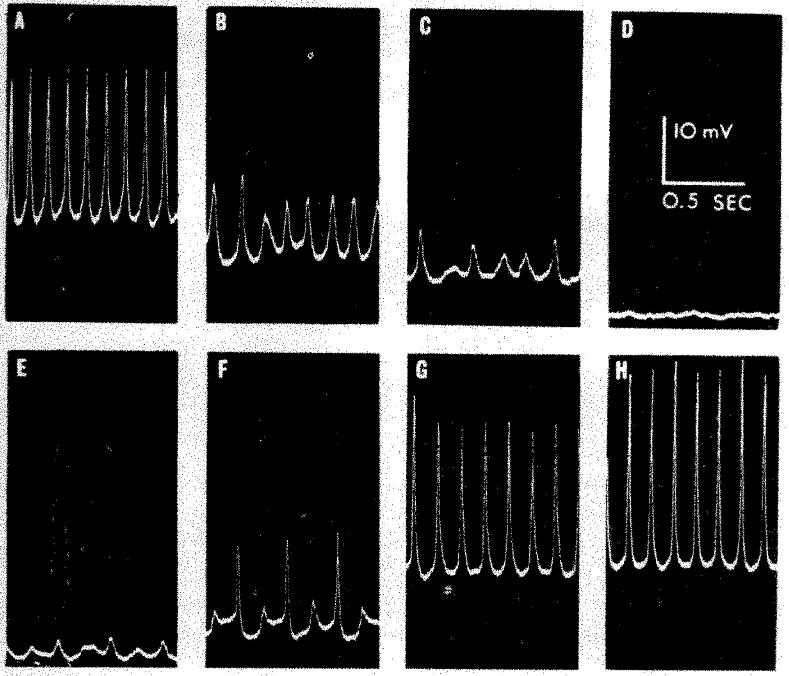

Fig. 2. Intracellular recordings illustrating the action of piperazine on the resting potential and spontaneous spikes of a somatic muscle cell of *Ascaris lumbricoides*. The microelectrode was inserted into the cell 'belly'. Between records *A* and *B* piperazine citrate was added to the bathing solution to a final concentration of 10^{-4} (w/v). Record *D* was taken about 5 min after record *B*. Between records *D* and *E* the piperazine was washed out of the chamber. The records are arranged in each row, so that the relative position of the traces shows actual changes in membrane potential which was, approximately, 29 mV in *A* and *H*, and 41 mV in *D* and *E*

Control experiments, in which equivalent amounts of sodium citrate were added to the bathing solution, showed that the effects described here are not due to the citrate anion, nor to a lowered concentration of calcium ions. As can be seen in Fig. 2, all the effects of piperazine are easily reversed by washing the preparation with fresh saline.

The action of piperazine on *Ascaris* muscle appears to be similar to that exerted by inhibitory transmitters and pharmacological analogues on the transmembrane potential of smooth and cardiac muscle cells. This resemblance is particularly interesting since it has been shown that the nerve cord of *Ascaris* does contain a system of muscle inhibitory fibres. Goodwin and Vaughan Williams[4] have recently reported that high-frequency electrical stimulation of the nerve ring situated in the pharyngeal region of the worm results in an inhibition of both the spontaneous contractions of the body and those elicited by local stimulation of motor nerves.

Our experiments have shown that inhibitory fibres can also be stimulated in fragments of *Ascaris* which do not include the nerve ring by electric shocks applied to the ventral nerve cord. Marked hyperpolarizations of the muscle cell membrane, accompanied by a block of spike activity, can be observed following single stimuli while recording from the belly (Fig. 3). Repetitive stimulation of the inhibitory fibres increases the resting potential of the bellies to a steady level from 40 to 45 mV.

Piperazine does not interfere with the function of the inhibitory fibres. On the contrary, small concentrations of this compound increase the effectiveness of inhibitory stimulation, and small inhibitory potentials can still be recorded from hyperpolarized cells in paralysed preparations.

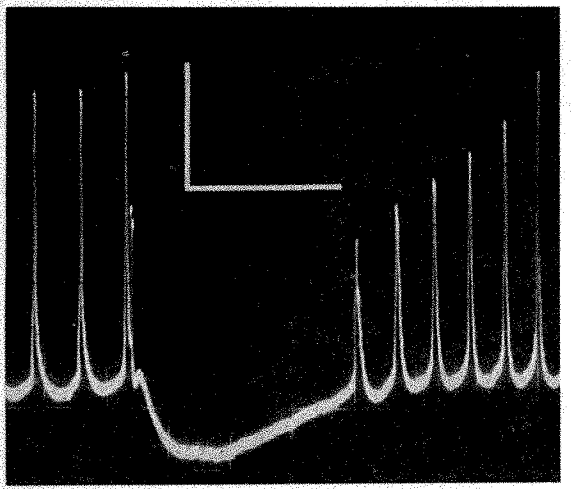

Fig. 3. Effects of the electrical stimulation of inhibitory nerve fibres in the nerve cord of *Ascaris lumbricoides*. Two pulses were applied to the nerve cord at the points marked by the artefacts. They resulted in a hyperpolarization of the muscle membrane and the blockade of the spontaneous spike potentials. Records were taken with a microelectrode inserted into the cell belly. Calibrations: vertical, 10 mV; horizontal, 0·25 sec

Gaseous-ion-induced Stimulation of Cytochrome *c* Biosynthesis

IN earlier papers we described the growth acceleration observed when seedlings of *Avena sativa*, *Hordeum vulgaris* and *Lactuca sativa* were exposed to air ions[1-3]. (+) or (−) Ions generated in pure air produced statistically significant increases in stem-length, integral elongation and wet and dry weight. The degree of growth stimulation roughly paralleled ionic density and was accompanied by a proportional increase in flow of current to ground. Analysis of ion-treated plants showed no deviation from normal composition. This communication presents evidence that gaseous ions stimulate the biosynthesis of cytochrome *c*.

Germinated seeds of *Hordeum vulgaris* (Dayton Winter and California Mariout) with roots 1–2 cm long but without coleoptiles were grown in an iron-free chemically defined nutrient solution. The details of the plant culture system and radioisotopic generators used are described elsewhere[4]. The essential points are: units of 36 seedlings each were exposed to (+), (−) or (0) air ions in clear plastic chambers under greenhouse conditions. The greenhouse was supplied with air purified by passage through an electrostatic precipitator and an activated carbon filter. The minimum temperature was 25° C, but maximum temperature varied with the season. The volume of solution was

Table 1. EFFECT OF UNIPOLAR IONIZED AIR ON DEVELOPMENT OF IRON CHLOROSIS IN SEEDLINGS OF *Hordeum vulgaris* GROWN IN CHEMICALLY DEFINED IRON-FREE NUTRIENT SOLUTION. THERE WERE 36 PLANTS IN EACH TEST GROUP AND THE ANALYTICAL DATA OF 3 SEPARATE EXPERIMENTS PERFORMED DURING THE SUMMER HAVE BEEN AVERAGED

kept constant by addition of distilled water. Ion levels were regularly monitored and were maintained at > 3·1–3·8 × 10^5 (+) or (−) ions/cm²/sec at the tops of the seedlings. Planters were rotated in position to avoid effects due to variations in incident light. At intervals after starting exposure of the seedlings to ions, samples were removed for analytical studies. Their content of cytochrome *c* and chlorophyll was determined and the cytochrome *c* fractions were analysed for protein and for iron content[5–8].

Seedlings cultivated under these conditions in a normal atmosphere developed iron chlorosis. In the presence of (+) or (−) ionized air chlorosis developed earlier and the production of cytochrome *c* was accelerated (Table 1). Thus at 7 days, although the leaves were normal in appearance, the ion-treated plants had only 80 per cent as much chlorophyll as the untreated plants, but 160 per cent as much cytochrome *c*. From the twelfth to the twentieth day all the leaves showed pronounced chlorotic changes; the [chlorophyll] in the ion-treated plants was 50 per cent and the [cytochrome *c*] 120 per cent of the corresponding values obtained in untreated plants. At this time iron was added to the nutrient solution and the plants recovered rapidly from chlorosis. By the nineteenth–twenty-seventh day the leaves in all three groups appeared normal and there was good agreement in [chlorophyll] values. Nevertheless the plants exposed to (+) or (−) ions contained nearly 210 per cent as much cytochrome *c*/g as the plants grown in a normal atmosphere. Substantially the same results were obtained in two additional experiments performed during the autumn and winter months. While the development of severe chlorosis was slower recovery after adding iron was just as fast.

A separate experiment was performed growing the seedlings in a sand substrate with an iron-containing chemically defined medium (Table 2). Here no chlorosis developed in any of the plants, and the only gross effect was the characteristic ion-induced acceleration of growth.

Table 2. EFFECT OF UNIPOLAR IONIZED ATMOSPHERE ON CYTOCHROME *c* AND CHLOROPHYLL CONTENT OF *Hordeum vulgaris* SEEDLINGS GROWN IN SAND CULTURE WITH CHEMICALLY DEFINED NUTRIENT SOLUTION CONTAINING 2·5 P.P.M. IRON. A TOTAL OF 20 PLANTS WAS USED IN EACH EXPERIMENTAL GROUP. EXPOSURE PERIOD 20 DAYS

Cytochrome *c* of the ion-treated plants was double that of the controls.

The cytochrome *c* fractions prepared from the plants contained small amounts of other extractable substances. Accordingly, the percentage change in [cytochrome *c*] for a given sample displays only approximate agreement among the three criteria used; namely, absorbance at 550 mμ, [cytochrome *c* protein] and [cytochrome *c* iron].

The simplest explanation of the experimental results described here appears to be that when a seedling grows in an iron-free environment air ions cause most of the limited store of iron present in the seed to be diverted to the synthesis of cytochrome *c*. Accordingly not enough iron is available to support the normal biosynthesis of chlorophyll and chlorosis develops rapidly. If iron is present in normal amounts in the substrate, exposure to ionized air results in typical ion-induced increase in growth rate associated with an increased production of cytochrome *c* but without hampering chlorophyll production. The supply of iron evidently is sufficient to provide for both biosynthetic processes and chlorosis is avoided. The increased [cytochrome *c*] may represent an important metabolic factor in making possible the accelerated growth rate regularly observed in ionized air.

MICROBIOLOGY

Nitrogen Fixation in Cell-free Extracts of *Azotobacter vinelandii* prepared by Lysis with Phage A_{22}

WITHIN the past few years nitrogen fixation has been achieved in cell-free extracts of micro-organisms including *Clostridium pasteurianum*, *Azotobacter vinelandii*, *Bacillus polymyxa*, and in a variety of blue-green algae[1-5]. We now report that cell-free lysates of *A. vinelandii*, prepared by adding A_{22} phage[6] to cultures of the bacteria during early exponential growth, incorporate nitrogen gas.

A. vinelandii OP was grown in 4-l. aerated cultures in Burk's nitrogen-free medium at 30° for 12 h. At this stage when cell counts were about 2×10^7 cells/ml., A_{22} phage was added (phage to cell input 3:1) and incubation continued for another 6 h. Phage counts of the incubated cultures, made on agar plates layered with *Azotobacter* cells in a nitrogen-free medium, showed more than a 100-fold increase in phage plaque-forming units per ml. The lysed material was collected at 44,000*g* in a continuous-flow Servall centrifuge at 4°, and the residue was washed three times with 0·05 M phosphate (*p*H 7·5). The residue suspended in the dilute phosphate buffer was recentrifuged at the various *g* values shown in Table 1. Less than 10^3 cells/ml. were found by plate counts of the suspended residue. Before exposing to the nitrogen-15 gas mixture the pellets collected at various *g* values were suspended in 0·05 ml. phosphate buffer *p*H 7·5. The effects of adding medium from 6-h cultures, from which the bacteria had been removed by centrifuging at 40,000*g* for 1 h (absence of whole cells checked by plating experiments) to supernatant fractions and to the suspended pellets were investigated. In some experiments the cell-free medium was boiled for 15 min, cooled and then added to the test fractions. Samples containing between 0·2 and 1·5 mg protein were exposed for 2 h in Warburg flasks to a gas mixture containing (atmospheres) 0·2 nitrogen, 0·2 oxygen and 0·8 helium. The nitrogen gas contained 33·4 atomic per cent nitrogen-15 excess. The extracts were then digested in sulphuric acid containing a copper-selenate catalyst. Total nitrogen was determined by the micro-Kjeldahl procedure and nitrogen-15 by the method of Simms and Cocking[7] using a mass spectrometer.

Table 1. NITROGEN FIXATION IN EXTRACTS OF *Azotobacter vinelandii* PREPARED BY LYSING CELLS WITH PHAGE A_{22}. ATOMIC PER CENT NITROGEN-15 EXCESS

	Sample	Exp. I	Exp. II
	Whole cells (12 h growth)	0·56	0·68
	Cell-lysates* centrifuged successively at the following *g* values:		
1	5,000*g* for 30 min (pellet)	0·007	0·025
2	(1) plus *M*†	0·009	0·030
3	5,000–14,000*g* for 30 min (pellet)	0·018	0·026
4	(3) plus *M*†	0·490	0·254
5	14,000–27,000*g* for 30 min (supernatant fluid)	0·028	0·032
6	(5) plus *M*†	0·380	0·540
7	27,000–44,000*g* for 60 min (residue)	0·029	0·034
8	(7) plus *M*†	0·240	0·340
9	44,000*g* for 60 min (supernatant fluid)	0·016	0·023
10	(9) plus *M*†	0·104	0·132

* Whole cells (12 h growth) treated with A_{22} phage and incubated for a further 6 h to effect lysis. Lysate collected at 44,000*g* suspended in 0·05 *M* phosphate (*p*H 7·5) and centrifuged successively at the various *g* values.

† *M*, medium from 6 h cultures of *Azotobacter* centrifuged at 40,000*g* for 1 h to remove whole cells. An equal volume of the medium added to the fractions.

The results in Table 1 show that there is little fixation in the cell-debris left after centrifuging the suspended residue at 5,000*g*; but the fractions collected at 14,000*g* or above have an appreciable enrichment of the isotope. The addition of the cell-free culture medium to the various fractions stimulated nitrogen fixation as reported earlier[3,5]. The main activity was found in the particulate fractions collected between 14,000*g* and 44,000*g* although there was an appreciable enrichment even in the resultant supernatant fraction. When the latter was centrifuged at 144,000*g* for 1 h the activity was found in the pellet. The stimulatory effect of the medium on nitrogen fixation was not destroyed by boiling.

It is of interest that electron paramagnetic resonance spectra of the active particulate fractions showed pronounced signals at gauss 1·94, presumably non-hæm iron, and at gauss 1·97, probably Mo^{5+}, as well as one for a flavin semiquinone. These results are similar to those reported for active nitrogen-fixing fractions prepared from *Azotobacter* by other methods[8].

Significance of Deoxyribonuclease Production by *Staphylococci*

METHODS of differentiating pathogenic species of *Staphylococci* (*Staphylococcus aureus*) from commensal strains (*Staph. albus*) are of prime importance to the medical bacteriologist. The method generally used to effect this separation is one of the many modifications of the coagulase test, and it is usually considered that new tests adopted for this purpose should correlate highly with the coagulase index. Among the alternatives that have been proposed to the coagulase test are colonial pigmentation, phenolphthalein phosphatase activity and the possession of a fibrinolysin.

None of these has found favour. Chromogenesis has been considered unreliable, partly because of the subjective difficulties involved, but the introduction of glycerol monoacetate agar by Willis and Turner[1] has done much to eliminate this problem. Further, this new medium permits a subdivision of epidemiological importance within the pathogenic group. Barber and Kuper[2] suggested that phosphatase activity paralleled coagulase production, but there is some disagreement about the value of this test because of the large number of coagulase-negative strains that produce a phosphatase. It was noted by Christie and Wilson[3] that the fibrinolytic activity of human strains of *Staphylococci* generally correlated with the coagulase test and with pathogenicity, but in our experience there are many important exceptions to this generalization.

More recently, Weckman and Catlin[4], using a viscometric technique, showed that high deoxyribonuclease production was a characteristic of coagulase-positive

Staphylococci, and suggested that this property might be of use in their identification. Other workers[5-7], using the plate method of Jeffries *et al.*[8], have produced some evidence in support of this view.

In work recorded here we have investigated the relation between staphylocoagulase production and a number of other physiological activities. Colonial pigmentation was determined on glycerol monoacetate agar[1], and phosphatase activity on a slight modification of the medium used by Barber and Kuper[2]. A modified heated horse blood agar and a new fibrin agar medium were devised to detect proteolysis and fibrinolysis. Deoxyribonuclease activity was studied on an agar medium containing a final concentration of 0·2 per cent of the sodium salt of thymus gland deoxyribonucleic acid (B.D.H.). This was not autoclaved before its incorporation into the sterile basal medium. Full details of the preparation and use of these media will be described elsewhere.

Table 1 summarizes the results of tests on 227 coagulase-negative *Staphylococci* and 1,467 coagulase-positive strains. Results of tests for the phosphatase activity of 333 of these strains are shown in Table 2.

Table 1. REACTIONS OF 1,694 STRAINS OF *Staphylococci* OF HUMAN ORIGIN ON VARIOUS MEDIA

Staphylococci	Deoxyribonuclease activity		Fibrinolytic activity		Pigment on monoacetate agar		Proteolysis on heated blood agar	
	+	−	+	−	+	−	+	−
Coagulase-positive	1,467	0	971	496	1,467	0	826	641
Coagulase-negative	5 (weak)	222	1 (weak)	226	1	226	8 (weak)	219
Total	1,694		1,694		1,694		1,694	

Table 2. PHOSPHATASE ACTIVITY OF 333 STRAINS OF *Staphylococci* OF HUMAN ORIGIN

Staphylococci	Phosphatase activity on phenolphthalein phosphate agar		Total
	Phosphatase positive	Phosphatase negative	
Coagulase-positive	106	0	106
Coagulase-negative	190	37	227
Total	296	37	333

Apart from phosphatase production, coagulase-negative *Staphylococci* showed little activity against any of the substrates tested. Thus, only 5 of the 227 strains produced detectable amounts of deoxyribonuclease and even these caused only a weak reaction. Similarly, only one strain showed any fibrinolytic activity and only 8 were even weakly proteolytic. All but one strain failed to produce pigment, the colonies being porcelain white on glycerol monoacetate agar.

In contrast, the coagulase-positive organisms were, in general, highly active against the substrates utilized. All strains tested split phenolphthalein phosphate, all produced deoxyribonuclease and all formed pigmented colonies on glycerol monoacetate agar. Fibrinolysis was displayed by 66·3 per cent while 55·2 per cent were proteolytic on the modified heated blood agar medium. Within the coagulase-positive group, however, there is a well-defined and commonly encountered sub-group of organisms which are non-fibrinolytic, non-proteolytic and non-phage-typable, and in these respects resemble the saprophytic species. These organisms form a yellow, rather than an orange, pigment on glycerol monoacetate agar, and despite their similarities to *Staph. albus* are often of more serious epidemiological concern than are other varieties of *Staph. aureus* (see Jacobs *et al.*[9], Willis *et al.*[10]).

These results show that phenolphthalein phosphatase production, fibrinolysis and proteolysis are of little determinative value in separating the pathogenic from the saprophytic species. Deoxyribonuclease is produced by all coagulase-positive *Staphylococci* but by only a few strains of the coagulase-negative group. Thus the test for deoxyribonuclease production, which is simple to perform, has a useful place in the diagnostic laboratory for the recognition of potential pathogens. The parallel observed between the apparently dissimilar coagulase and deoxyribonuclease activities warrants further investigation.

Although no definite statement can be made about the role of deoxyribonuclease production in staphylococcal pathogenicity, it is of interest that all strains regarded as potentially pathogenic produce this enzyme in additon to staphylocoagulase. The ability of a staphylococcus to destroy deoxyribonucleic acid would seem to be more closely linked to a mechanism of pathogenesis than its capacity to coagulate blood plasma, having regard to the wide distribution of deoxyribonucleic acid in the host body, and its fundamental importance in the living cell. It is well known that some strains of *Staph. albus* cause infections in man despite their inability to form coagulase. It may well be that these are representatives of a group that forms detectable deoxyribonuclease.

Vibrio cholerae and Colicines

COLICINES originally demonstrated in *E. coli* have since been found in many other Gram-negative bacilli present in the intestine, *Ps. pyocyanea* and some Gram-positive bacilli[1-4]. Such antibacterial substances are now called bacteriocines[5]. It has also been confirmed that bacteria of different genera may produce a similar colicine[6] and that the range of antibacterial activity of colicines exhibits interesting specificities[3,4]. The possible role of bacteriophages, colicines and other factors producing disintegration of vibrios with subsequent liberation of toxin has been postulated to explain the pathogenesis of cholera[7] which prompted this investigation into the colicinogenicity and colicine-susceptibility of 60 strains of *V. cholerae* (45 Inaba and 15 Ogawa) and 15 strains of El Tor vibrios. Sixteen standard colicinogenic strains producing different types of colicines and 4 colicine-sensitive indicator strains were kindly presented by Prof. P. Fredericq of the University of Liège.

Twenty-nine strains of *V. cholerae* and 4 strains of El Tor vibrios were tested for production of colicine against other members of the species by the technique of Shannon[8]. This technique was at first standardized with known colicinogenic indicator strains in sheep blood agar plates. For the remaining 31 strains of *V. cholerae* and 11 strains of El Tor vibrios, the stab-technique of Fredericq[3] was used, as he found the technique of perpendicular streaks of Shannon was suitable only for the very actively colicinogenic strains. Each strain was tested against other members of the species and also against the known indicator strains, namely, *E. coli*, φ of Gratia, B, C and K-12.

Standard colicinogenic strains of various Gram-negative bacilli producing 16 different types of colicines, namely, colicines *A–K*, *V*, S_1–S_4 were also tested for their antibacterial effect on these vibrios by the same technique of Fredericq.

None of these 60 strains of *V. cholerae* and 15 strains of El Tor vibrios was found to produce bacteriocine-like antibiotic substances against other members of the same species or against the known colicine-sensitive strains of *E. coli*. All the vibrios were also found not to be susceptible to the known colicines produced by the common intestinal organisms using the experimental methods eminently suitable for demonstration of colicinogenicity and colicine-susceptibility of *E. coli* and other Gram-negative bacilli.

Bhaskaran[9], working on recombination of *V. cholerae*, found strains with fertility factor (P^+ strains) producing plaque-like clearings when tested on strains without fertility factor (P^- strains) under his experimental conditions which was not due to phage. The possibility of the clearing being due to bacteriocine was suggested by Prof. Lederberg. Farkas-Himsley and Seyfried[10] found lysogenic streptomycin-sensitive strains of *V. cholerae* under conditions of reduced redox potential undergoing lysis and liberating a substance lethal to their streptomycin-resistant mutants when tested aerobically. This inhibiting substance has been called vibriocin by them, as they excluded the possibility of its being a phage.

In spite of these observations, there seems to be little justification for postulating the possible role of colicines in the pathogenesis of cholera in the light of the findings reported here. Moreover, the hypothesis of the relation between production of colicines and pathogenicity does not find much support from the extensive investigations of Halbert[11] on the relation of antagonistic coliform organisms to *Shigella* infections.

CYTOLOGY

Preservation of the Ultrastructure of Plant Cells using Glutaric Acid Dialdehyde as a Fixative

Recently, Sabatini *et al.*[1] reported the use of glutaric acid dialdehyde (glutaraldehyde) and other aldehydes as fixatives for electron microscopy. Excellent preservation of the submicroscopic structure of pancreas and muscle cells was obtained when the tissues were fixed in 6·5 per cent glutaraldehyde. It was stressed that the value of this fixative lies in its application to ultrastructural cytochemistry, since it permits stabilization of the structural components of the cell without inactivating many of the enzymes.

Carasso and Favard[2] discuss in detail the chemical mode of action of formaldehyde as a fixative. Addition-reactions between formaldehyde and proteins and nucleic acids involve sulphydryl and amino-groups. The formation of methylene bridges between adjacent molecules can take place and aids in the stabilization of the structure. The reactions between the other aldehydes and the structural components of the cell are probably similar to those observed with formaldehyde. Preservation of ultrastructure may well depend on the reactivity of specific groups in proteins and nucleic acids with the aldehyde and on the ability of the aldehyde to form stabilizing cross-linkages. Since glutaraldehyde is a dialdehyde it could form two types of cross-linking bridges, involving either one or both of the aldehyde groups. Similarity between the fixation mechanism of formaldehyde and glutaraldehyde is suggested by the inability of glutaraldehyde to fix lipids. Accordingly, the absence of all cellular membranes is the most striking feature of the specimens fixed with glutaraldehyde.

Root-tips from etiolated seedlings of *Zea mays* were excised and fixed at 4° C for various lengths of time (0·5–12 h) in an aqueous solution of 4 per cent glutaraldehyde buffered at *p*H 7·8 in 0·028 M sodium veronal and sodium acetate. In some of the experiments a post-fixation in similarly buffered 1 per cent osmium tetroxide was carried out for 30 min at 4° C. The tissues were embedded in 'Vestopal *W*' and thin sections were stained for 1 h with half-saturated uranyl acetate.

A low-magnification electron micrograph of a section through the apical meristem of a maize root fixed in glutaraldehyde is shown in Fig. 1*a*. Three structural components can be recognized in the prominent nucleus: the nucleolus, the chromatin and the interchromatic substance. All three are granular in structure, and at higher magnification fine filaments can be observed to connect the granules. The nuclear envelope is absent, but its former location is marked by the chromatin with which it was closely associated. Small vacuoles are present, but the tonoplast is absent. Electron-dense bodies which are 0·3–0·4μ in diameter are identified as proplastids (Fig. 1*a*). They have undergone shrinkage during the process of fixation, dehydration and embedding. The surrounding void which they formerly occupied does not contain ribosomes. Thin fibrils extend perpendicularly through this region connecting the proplastids and the surrounding cytoplasmic structures. Although the proplastids contract and appear denser, ribosome-like particles can be recognized within them. Sometimes these particles occur in rows suggesting their former association with membranous structures.

A mitochondrion and a portion of the surrounding cytoplasm are shown in Fig. 1*b*. The mitochondria in the cells of the apical meristem can be identified by the electron-transparent areas in their centre. The existence of similar electron-transparent areas has been reported previously in plant mitochondria fixed by other methods[3,4]. The cristæ are poorly preserved; their presence is indicated by amorphous material, which has been tentatively identified as the proteinaceous components of the membranes. In addition to the structures which are interpreted to be cristæ, the mitochondria also contain filaments and ribosome-like particles. It should be noted that, unlike the proplastids, no shrinkage of the mitochondria has occurred. This may well be related to a difference of the matrices of both organelles. In the cytoplasm ribosomes can be recognized. They occur in small clusters or in rows, which suggest the former existence of ergastoplasm. A unique feature is the denser appearance of the ribosomes which are in the vicinity of the vacuoles. This may be due to a greater inherent density, possibly resulting from a contraction, or to an increased uptake of uranyl acetate. Whether this reflects a functional difference is not known.

The membranous components of the cell organelles can be retained if the tissue is post-fixed for 30 min in buffered osmium tetroxide. As a result of this double fixation the aspect of the membranes and other structural components is similar to that obtained with a normal osmium tetroxide fixation. Such a post-fixation was used in cytochemical work after a specific treatment for enzyme localization or the extraction of structural components with enzymes. A treatment consisting of an initial fixation in glutaraldehyde for 1 h or longer, followed by an incubation period in a pH 7 buffer at 37° C for 2 h and a post-fixation in osmium tetroxide, did not result in any visible damage to the cell structure. Some damage was observed if the initial fixation was only 0·5 h.

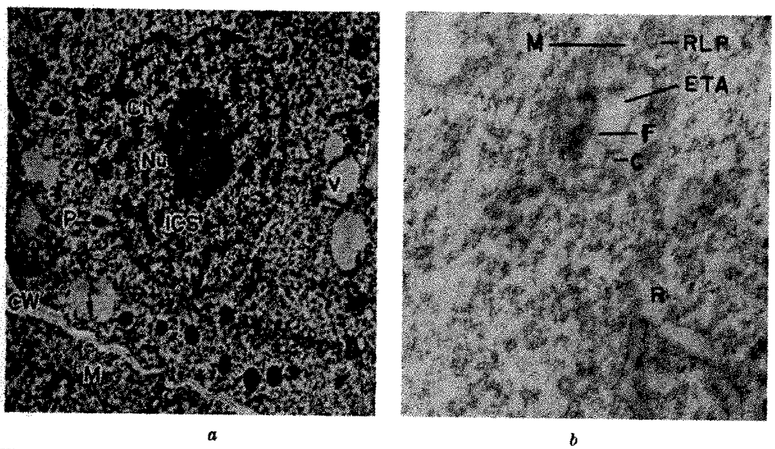

Fig. 1. Portion of a cell from the apical meristem of the root of ***Zea mays*** fixed for 2 h in 4 per cent glutaraldehyde buffered at pH 7·8. Thin sections were stained with half-saturated uranyl acetate for 1 h. *a*, Nucleolus (*Nu*); chromatin (*Ch*); interchromatic substance (*ICS*); vacuole (*V*); proplastids (*P*); mitochondrion (*M*); cell wall (*CW*). (× *c.* 6,600); *b*, ribosomes (*R*); mitochondrion (*M*) with electron-transparent area (*ETA*), crista (*C*), filaments (*F*) and ribosome-like particles (*RLP*). (× *c.* 30,000)

Cytochemical experiments revealed that the enzymes acid phosphatase, alkaline phosphatase and esterase are still active after a 90-min fixation in glutaraldehyde and can be localized in the tissue. The extraction of ribonucleic acid and deoxyribonucleic acid can be achieved with the corresponding nucleases after a fixation of 2 h. The Feulgen reaction can be applied to glutaraldehyde-fixed tissues embedded in 'Vestopal'. The interference of the fixative resulting in a light red background of the tissue does not affect the interpretation of the results. The removal of chromatin is complete in fixed specimens following a 3-h incubation period with deoxyribonuclease. Extraction of ribonucleic acid can also be achieved by treating the thin sections with 0·3 N potassium hydroxide at 37° C. After 3 h the ribosomes are completely removed and the electron density of the nucleolus is greatly decreased.

These preliminary results indicate that the ultrastructure of plant cells can be successfully preserved when glutaraldehyde is used as a fixative. Stabilization of the ultrastructure of the cell does not inactivate certain of the enzymes or prevent the extraction of some structural components. The interpretation of the cytochemical data is aided by a post-fixation with osmium tetroxide because it stabilizes the membranous structures and allows the structural components of the cell to be more readily recognized. It is believed that glutaric acid dialdehyde will be of considerable value for both cytochemical and structural studies of plant cells.

Mitosis in Metamyelocytes

The metamyelocyte of bone marrow is usually classified with the more mature forms of granulocyte[1] and is considered to be in the maturation fraction[2,3] rather than in the proliferative group of bone marrow cells. There are numerous reports that the metamyelocyte is unable to divide, and that mitosis is confined to less-differentiated forms of granulocyte[2,4-8].

Under certain experimental conditions, we have found evidence of labelling in metamyelocytes of guinea pig bone marrow exposed to tritiated thymidine for only short periods of time (not exceeding 1 h). The tritiated thymidine S.A. 360 mc./mM (Schwarz Biochemical Inc., New York) was injected either intravenously or into the peritoneum. During 30 min–1 h after the injection the animal was anæsthetized with ether and samples of femoral marrow were removed and washed in homologous serum. Bone marrow smears were prepared, air-dried and fixed in methyl alcohol. The films were covered with Kodak '*A.R.*10' stripping film and after three weeks' exposure they were developed. The smears were stained through the film with a 0·1 per cent solution of new methylene blue at pH 5·5.

Tritiated thymidine is incorporated into newly formed DNA (ref. 9), and since synthesis of DNA precedes mitosis our observation of this process in metamyelocytes suggests that these cells do in fact have a proliferative capacity. We have identified metamyelocytes labelled with tritiated thymidine in the bone marrow (Fig. 1 *a*, *b*, *c*, *d*) of guinea pigs three days after the onset of an acute anæmia due to loss of blood. In each animal approximately 12 ml. of blood was withdrawn and this caused the red cell count to fall from about 5,000,000 per c.mm. to approximately 2,500,000. Labelled metamyelocytes have also been seen in the bone marrow of young guinea pigs recovering from sub-lethal whole-body γ-irradiation[10]. Apart from the experimental conditions, labelling has been seen in metamyelocytes of normal bone marrow.

Cronkite *et al.*[11] used tritiated thymidine to study the proliferation of hæmopoietic cells and found that labelling in metamyelocytes did not appear until three hours after the injection. They concluded that the metamyelocyte is a non-dividing cell. In our investigations of anæmic and irradiated guinea pigs the labelling of metamyelocytes occurred within 1 h of injecting the label. This interval[12] excludes the possibility that the metamyelocytes are labelled because they are the daughter cells of labelled progenitors. The possibility is also excluded by the absence of labelled mitotic figures in the smears (Fig. 1*e*).

The presence of mitotic figures in metamyelocytes would provide additional evidence that these cells can in fact divide. These figures would have to be observed at a very early stage of mitosis when the typical shape of the metamyelocyte nucleus, as seen in the non-dividing cell, is still present. Figures of this type are rarely seen since the duration of this phase appears to be very short. In the later stages of mitosis when the shape of the metamyelocyte is lost, it would be virtually impossible to distinguish between a myelocyte or a metamyelocyte in mitosis. A metamyelocyte nucleus in an early stage of division is illustrated in Fig. 1*f* and its shape may be compared with that of the resting nucleus shown in Figs. 1 *a*, *b*, *c*, *d* and *g*.

How may the present findings be interpreted? It could be suggested that the label is taken up by cells which are myelocytes at the time of uptake but that they differentiate into metamyelocytes in the short interval

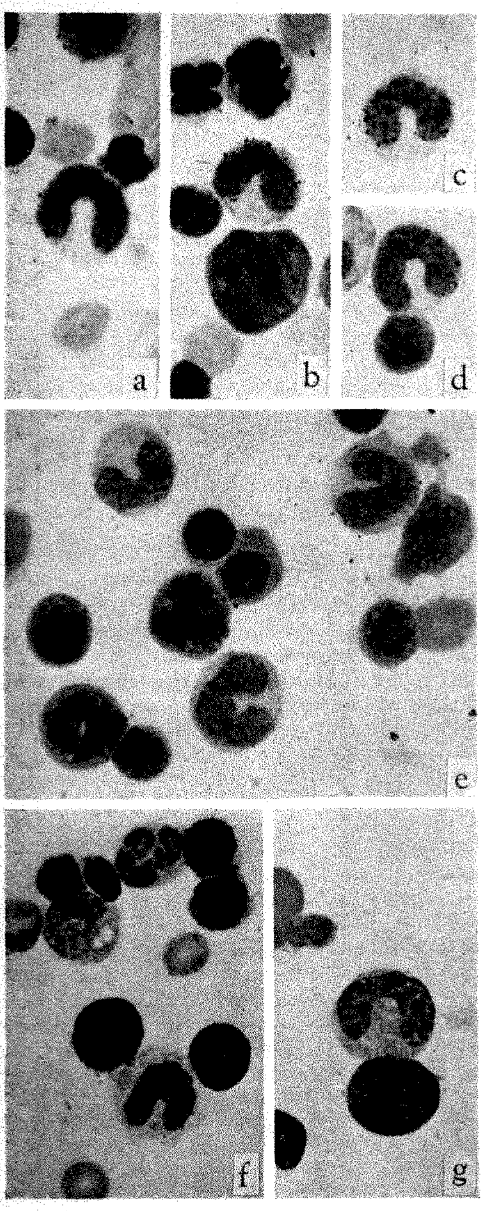

Fig. 1. *a, b, c, d*, Metamyelocytes in smears of guinea pig bone marrow labelled with tritiated thymidine; *e*, absence of labelling in mitotic figures; *f*, a metamyelocyte nucleus in an early stage of division; *g*, metamyelocyte nucleus in resting phase. *a, b, c, d, e*, Cells stained new methylene blue; *f, g*, cells stained MacNeal's tetrachrome. (× *c*. 1,166)

between injection of the label and the preparation of marrow smears. In the experiments recorded here, assuming that there is an immediate uptake of thymidine, the maximum time available for this differentiation would be no more than 1 h. This transformation appears to be improbable from the studies of Patt and Maloney[13], who found that approximately 11 h are required for the transition of a myelocyte into a metamyelocyte in the dog.

It might also be suggested that the evidence of proliferation in metamyelocytes has chiefly been seen under conditions which call for an increase in the production of cells. In these circumstances, if there is a common progenitor for both granulocytes and red cells, there might be competition for a basic stem cell. In the anæmic animals there would be a considerable demand for stem cells to differentiate into the erythroid series, and this might curtail the number of stem cells available for granulopoiesis. Under these conditions metamyelocytes might be stimulated to divide to help maintain the granulocyte population. However, proliferation appears to be a property of normal metamyelocytes since we have seen synthesis of DNA in metamyelocytes of normal bone marrow.

It seems reasonable to postulate that mitosis might still occur in some metamyelocytes since these cells are intermediate in differentiation between the proliferative myelocytes and the non-proliferative stab granulocyte. Moreover, in stage of differentiation the metamyelocyte appears to be comparable with the polychromatic erythroblast, and it is generally agreed that this cell can divide. We do not claim that all metamyelocytes are able to divide, and, at the present, we have no information on the proportion which do so.

GENETICS

Deoxyribonucleic Acid and the Ancestry of Wheat

Rees[1] has suggested that data relating to the DNA content of nuclei may provide a further clue regarding the parental composition of allopolyploid plants like *durum* and bread wheats. From Rees's results[1] it is clear that *Aegilops speltoides* is more likely to be the donor of the *B* genome of tetraploid wheat than the other members of the *Sitopsis* section of *Aegilops*. With the view of understanding: (*a*) the relationship between somatic chromosome length and DNA content; (*b*) the extent of variation in DNA content of different varieties and species of *Triticum* and *Aegilops*, we estimated the DNA content of mitotic prophase nuclei using a microspectrophotometer constructed on the two wave-length principle of Ornstein[2] and Patau[3]. We preferred prophase nuclei to interphase nuclei since inter-slide differences were less in the former. When prophase nuclei were used in measurements, we did not find chromatin diminution to the extent inferred earlier[4]. Examination of chromosome-length and DNA content indicated a definite relationship between the two[4,5]. The DNA values of *Triticum* and *Aegilops* species (Table 1), however, did not lend themselves to interpretations such as those which Rees[1] could draw.

While Rees[1] found the DNA content of *A. speltoides* to be significantly lower than that of *A. bicornis* and *A. longissima*, our results reveal no appreciable difference. Among tetraploid species Rees[1] used only *T. durum*, and if the differences in DNA values recorded by us between the more primitive *T. dicoccoides* and *T. dicoccum* on one hand and the free-threshing *T. durum* on the other are confirmed, the types of extrapolation as carried out by Rees[1] may become difficult since the parental species

Table 1. MEAN DNA CONTENT (IN ARBITRARY UNITS) OF 4c NUCLEI IN SPECIES OF *Triticum* AND *Aegilops*

Species	2*n*	No. of measurements	Mean DNA content in arbitrary units ± *S.E.*	Coefficient of variance
T. monococcum strain 1	14	115	28·06 ± 0·36	13·8
T. monococcum strain 2	14	51	26·89 ± 0·54	14·3
T. aegilopoides	14	73	27·73 ± 0·47	14·5
T. dicoccoides	28	76	53·18 ± 0·84	13·8
T. dicoccum	28	84	54·39 ± 0·82	13·8
T. durum	28	100	59·36 ± 0·85	14·3
T. aestivum var. Chinese Spring	42	108	75·39 ± 1·03	14·2
T. aestivum var. *C*-591	42	102	71·15 ± 0·60	8·5
Ae. speltoides var. *ligustica* strain 1	14	25	29·46 ± 0·89	15·1
Ae. speltoides var. *ligustica* strain 2	14	90	29·43 ± 0·48	15·5
Ae. bicornis	14	71	30·16 ± 0·59	16·5
Ae. longissima	14	64	29·85 ± 0·62	16·6
Ae. squarrosa	14	54	25·09 ± 0·45	13·2

involved would have to vary in the different tetraploids. The two varieties of *T. monococcum* and *T. aestivum* examined also showed a difference. The coefficient of variance values are rather high in our investigations, as well as those of Rees[1], and a higher order of precision in measurement will enable the use of the mean values with greater confidence. While the DNA content of nuclei would undoubtedly provide additional information of great value in tracing the phylogeny of hybrids and polyploids, an extensive survey of the extent of variability in DNA content occurring within a group of related species would have to precede the use of DNA values for such a purpose. The presence of heterochromatic segments may also influence DNA values[6,7], although in *Triticum* this may not be a complicating factor[4,5].

Effects of *n*-Butyl Methanesulphonate and Related Mutagens on Barley

MANY types of alkylating mutagens had been applied to barley before the mutagenicity of sulphonates was observed. Ethyl methanesulphonate (EMS) was the first tested and is now widely used in mutation research. The related compounds methyl methanesulphonate (MMS) (refs. 1, 3, 4), *n*-propyl methanesulphonate (*n*PMS) (refs. 1–3), isopropyl methanesulphonate (isoPMS) (ref. 3) and others also have been shown to be mutagenic on barley.

This communication presents preliminary results of the effects of alkyl sulphonates not previously reported. These agents are *n*-butyl methanesulphonate (*n*BMS) and isobutyl methanesulphonate (isoBMS). Results of treatments with MMS, *n*PMS, and isoPMS are included and compared with those obtained recently with EMS, in order to evaluate the influence of the different alkylating groups on these compounds. The biological responses induced by these chemical mutagens are compared with those obtained by X-radiation.

The sulphonates used, except MMS which was acquired from Eastman Organic Chemicals, were synthesized and tested for purity in the laboratory of the Department of Agricultural Chemistry at this University.

Seeds of hull-less Himalaya barley were stored in desiccators over saturated salt solutions for 2–4 weeks to obtain a moisture content of 14 per cent. The chemicals were applied by immersion of the barley seeds in aqueous solutions buffered at *p*H 7 with 0·2 M *tris* (2-amino-2-(hydroxymethyl)-1,3-propanediol) at 20° C for times according to treatment design. The treatment solutions of isoPMS only were changed every 50 min because this compound hydrolysed much faster than the others. After the chemical treatment the seeds were soaked in distilled water for 5 h at 20° C to reduce delayed action of the mutagens.

The biological responses of barley seeds to the various agents were measured by the percentage of seedling growth of treated versus control plants, the rate of survival (plants with germinating M_2 seedlings relative to the number of M_1 seeds planted), and the fertility, estimated from the average number of M_2 seedlings per M_1 spike. Chromosome aberrations were scored in 200 mitotic cells of shoot-tips of germinating M_1 seeds and 100 microsporocytes of field-grown M_1 plants from each treatment. The frequency of mutations was estimated from the number of chlorophyll-deficient mutations in M_2 seedling progenies.

The results (Table 1) show that all the sulphonates examined induce chlorophyll-deficient mutations. In all cases, the mutations were induced by treatments that produced low rates of damage to seedling growth and plant survival and to chromosome structure. The new chemical mutagen, *n*BMS, appears to be about as efficient as the related ethylating compound EMS, particularly since higher doses than those investigated can be applied (Froese-Gertzen, unpublished results).

Data for isoBMS were not listed in Table 1 since a treatment with 0·02 M concentration for 32 h at 20° C was not sufficient to induce either noticeable damage to seedling growth and survival rate or an appreciable number of genetic changes. However, subsequent investigations of the chemical reactivity of this compound revealed that the hydrolysis rate of isoBMS is only 1/6 that of *n*BMS. It is expected that a treatment adjusted to the slow reactivity will induce an increased mutation rate.

Treatments of barley seeds with *n*PMS were reported earlier by Ehrenberg, who obtained chlorophyll-deficient mutations in 26 per cent (ref. 1) and 12 per cent (ref. 2) of the spikes analysed. The conditions for these treatments were not described. In the experiments with *n*PMS reported by Heslot and Ferrary[3] a higher concentration than 0·02 M was used for a soaking time comparable to 30 h at 20° C, inducing mutations in 8·3 per cent of the spikes. The

Based on four replications with 200 seeds each.

mutation frequency of 13 per cent per M_1 spikes obtained in our studies does not appear to represent the optimum mutagenic efficiency of this compound since the treatments applied had little effect on seedling growth and survival

The mutation frequency of 5 per cent per M_1 spikes reported here for MMS is low in comparison with the results of Minocha and Arnason[5] (32 5 per cent), Ehrenberg[1] (16 per cent), and Heslot and Ferrary[3] (7 8 per cent) However, it seems possible that higher doses may increase the mutation rate to a level comparable with that reported by other investigators The concentration used by Minocha and Arnason was ten times higher than that in the experiments of Heslot and Ferrary[3] and the work recorded here However, it is difficult to understand that a treatment time for 2 h at 20° C (used by Minocha and Arnason[5]) was sufficient for diffusion of the mutagen solution into the seeds and for the induction of 32 5 per cent mutations, unless most of the mutations were caused by delayed action of the mutagen MMS as well as other methylating sulphonates used in recent investigations on barley appear to be more toxic, that is, methylating compounds cause more physiological damage and death at similar doses than other sulphonates, so that 1/10 of the concentration had to be used (Froese-Gertzen, unpublished results)

The exploration of isoPMS as a mutagen for barley was initiated by determining its chemical reactivity The first order hydrolysis rate constant (6 4 × 10^{-3}/min at 20° C) was similar to that of diethyl sulphate (3 45 × 10^{-3}/min at 20° C) (ref 4), and similar treatment conditions were developed Accordingly, the 0 0063 M isoPMS solution was renewed every 50 min after 30 per cent of hydrolysis had occurred Thus, these treatments cannot be compared with those of Heslot and Ferrary in which 0 055 M solutions were applied without renewal for 24 h at 24° C and in which 10 per cent mutated M_1 spikes were obtained The higher mutation rate of 20 per cent observed for isoPMS in our experiments is probably due to the fact that a higher concentration of mutagenically active agent was available when the solution penetrated into the germinal tissue.

EMS has repeatedly been reported to be a 'good mutagen' on barley Some recent results obtained with EMS are cited here for comparison with the other sulphonates This comparison shows that *n*BMS, *n*PMS and isoPMS especially merit further investigation

Data obtained from barley seeds (14 per cent moisture content) exposed to 30 kr of X-rays at room temperature show that the induction of mutation in 8 per cent of the spikes is associated with chromosome aberrations of 53 bridges and 309 fragments per 100 cells This level of injury to chromosome structure, as well as to seedling growth and plant survival in relation to the amount of induced mutation, demonstrates the lower mutagenic efficiency of radiation compared with that of most chemical mutagens investigated here

VIROLOGY

Effect of Ether on Rabies Virus

Andrewes and Horstmann[1] grouped rabies virus as ether resistant, based on reports of other investigators[2,3] During a recent investigation in this laboratory, strains of arctic rabies virus lost 95–97 per cent of their infectivity following exposure to 20 per cent ether at 4° C for 16 h This observed reduction in infectivity and the variations in reported methods for determining the effect of ether on rabies virus led to investigations comparing the action of ether on different strains of rabies virus

Five strains of rabies virus were tested 2 arctic strains isolated from foxes from Greenland, a bat rabies virus isolated from a Mexican freetail bat, a street virus obtained from a naturally infected cat, and fixed virus (CVS–25) A 20 per cent infected brain suspension prepared with 10 per cent egg-yolk diluent was mixed with anæsthetic ethyl ether (20 per cent by volume) and incubated at 4° C for 16 h Ether was removed by evaporation in an open Petri dish Control specimens without ether were tested simultaneously Serial ten-fold dilutions were prepared, and 0 03 ml of each dilution was inoculated intracerebrally into five 3-week-old mice

Table 1 EFFECT OF 20 PER CENT ETHER ON DIFFERENT STRAINS OF RABIES VIRUS AT 4° C FOR 16 H

Virus strain	Titre (MLD_{50})		Reduction in infectivity

5 0	3 49	3 49
10 0	1 49	2 88
20 0	<1 0	2 63
Control	3 67	3 63

Results are shown in Table 1 Loss in infectivity varied from 93 2 to 99 0 per cent with the field strains Reduction in fixed virus infectivity was shown to be slightly greater (99 5 per cent)

In one experiment the effect of anhydrous ether on fixed virus was compared with that of anæsthetic ether, with no apparent difference

The effects of various concentrations of ether at different time-intervals and temperatures were examined with one arctic strain The results are given in Table 2 The quantitative reduction in virus infectivity was shown to range from 0 18 logs (12 6 per cent) with 5 per cent ether to greater than 2 67 logs (99 8 per cent) with 20 per cent ether at 37° C for 2 h

Andrewes[4] has also recently demonstrated fixed rabies virus to be ether sensitive

The property of ether sensitivity supports the recent suggestion that rabies virus may be related to the myxovirus group[5,6]

Cultivation of Horsesickness Virus in Tissue Culture

Nieschulz[1] and Alexander[2] independently showed that horsesickness virus multiplies in the brains of Swiss albino mice. Alexander[3] reported later the successful cultivation of mouse-adapted horsesickness virus in the brains of guinea pigs, rats and other rodents. He also succeeded in cultivating a mouse-adapted strain of virus in embryonated hen's eggs, in which multiplication of the virus occurred in the brain of the embryo without producing any specific mortality[4]. McIntosh[5] propagated viscerotropic horsesickness virus strains in 8-day-old embryonated hen's eggs at an optimum temperature of 32° C. Embryo mortality occurred regularly during the initial passages.

This communication describes the successful propagation of horsesickness virus in tissue culture. The third mouse brain passage of a type 3 virus strain (designated as 13/63), with a mouse LD_{50} titre of $10^{-6·0}$, was selected. After removal of the nutrient medium, roller tubes containing monolayers of chicken embryo fibroblasts were each seeded with 0·2 ml. of a 1 per cent suspension of the mouse brain antigen in Hanks's balanced salt solution. The inoculated tubes were rolled at 37° C for 30 min and the monolayers were then washed. Finally, each tube received 1·0 ml. of medium consisting of Hanks's balanced salt solution containing 0·5 per cent lactalbumen hydrolysate, 10 per cent bovine amniotic fluid and 2 per cent bovine serum. The tubes were kept in roller drums at 37° C and were examined daily under low magnification. No cytopathic effects were observed.

At daily intervals the supernatant fluid plus macerated cells of two tubes, selected at random, were titrated in day-old mice by intracerebral inoculation of decimal dilutions. The virus titres were calculated by the method of Reed and Muench[6] and expressed as the negative logarithm of the dilution end-points. Table 1 represents the virus titres of the first three serial passages in chicken embryo fibroblasts.

Table 1

T C passage	Mouse LD_{50} of tissue culture material on days after seeding							
	1	2	3	4	5	6	7	8
1st	4·0	4·0	3·5	3·7	3·0	2·9	2·5	4·0*
2nd	—	—	1·0	1·0	1·5*			
3rd	0	4·0	4·0	4·0	4·0	5·0*		

* Material used for passage

The specificity of the mortality in mice was controlled by a complement fixation test[7] on the brains of mice sick after inoculation with material from the third and fifth tissue culture passages.

With the sixth passage the growth curve of the virus in tissue culture was determined. For this purpose a monolayer of chicken embryo fibroblasts in a 100-ml. medicine flat bottle was used. The culture was seeded as described before using 1·0 ml. of the fifth tissue culture passage of virus (titre $10^{-4·0}$ mouse LD_{50} per 0·03 ml.) as seed material. After adsorption, the monolayer was washed, 10 ml. of medium was added and the bottle incubated at 37° C. Aliquots of 1·0 ml. of supernatant fluid were removed daily from the bottle and titrated in day-old mice. One ml. of fresh medium was used to replace the sample removed.

In a parallel experiment a number of roller tubes were also seeded with virus as before and four tubes were collected daily. The supernatant fluids from each group of four tubes were collected, pooled and centrifuged to remove cellular material. The monolayers were washed three times with Hanks's balanced salt solution and then macerated in a volume of medium corresponding to the volume of supernatant fluid removed. Each sample of supernatant fluid and cells were titrated separately in mice. The results are summarized in Table 2.

Table 2

Culture	Mouse LD_{50} of T C material on days after seeding					
	1	2	3	4	5	6
Bottle-100 ml. flat	0	2·5	3·8	4·2	3·7	3·9
Tubes (*a*) Cells	0	2·5	3·8	4·8	4·1	4·5
(*b*) Supernatant fluid	0	1·2	3·7	4·0	3·8	4·2

Although no specific cytopathic changes were noticed during six serial passages of the virus, it is quite evident from Tables 1 and 2 that monolayers of chicken embryo fibroblasts supported the growth of horsesickness virus under the conditions described. An appreciable amount of virus appeared to be cell bound.

By using the foregoing method, a type 4 horsesickness virus strain (designated as 32/62) in its second mouse brain passage has also been adapted to multiply in chicken embryo tissue culture, and work is now in progress to adapt strains of the remaining seven types of horsesickness virus and to determine optimal conditions of growth with special reference to cell type, *p*H and temperature of incubation.

I thank Dr. K. E. Weiss, head of the Virology Section of this Institute, for advice.

STATISTICS

Generalized Inverse of a Singular Matrix

In a recent communication[1] a technique for obtaining a generalized inverse of a singular matrix $X = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$, where the square sub-matrices A and D are non-singular, has been given. The g-inverse is derived in two steps, the first involving the calculation of an approximation, and the second its correction.

Dr. M. Zelen (private communication) has pointed out that in the expressions for the sub-matrices, corresponding to those of X, which correct the approximate g-inverse, two sub-matrices $(BD^{-1}C-A)$ and $(CA^{-1}B-D)$, which are both singular, are involved. That they are singular can be proved as follows.

Let (γ, δ) be a row vector such that the constituent vectors γ and δ are non-zero, and their lengths are equal to the number of rows in A and D respectively. Then since X is singular

$$(\gamma, \delta) \begin{bmatrix} A & B \\ C & D \end{bmatrix} = 0 \qquad (1)$$

where 0 is a null vector of the same length as (γ, δ). Equation (1) yields the conditions $\gamma(BD^{-1}C-A) = 0 = \delta(CA^{-1}B-D)$, and since γ and δ are non-zero vectors, $(BD^{-1}C-A)$ and $(CA^{-1}B-D)$ must be singular.

However, despite this circumstance, the approximate g-inverse can still be corrected by using in the expressions for the correction matrix (already given by me) the approximate g-inverses of these singular sub-matrices.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, November 18

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S W 7), at 5 p.m.—Symposium on "Denudation in Limestone Regions"

UNIVERSITY COLLEGE, LONDON (in the Physiology Theatre, Gower Street, London, W C 1), at 5 p m —Dr M H Richmond "Biological Activity of Structural Analogues" (Further lecture on November 25)*

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W C 2), at 5 30 p m —Mr G B Townsend "The Colour Performance of the Secam Colour Television System"

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S W 1), at 5 30 p m —Mr F P W Winteringham "Insect Cross-resistance Phenomena Their Practical and Fundamental Implications".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 6 p m.—Mr Hulme Chadwick "One Man's Colour" (First of three Cantor Lectures on "Colour in Modern Life")

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W C 2), at 6 30 p m —Mr M. T. Hills "Electronic Telephone Exchanges"

Tuesday, November 19

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (joint meeting with the INDUSTRIAL WATER AND EFFLUENTS GROUP, at 14 Belgrave Square, London, S W 1), at 10 30 a m —Meeting on "Agricultural Effluents"

UNIVERSITY OF LONDON (at Imperial College, London, S W 7), at 1 30 p m —Mr D E Broadbent "The Input—How We See and Hear" (Third of five lectures on "The Basis of Experimental Psychology")*

UNIVERSITY OF LONDON (at the Royal Institution, Albemarle Street, London, W 1), at 5 p m —Prof Jacques Monod (Institut Pasteur, Paris) "Controlling Elements and Regulatory Circuits in Cellular Metabolism and Growth" *

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S W 1), at 5 30 p m —Mr Harold Scrutton and Mr B J O'C Donelan "Some Features of the Civil Engineering Work in Cammell Laird's Shipyard".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W C 2), at 5 30 p m —Prof F C Williams, F R S , Dr J F Eastham and Mr L S Piggott "Analysis and Design of Pole Change Motors using Phase-Mixing Techniques", Mr C St J Lamb "Commutatorless Alternating Voltage-Fed Variable-Speed Motor"

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "A New Approach to Teaching Reliability" opened by Mr R C Winton

UNIVERSITY OF LONDON (at Imperial College, London, S W 7), at 5 30 p m —Prof A R Hall "The Historical Relations of Science and Technology" (Inaugural Lecture)

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr R P Michael "Neurological Mechanisms and the Control of Sexual Behaviour" (Tenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMATIC CONTROL GROUP (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "Is Machine Development Outstripping Man's Capabilities ?"

PLASTICS INSTITUTE, LONDON SECTION—ENGINEERING SUB-GROUP (at the Wellcome Building, Euston Road, London, N W 1), at 6 30 p m —Mr. J R Baines and Mr P M George "Developments in Extrusion Techniques for Unplasticized P V C "

Tuesday, November 19—Wednesday, November 20

INSTITUTION OF GAS ENGINEERS (at Church House, Westminster, London, S W 1), at 9 30 a m daily—29th Autumn Research Meeting

Wednesday, November 20

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W 12), at 2 p m —Dr P Walker "Biochemical Procedures in the Differential Diagnosis of Metabolic Bone Disease" *

PLASTICS INSTITUTE (at Brunel College, Woodlands Avenue, Acton, London, W 3), at 2 30 p m —Dr C L Child "Some Factors Affecting Products Design" (Students' Lecture)

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 2 30 p m —Mr D I Lawson "Research into Fire Protection"

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W 1), at 5 p m —Dr M H P Bott "Gravity Measurements on the North-East Part of the Irish Sea", Mr C S Hutchison "A Gabbro-Granodiorite Association in Singapore Island" (to be read by Prof J Sutton).

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 15 p m —Dr D J Newell "Statistical Aspects of the Demand for Maternity Beds"

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W 1), at 5 30 p m —Mr M J Van der Zijden and Mr S R Hills "Control of Gasoline Quality in Relation to Inlet System Deposits"

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (joint meeting with the SCIENCE AND GENERAL DIVISION, at Savoy Place, London, W C 2), at 5 30 p m —Dr D N Truscott "Computers in Control of Processes—the Coming Revolution in Industry".

SOCIETY OF APOTHECARIES OF LONDON, FACULTY OF THE HISTORY OF MEDICINE AND PHARMACY (at Apothecaries' Hall, Blackfriars Lane, London, E C 4), at 5 30 p m —Prof Alan Kekwick "The Soho Cholera Epidemic, 1854".

BRITISH INSTITUTION OF RADIO ENGINEERS, EDUCATION GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 p m —Mr R A T Howell, Group Captain J H Stevens, Mr W K Newson and Mr H Arthur "Systematic Selection Procedures for Technical Courses".

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Prof J Z Young, F R S 'Measuring and Computation by Brains and Machines" (Thomas Hawksley Lecture)

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the SOUTH-WEST ESSEX TECHNICAL COLLEGE CHEMICAL SOCIETY, at the South-West Essex Technical College, Forest Road, Walthamstow), at 7 p m —Dr P N Campbell "The Biosynthesis of Proteins"

Thursday, November 21

REINFORCED CONCRETE ASSOCIATION (joint meeting with the SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP, at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S W.1), at 2 30 p m —Meeting on "Lightweight Aggregates"

ASLIB (at 3 Belgrave Square, London, S W 1), at 5 p m —Mr S B Page "The Production of Library Publications"

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 p m —Dr C W Nutt and Dr K Bromley "Conditions for the Flotation of Beryl", Mr R. Greenberg "Structure-Gold Relationships as Revealed by some Witwatersrand Mine Survey Plans"

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W 1), at 5 p m —Dr Léon Croizat "Problems of Panbiogeography"

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W 1), at 5 p m —Annual General Meeting Dr M L Cartwright "From Non-linear Oscillations to Topological Dynamics" (Presidential Address)

INSTITUTION OF CIVIL ENGINEERS, TRAFFIC ENGINEERING GROUP (at Great George Street, Westminster, London, S W 1), at 5 30 p m —Informal Discussion on "Integration of Motorways in Urban Areas" introduced by Dr T E H Williams.

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m.—Dr M Shepherd "Epidemiology and Mental Disorder" (Eleventh of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W 1), at 6 p m —Scientific Papers

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S E 1), at 6 p m —Informal Discussion on "Pneumatic v Electronic Controls"

OCCAM SOCIETY (at the Northampton College of Advanced Technology, St John Street, London, E C 1), at 6 15 p m —Discussion on "The 5000 Year Leap (Technology, Social Science and the Underdeveloped Countries)" opened by Dr E T Sherwood

INSTITUTION OF MECHANICAL ENGINEERS, GRADUATES' AND STUDENTS' SECTION (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 30 p m —Mr P Irving "Modern Trends in Two-stroke Petrol Engine Design"

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 7 30 p m —Laboratory Meeting

Thursday, November 21—Saturday, November 23

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W 1), at 10 30 a m daily—Discussion Meeting on "The Physical and Chemical Basis of Muscular Contraction" organized by Prof A F Huxley, F R S , and Dr H E Huxley, F R S

Friday, November 22

INSTITUTION OF MECHANICAL ENGINEERS, INTERNAL COMBUSTION ENGINE GROUP (at 1 Birdcage Walk, Westminster, London, S W 1), at 7 p m —Mr L S Snell "The Design and Evolution of an Aircraft Rocket Engine".

Friday, November 22—Saturday, November 23

BRITISH SOCIETY FOR IMMUNOLOGY (at the Wellcome Building, 183 Euston Road, London, N W 1), at 10 a m daily—Autumn Meeting Prof. Astrid Fagraeus (Sweden) "Mixed Hæmadsorption—a New Antibody Tracing Technique and some of its Applications" (Prausnitz-Giles Lecture)

Saturday, November 23

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Dr Bengt Danielsson "The Islands of the South Seas in the Modern World".*

Monday, November 25

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W C 2), at 2 30 p m and 5 30 p m —Colloquium on "Recent Advances in D C Amplifiers"

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W 12), at 4 p m —Prof A W Woodruff "Recent Advances in Tropical Medicine" *

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Is Load Shedding Necessary and How Can Its Effects be Minimized ?" opened by Mr A E Hawkins

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 5 30 p m —Dr E Schatzman (Paris) "Nuclear Reactions at the Surface of Stars and Stellar Evolution" *

BRITISH MEDICAL ASSOCIATION (at the National Hospital for Nervous Diseases, Queen Square, London, W C 1), at 6 p m —Dr Macdonald Critchley, F R C P "The Problem of Visual Agnosia" (Twelfth Victor Horsley Memorial Lecture) *

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 6 p m —Dr. T Vickerstaff "Scientific Aspects" (Second of three Cantor Lectures on "Colour in Modern Life")

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

GRADE B LECTURER (with an honours degree) IN MATHEMATICS IN THE DEPARTMENT OF MATHEMATICS AND PHYSICS—The Director of Education, The Polytechnic, 309 Regent Street, London, W 1 (November 22)

LECTURER (medical or non-medical graduate) IN ANATOMY—The Secretary, Institute of Ophthalmology (University of London), Judd Street, London, W C 1 (November 23)

LECTURER (Grade II) IN PSYCHOLOGY—The Registrar, The University, Bristol (November 25)

LECTURER or ASSISTANT LECTURER AT THE TIDAL INSTITUTE AND OBSERVATORY—The Registrar, The University, Liverpool, quoting Ref CV/422 (November 25)

JUNIOR LECTURER, LECTURER or SENIOR LECTURER IN PHYSICS at Massey University College of Manawatu, Palmerston North, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, November 29)

BIOCHEMIST (with an honours degree in biochemistry or equivalent) IN THE DEPARTMENT OF STEROID BIOCHEMISTRY, to study the biosynthesis and metabolism of androgenic steroids—The Secretary of University Court, The University, Glasgow (November 30)

LECTURER (graduate in science with qualifications in botany or agricultural botany, and preferably with training in crop or plant physiology) IN BOTANY—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C 2 (November 30)

SENIOR DEMONSTRATORS (2) (with a science degree with physics as a major subject, preferably with honours, and some teaching experience) IN PHYSICS at the University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (London and Brisbane, November 30)

CHAIR OF ZOOLOGY at the University of Malaya—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (London and Kuala Lumpur, December 7)

LECTURER IN ORGANIC CHEMISTRY at QUEEN'S COLLEGE, Dundee—The Secretary, University of St Andrews, Queen's College, Dundee (December 7)

LECTURER (with special interest in one or more of the following fields soils, conservation or geomorphology) IN GEOGRAPHY—The Secretary, University College, Gower Street, London, W C 1 (December 7)

ASSISTANT KEEPER (Grade I or Grade II) IN THE DEPARTMENT OF ZOOLOGY—The Secretary, National Museum of Wales, Cardiff (December 10)

CHAIR OF BIOLOGY (with special reference to ecology)—The Secretary, University of Lancaster, Bailrigg House, Lancaster (December 14)

SENIOR LECTURER IN PHYSICAL CHEMISTRY at the University of Western Australia—The Registrar, University of Western Australia, Nedlands, Western Australia, or The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, December 14)

CHAIR OF PHYSIOLOGY at St Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W C 1 (December 17)

LECTURER IN GEOCHRONOLOGY AND ISOTOPE GEOLOGY IN THE DEPARTMENT OF GEOLOGY—The Registrar The University, Leeds 2 (January 1)

MASTER TO TEACH BOTANY to Scholarship level (any other science subject, particularly chemistry, would be welcome)—The Headmaster, Blundell's School, Tiverton, Devon

POST-DOCTORAL RESEARCH ASSISTANT, for work in the field of colour centres in the alkali halides—Dr P W M Jacobs, Department of Chemistry, Imperial College, London, S W 7

RESEARCH STUDENT (with a good honours degree) IN THE DEPARTMENT OF HUMAN BIOLOGY AND ANATOMY, for developing methods of fixation and embedding for electron microscopy—Prof R Barer, The University, Sheffield

RESPIRATORY PHYSIOLOGIST, for work mainly in the wide-open field of high-pressure physiology—The Superintendent, Royal Naval Physiological Laboratory, Alverstoke, Hants

TECHNICIAN or STUDENT TECHNICIAN FOR THE BIOLOGY DEPARTMENT—The Secretary, Royal Free Hospital Medical School, 8 Hunter Street, London, W C 1

Pedigree

The "Mistral 6L" is developed from the MSE "Major Refrigerator" Centrifuge—famous throughout the world for its dependability and performance.

The New MSE "MISTRAL 6L"
General Purpose Refrigerator Centrifuge

The MSE "MISTRAL 6L" represents an outstanding advance in design and performance of large capacity refrigerator centrifuges. It incorporates the following new features of great practical importance to the user:

- 4x1250 ml and 6x1000 ml Swing-out Heads up to 2,500 r.p.m.
- Wide range of other Swing-out and Angle Heads for large numbers of smaller bottles and tubes at high speeds.
- Exceptionally fast acceleration to top speeds
- Electronic speed pre-selection and control.
- New type of drive mounting giving vibration-free running, even with some imbalance
- Compact and space saving—33″ (84 cm) wide, 33″ (84 cm) front to back.
- Stainless steel bowl and working-top lid.

For full details please write to:

APPOINTMENTS VACANT

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Lecturer in Physics in the Department of Physics in the Faculty of Science The research interests of applicants should lie in the field of organic Molecular physics, in which the Department has an active programme Duties to commence as soon as possible Salary scale £1,250 to £2,150 per annum, initial salary according to qualifications and experience Membership of F S S U and children's allowance scheme Applications should be sent not later than December 1, 1963, to the Registrar, The University, Manchester, 13 from whom further particulars and forms of application may be obtained

Applications, by air mail letter in the first instance, will be received from overseas candidates, who should state the names and addresses of at least three persons to whom reference can be made

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

Assistant Experimental Officer required for a programme of research on the biochemistry of lipids and their possible significance in cardiovascular degeneration in experimental animals The officer will be required to assist with techniques such as gas chromatography and radio-gas chromatography Qualifications pass degree or H N C or, if under 22, G C E "A" level (preferably in chemistry and zoology), O N C, or equivalent Starting salary £490 (age 18) to £858 (age 26), scale maximum £1,053 Pension scheme

Application forms from Secretary, N I R D, Shinfield, near Reading, quoting ref 63/N/13

SCIENTIFIC FELLOWSHIPS IN EUROPE

The CIBA Fellowship Trust (which was founded by the CIBA Companies of Great Britain for the purpose of improving and increasing the interchange of ideas between scientists in the United Kingdom and on the Continent) will award a number of CIBA Fellowships to enable graduates of Universities of the U K, Northern Ireland and Eire (who may be at present either at a University or in industry) to carry out research at Continental Universities in chemistry, physics or some other allied scientific subject These Fellowships (of a basic value of £600 for pre-doctoral and £900 for post-doctoral Fellows, plus appropriate additional allowances depending on place of study, etc) will be tenable for at least one year, with the possibility of renewal for a further one or two years, and will be awarded in April, 1964

Those interested should write to the Secretary of the CIBA Fellowship Trust, CIBA United Kingdom Limited, 96 Piccadilly, London, W 1, who will provide full details and application forms The closing date for applications is January 15, 1964

COMMONWEALTH AGRICULTURAL Bureaux Applications are invited for the post of Scientific Information Officer at the Commonwealth Bureau of Plant Breeding and Genetics, Cambridge Work includes the abstracting and reviewing of biological literature Applicants should possess a botanical or agricultural degree, the ability to write correct English and preferably a knowledge of one or more foreign languages Salary £791 to £2,061 Starting salary according to age, qualifications and experience Increments up to two years granted for completed years of compulsory National Service and two further increments after two years' satisfactory service for applicants aged 32 or under at date of appointment Provision for superannuation —Applications, stating age, qualifications and other particulars and names of referees (work and character), should be submitted by December 31, 1963, to the Director of the Bureau, School of Agriculture, Cambridge

Scientific Civil Service

SCS

SCIENTISTS IN GOVERNMENT SERVICE

The following are examples of existing vacancies, which may be filled at SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER level

CHEMICAL INSPECTORATE, Woolwich, London—Chemists with interest or experience in analytical chemistry including MODERN INSTRUMENTAL METHODS

EXPLOSIVES RESEARCH AND DEVELOPMENT ESTABLISHMENT, Waltham Abbey, Essex—Chemical Engineer to lead a small team in the study of conveying and metering FLOWS OF MATERIALS, particularly solids, the mixing of PASTES AND POWDERS, the growth of CRYSTALS and the design of FURNACES for special purposes (Senior Scientific Officer only)

POST OFFICE RESEARCH STATION, Dollis Hill, London—For fundamental work on the detection and measurement of weak electromagnetic signals for several fascinating applications (including SATELLITE COMMUNICATIONS) at low and room temperatures in the frequency range from near zero to 10 gigacycles per second

FISHERIES EXPERIMENT STATION, Conway—Biologist to develop culture methods for MOLLUSCA and CRUSTACEA, with special responsibility for hatchery rearing of prawns and other crustacea

GOVERNMENT COMMUNICATIONS HEADQUARTERS, Cheltenham, Glos—Mathematicians for computer application and programming and for COMBINATORIAL AND STATISTICAL RESEARCH

There are many other vacancies in most scientific disciplines Recruitment by the Civil Service Commissioners is to permanent and pensionable posts

INQUIRIES TO Civil Service Commission, 23 Savile Row, London, W 1, stating age and qualifications

FORESTRY COMMISSION

ALICE HOLT RESEARCH STATION, Farnham, Surrey

ASSISTANT FOREST PATHOLOGIST (male) required for research and advisory duties on Tree diseases Permanent, pensionable post graded Scientific Officer/Senior Scientific Officer QUALIFICATIONS First- or second-class honours degree in forestry or biology with experience of plant pathology and mycology

Further information about the duties is available from the Director at above address

APPLICATION FORMS from Civil Service Commission, 23 Savile Row, W 1, quoting S/52-53/AH Early application advised

D.S.I.R.

BUILDING RESEARCH STATION, Garston Watford, Herts

PHYSICIST OR ENGINEER (graded SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER) to undertake fundamental study (in parallel with field studies of wear and the development of abrasion testing machines) of processes of abrasion of brittle and visco-elastic materials under conditions of high stress and at high rates of strain

APPLICATION FORMS from Director at above address Closing date November 26, 1963

HUMBER LABORATORY, Hull, Yorkshire

ASSISTANT EXPERIMENTAL OFFICER to join small team in bacteriology section concerned mainly with estimation of quality of fresh and processed fish QUALIFICATIONS If over 22, degree, Dip Tech, or H N C in Chemistry Knowledge of bacteriological techniques required

APPLICATION FORMS from Director, Torry Research Station, Aberdeen Closing date November 26, 1963

ROYAL NAVAL SCIENTIFIC SERVICE

SENIOR SCIENTIFIC OFFICERS and SCIENTIFIC OFFICERS

(1) ADMIRALTY SURFACE WEAPONS ESTABLISHMENT, near Portsmouth

Qualifications: preferably first- or second-class honours degree in MATHEMATICS, PHYSICS or ELECTRICAL ENGINEERING for research and advanced investigations into RADIO COMMUNICATION and RADAR TECHNIQUES, assessments, computers and data handling The work is intended to lead towards future radar and radio weapons systems Experience in one or more appropriate fields expected

(2) ADMIRALTY COMPASS OBSERVATORY, Slough

Qualifications preferably first- or second-class honours degree in PHYSICS or ELECTRICAL ENGINEERING, interest in INERTIAL NAVIGATION SYSTEMS, experience in this field or in light electromechanical servo-mechanisms, digital computers or data handling, with special reference to real-time computation

EXPERIMENTAL OFFICERS and ASSISTANT EXPERIMENTAL OFFICERS

Vacancies in Portsmouth, Weymouth and West London areas for work on Radio, Radar, Computers, Data Handling, Sonar, and Inertial Navigation systems Previous experience and interest in one or more of the subjects listed is essential

APPLY to Superintendent of Scientific Personnel, Admiralty, Empress State Building, London, S W 6

MINISTRY OF AVIATION

ROYAL AIRCRAFT ESTABLISHMENT, Farnborough and Bedford

PHYSICISTS, ENGINEERS AND MATHEMATICIANS (SENIOR SCIENTIFIC OFFICERS) for research, development and design work having wide application in CIVIL AND MILITARY AVIATION and GUIDED WEAPONS

Subjects being studied include satellite design and instrumentation, guidance systems and servomechanisms, inertial navigation, magnetogasdynamics, hypersonic and supersonic aerodynamics, high-speed computing, blind landing, electronics and semi-conductors, aircraft and spacecraft structures, etc QUALIFICATIONS First- or second-class honours degree or equivalent and at least three years' postgraduate experience

WRITE for booklet and application form to Dr M J Lighthill, F R S, Director, Royal Aircraft Establishment, Farnborough, Hants

SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

SALARIES S O £791–£1309
(Increments and special £95 award for approved post-grad experience)
S S O £1438–£1772
(Starting salary may be above minimum)
Salaries are supplemented in the London Area

QUALIFICATIONS
S O : 1st or 2nd Class Hons Degree or Dip Tech in appropriate subject Age under 29
S S O. As above plus at least 3 years post-graduate research Age 26 to 31

ASST. EXPERIMENTAL OFFICER/EXPERIMENTAL OFFICER

SALARIES A E O £490 (age 18) – £691 (age 22) – £858 (age 26) – £1053.
E.O £1164–£1431
Salaries are supplemented in the London Area

QUALIFICATIONS:

Degree, Dip Tech, H N C or equivalent in appropriate subject Under age 22, minimum qualification is 2 G C.E 'A' levels in Scientific subjects. A E.O age 18–27. E O 26–30

Full details of careers in the SCIENTIFIC CIVIL SERVICE are available on request from Civil Service Commission, 23 Savile Row, W 1

Return to Research in Britain

Are you a British scientist in the U.S.A. thinking of returning to work in Britain? You may find what you are looking for, without having to go home first, in the Civil Service, the United Kingdom Atomic Energy Authority, or the Central Electricity Generating Board.

Research Fellowships and Permanent Appointments
There are openings in all branches of science. The order in which they are most numerous is (i) physics, mathematics, engineering, and metallurgy; (ii) chemistry and biochemistry; (iii) biology. The research ranges from the most fundamental to the most applied.

A selection board of scientists will be coming to Washington, New York and San Francisco from March to May, 1964. If you would like an appointment with them, would you write by 31st January, 1964, to: Dr. J. A. Saxton, Director, United Kingdom Scientific Mission, British Embassy, Washington, D.C.

**Issued jointly by the Civil Service Commission,
the U.K. Atomic Energy Authority, and the Central Electricity Generating Board**

IMPERIAL CHEMICAL INDUSTRIES LIMITED

PLASTICS DIVISION

DEVELOPMENT PROJECTS... TECHNICAL SERVICE

MEN of diverse skills required for process and application development projects covering a wide range of plastics, and for technical service posts in support of sales

QUALIFICATIONS: preferably good honours degree in chemistry, physics, or chemical engineering, or proven ability and experience Age range 23 to 33

EXAMPLE: Physicist, preferably with research degree, required to play leading role in small team studying rheology of polymer melts Work will range from laboratory studies to application on full scale extruders and moulding machines, opportunities for making fundamental advances in knowledge and for their translation into improved techniques and equipment

LOCATION: Welwyn Garden City

Apply briefly to

The Personnel Manager,
Imperial Chemical Industries Limited,
Plastics Division, Welwyn Garden City, Herts,
quoting Reference A 5100

PRODUCT DEVELOPMENT SCIENTISTS

with B.Sc. (Honours), Dip.Tech. or Grad.R.I.C.

Vacancies exist for scientists capable of Product Research and Development in the four Unilever Research Laboratories at

COLWORTH HOUSE, BEDFORDSHIRE
—for human foods and animal feedstuffs

ISLEWORTH, MIDDLESEX
—for toilet preparations

PORT SUNLIGHT, CHESHIRE
—for soaps, detergents, chemicals and adhesives

WELWYN, HERTFORDSHIRE
—for edible oils, margarine and ice-cream

Successful applicants will earn salaries of at least £900, with generous increments for post-graduate experience If you wish to contribute to research of immediate relevance to industry, please contact

STAFF OFFICER (REF RHS/IA), RESEARCH DIVISION, UNILEVER HOUSE, LONDON, E C 4

UNILEVER RESEARCH

ST GEORGE'S HOSPITAL

LINCOLN

COUNTY MEDICAL PHYSICS DEPARTMENT

Applications are invited from both young men and women for the following posts in the Medical Physics Laboratory

(a) Technician Candidates should have a good school record with passes in Physics and Mathematics at "O" level of the G C E and O N C in Applied Physics or Inter-B Sc or City and Guilds Intermediate or a qualification equivalent Salary scales £630 rising to £785 per annum

(b) Technician-in-training Candidates should have a good school record and studied for 'A" level of the G C E in Physics and Mathematics Salary according to age, between £310 per annum and £520 per annum

Further information can be obtained from the Physicist-in-charge Applications, giving full particulars of education, etc, together with the names of two referees, should be addressed to the Secretary, as soon as possible

---

UNIVERSITY OF OXFORD

UNIVERSITY LECTURESHIP IN PHYSIOLOGY

The University proposes to appoint, with effect from October 1, 1964, a University Lecturer in Physiology Some preference may be given to a candidate with interests in the general field of body fluids and electrolytes

Stipend in the scale £1,250 (under age 28) to £2,285, or, if medically qualified, £1 610 to £2,450 Children's allowances of £50 per annum for each child, and F S S U Three copies of applications, with the names of two referees, by January 31, 1964, to the Administrator, Department of Physiology, South Parks Road, Oxford, from whom further particulars can be obtained

The lectureship can be held jointly with a college Fellowship and the attention of applicants is drawn to the vacancy for a Fellow in Physiology at St Catherine's College, Oxford

---

ST CATHERINE'S COLLEGE

OXFORD

FELLOWSHIP IN PHYSIOLOGY

The College proposes to elect to an Official Tutorial Fellowship in Physiology to be held in conjunction with a University appointment The person appointed will be expected to take up his duties from October 1, 1964

Further particulars may be obtained from the Master, St Catherine's College, Oxford The attention of applicants is drawn to the advertisement for a University Lecturer in Physiology

---

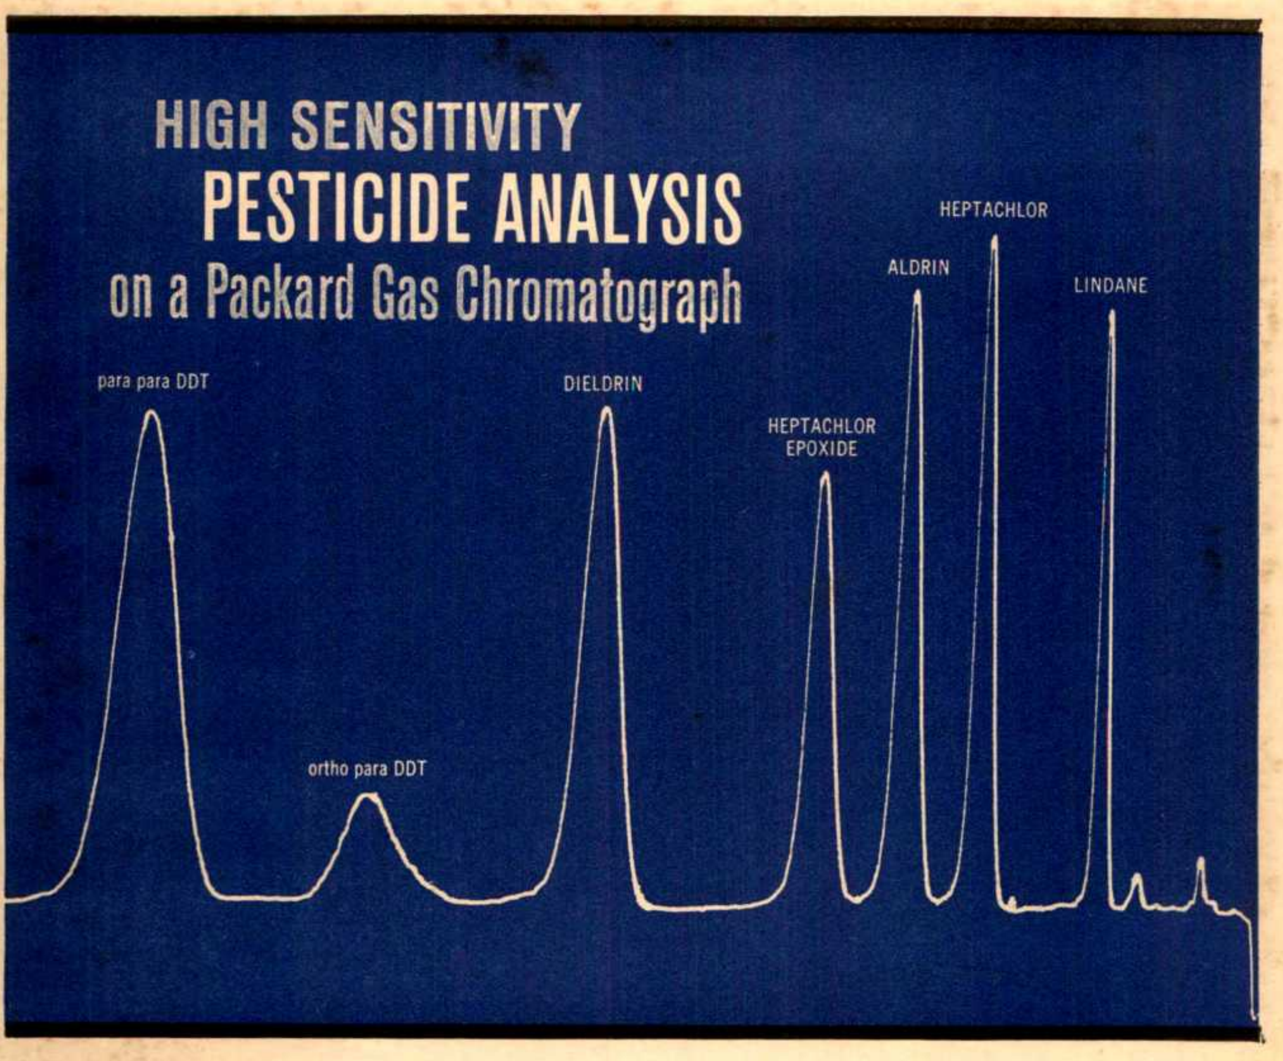
KENYA GOVERNMENT

Zoologist required by the Veterinary Department for the supervision of routine helminthological diagnosis, research on problems of helminthiases of livestock especially the bionomics of nematode and trematode infestations Candidates should possess an honours degree in zoology and research or other experience in parasitology or a higher degree in zoology is desirable Appointments on contract for two tours of two years each tour with gratuity (taxable) of 25 per cent of total emoluments on satisfactory completion Salary scale £1,266 to £2 448 a year, starting salary depending on experience, taxation at local rates Government quarters at low rental generally available, if not available a housing allowance is payable Free return passages for officer, wife and dependent children Approximately fourteen weeks home leave on full pay after each tour, annual local leave of sixteen days also granted Educational allowances at varying rates

Application should be made to Director of Recruitment, Department of Technical Co-operation, Eland House, Stag Place, London, S W 1, (Please quote RC 217/80/06 and state full name)

ROYAL VETERINARY COLLEGE (University of London) Academic Postgraduate Diploma in Animal Health Applications are invited from veterinary surgeons for a newly established post of Senior Lecturer Candidates should have had wide experience of animal health husbandry and preventive medicine and have specialized knowledge of one of these fields The successful candidate will be required to organize and develop a course of instruction for postgraduate students registered for the above Diploma Salary scale £2,025 rising by annual increments of £75 to £2,400 and then by one increment of £50 to £2,450 plus £80 London allowance Initial salary within the scale according to experience and qualifications F S S U, and children's allowance—Application forms and further particulars may be obtained from the Secretary, the Royal Veterinary College, Royal College Street, London, N W 1, and should be returned not later than December 31, 1963

HIGH SENSITIVITY
PESTICIDE ANALYSIS
on a Packard Gas Chromatograph



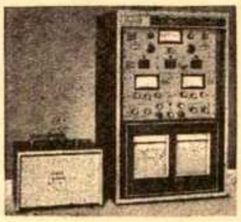
Routine determination in the parts/billion range, plus extreme versatility and speed of analysis recommend the Packard Model 7508 Gas Chromatograph to research workers in the biochemical and biomedical disciplines.

Chromatograms of pesticide analysis (above) display clearly defined peaks to indicate the instrument's high sensitivity to trace amounts. Advanced electronics embodied in the digital temperature programmer, proportional temperature control, electrometers, and high voltage supply modules extend the capability of Model 7508 to every area of gas chromatography. The Dual Column Oven which may be operated in isothermal or programmed modes, accepts any of five dual plug-in detectors. Columns and detector assemblies may be lifted out of the oven to permit changing or making connections outside heated oven area.

Your Packard Sales Engineer can provide complete details and performance criteria. Write for Bulletins and Specifications.

EXPERIMENTAL CONDITIONS:

SAMPLE—2 microliters of hexane solution containing:
Lindane .25 x 10^{-9} gm.
Heptachlor .5 x 10^{-9} gm.
Aldrin .5 x 10^{-9} gm.
Heptachlor Epoxide .5 x 10^{-9} gm.
Dieldrin .75 x 10^{-9} gm.
ortho para DDT & para para DDT 2.5 x 10^{-9} gm.



COLUMN: 5′ x ¼″ all glass
LIQUID PHASE: 10% Dow Corning Silicone Fluid (DC200)
SUBSTRATE: 60-80 mesh Chromosorb W (acid and base washed)
CARRIER GAS FLOW RATE: 120 cc Nitrogen/min.
INLET HEATER TEMP.: 225°C
COLUMN TEMP.: 190°C
DETECTOR TEMP.: 195°C
OUTLET TEMP.: 200°C
DETECTOR: Packard Electron Capture with 150 millicurie Tritium Source
ELECTROMETER RANGE: 3 x 10^{-9} amperes full scale
DETECTOR VOLTAGE: 50
NOISE LEVEL: 3 x 10^{-12} amperes
CHART SPEED: 30 inches/hour

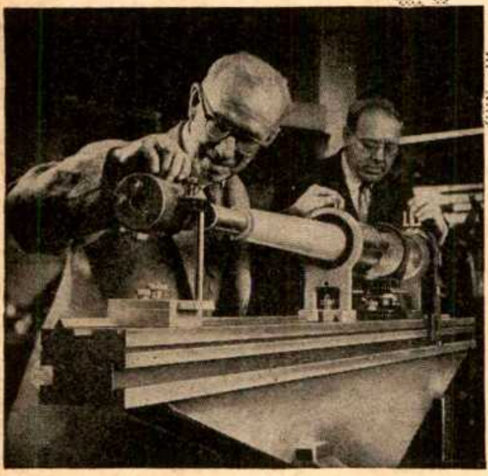
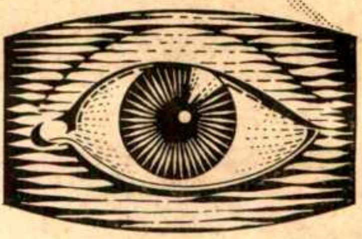
BECK *optical and scientific instruments*

a name to keep your eye on



AN EYE FOR CRAFTSMANSHIP

The discriminating eye sees too few examples of true craftsmanship these days, but a Beck instrument is always a joy to see and to use! At R. & J. Beck the traditional skills of the glass worker and instrument mechanic are co-ordinated with the latest manufacturing techniques to meet tomorrow's demands for scientific equipment of ultra-precision and super-efficiency; as typified in the photograph above showing two generations of Beck craftsmen examining the world's most advanced optical bench. For details of our comprehensive range of optical benches send for catalogue Section T.



As makers of precision optical equipment for more than a century Beck have been associated with many notable scientific developments. Our research technicians are continually working on new and improved instruments. Keep your eye on Beck!

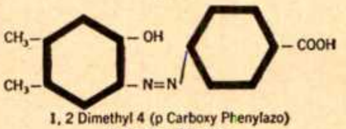
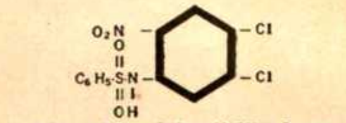
ANTI-CANCER AGENTS

CPA



1, 2 Dimethyl 4 (p Carboxy Phenylazo) 5 Hydroxy Benzene

DCBN



1,2 Dichloro 4 Benzene Sulfonamido 5 Nitro Benzene

A mixture of 1, 2 Dimethyl 4 (p carboxy phenylazo) 5 Hydroxy Benzene (CPA) and 1, 2 Dichloro 4 Benzene Sulfonamido 5 Nitro Benzene (DCBN) when fed to mice of the SPFS strain bearing spontaneous mammary cancers, cured permanently about one third of the animals.

The investigators adjudged the permanency of the cure of the cancers when the neoplasm decreased in size, disappeared and remained undetectable for at least 5 months.(1).

The maximal number of cures was obtained with 6 grams of CPA and 0.5 grams of DCBN per kilo of ration. This represents the first case of the cure of such cancers by any chemical agent.

These biochemicals were conceived on the basis of a demonstration that spontaneous cancer differed from normal host tissues in that they synthesized vitamin B_{12}.

Previously it was demonstrated that certain spontaneous mammary cancers of mice differed from normal mouse tissues in that cancer cells synthesized Vitamin B_{12} (2) (3). This metabolic difference allowed the prediction and the realization of antimetabolites poisonous to the cancers that are harmless to the host mice (4) (5).

These new anti-cancer agents, (CPA) and (DCBN) are members of a series of antimetabolites which have been shown to inhibit biosynthesis of Vitamin B_{12} in microorganisms. It was reported that these biochemicals demonstrated no detectable harmful effects on the host mice as the dosage used to bring about the desired results.

CPA and DCBN are available on 24-hour delivery basis anywhere in continental USA. Call 216-662-0212 or write Nutritional Biochemicals Corporation, 21010 Miles Avenue, Cleveland 28, Ohio.

All chemicals described are for chemical and investigational use only. They are not offered for clinical or drug use. The literature reference should not be interpreted as either an endorsement or disapproval of the biochemical by the cited investigator.

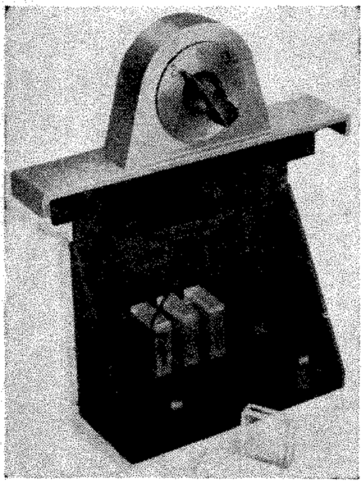
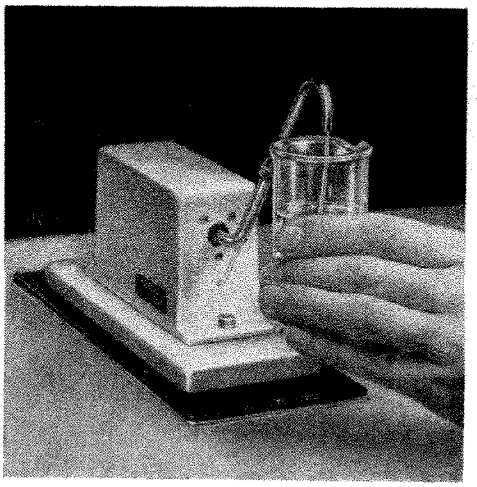
UNICAM

SP.600 with AUTOCELL

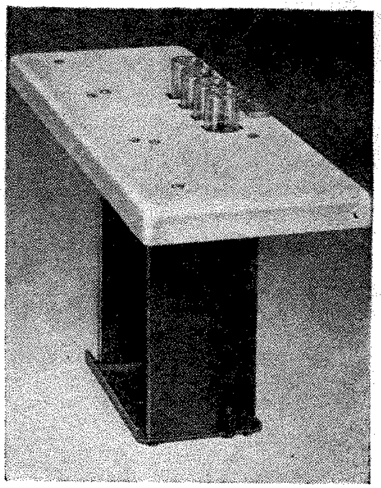
MICROCELL ACCESSORY AND TEST TUBE HOLDER



SP.680 MICROCELL ACCESSORY



SP.625 AUTOCELL



SP.630 TEST TUBE ACCESSORY

The Unicam SP.600 Visible Spectrophotometer is now available with the SP.625 Autocell Accessory; a unit which greatly reduces sample handling time. Also available is the SP.649 Power Supply Unit. This replaces the dry batteries normally supplied and provides an all-mains operation.

These latest developments, together with the SP.680 Microcell Accessory and the SP.630 Test Tube Holder, make the SP.600 Spectrophotometer the most versatile instrument for all absorption measurements in the region 360-1000 mμ.

The Autocell, Microcell and Test Tube Accessories are easily interchangeable and each is designed to fit into the cell well of the main instrument—no special fitting arrangements are necessary.

SP.625 Autocell

The new Unicam Autocell provides a completely automatic means of filling and emptying the special sample cell. One control is provided (see illustration above) and the operator can fill and empty the sample cell without any risk of cell breakage, sample spillage or contamination. This speeds analysis and greatly improves accuracy and reliability. The minimum sample volume required is 5 ml. Tests have shown that less than 1 per cent of sample volume remains after emptying. The sample comes into contact only with fine bore polythene or stainless steel tubing.

SP.649 Power Supply Unit

The Power Supply Unit has been designed to replace both H.T. dry batteries and can be easily fitted to every SP.600. It will appeal to those who require the extra convenience and reliability of an all-mains operated instrument. The unit consumes less than 5 watts and its output is unaffected by mains voltage fluctuations of +12½ per cent.

Full information on the SP.600 and its accessories will gladly be sent on request.

SCIENCE AND THE METAMORPHOSIS OF GOVERNMENT

THE background paper*, which examines the links between scientific research and economic growth and discusses the implications of those relations for the policies for science adopted by the member countries of the Organization for Economic Co-operation and Development, was prepared at the request of the Committee for Scientific Research for the Ministerial Meeting on Science in Paris during October 3–4, and covers much ground in common with the report on *Science and the Policies of Governments*†, in which the meeting of Ministers for Science was specifically recommended (see *Nature*, 200, 199, 1963) The latter report, prepared by an *ad hoc* Advisory Group on Science Policy appointed by the Secretary-General of the Organization, discusses the implications of science and technology for national and international affairs. It was, in fact, intended to stimulate the discussions at the meeting recommended on national science policy, international scientific co-operation and on the role of the Organization itself in furthering the development of scientific policies which could contribute effectively to economic growth It is concerned with outlining the factors involved, including the extent to which the development of a sufficient supply of trained manpower, including managers, effective communications and statistics and the like were contributory factors

This background paper deals more specifically with economic aspects of scientific research and seeks to display some of the directions in which further knowledge is desirable It is more detailed than the report from the Advisory Group on Science Policy, and, while it insists on the importance of scientific research as a contributory factor in economic growth and on the necessity for a sound balance between investment in real capital and investment in the advancement of knowledge, it is careful not to claim too much Readers will be struck by the extent to which the argument follows that developed in two successive presidential addresses to the British Association for the Advancement of Science. investment in science and investment in man (see *Nature*, 195, 875, 1962, 199, 877, 1963) They will also note the admission that it is still impossible to estimate with any precision the return on investment in research and development, in the form of increased output The evidence is there of a connexion, but all the factors of economic growth are intimately interrelated, and while the paper is concerned primarily with the contribution from the advance of knowledge it does not neglect other aspects It points out, moreover, that the available stock of knowledge does set a limit on economic growth, particularly in countries which are already using the most advanced techniques, and also that there are grounds for believing that, in a market economy, the allocation of resources to the advance and spread of knowledge tends to be below the level required for the most efficient long-term growth of the economic system as a whole Further, there are social and welfare benefits from the advance of knowledge which may affect economic growth indirectly, and formulation of a national research policy should take into account such non-economic objectives as well as economic ones

While investment in capital equipment may be regarded as one immediate cause of the increase in productivity, that increase depends largely on the new technology built into new capital equipment, and this technology in turn is the result of research, invention and development, springing in their turn largely from education in the widest sense of the word Attempts made to measure the contribution to economic growth of changes in the input of the principal factors of production usually suggest that in mature industrial countries the rise in the capital/labour ratio accounts for only a small part of the long-term increase in labour productivity, and efforts are now being made to assess quantitatively the contribution of other factors. Here, it may be noted again that while there is some evidence of a statistical association between the research intensity of an industry, as measured by the ratio of research activity to output, its rate of productivity change and its rate of growth, there is no evidence of causality.

Much that is in this paper is not new, but national trends are brought together at an international level. For example, the high ratios of research and development expenditure to gross national product in the United States and Great Britain are clearly related to the high level of expenditure on military research and development Only a part of such expenditure appears to be included in the French estimates Again it is emphasized that economic growth is accompanied by a transformation of the production system, in which process technical innovation plays a predominant part Consequently, the relative growth of the manufacturing sector within the economy usually entails a rise in the research ratio. There also now seems to be a general tendency towards increased research and development expenditure in all industries because of the introduction of new equipment, materials and methods affecting all types of production The pattern of industrial growth has become increasingly complicated and there seem to be strong technological, economic and social forces tending to create a similar industrial pattern for research and development irrespective of national peculiarities

Empirical evidence on the relation between monopoly and research is inconclusive, and the paper suggests that the attitude of management may be much more important than the particular competitive situation of the firm. Furthermore, many of the returns on research and development investment may be social and cannot be pre-empted by the individual firm, being spread over all firms in the industry or even throughout the economy In spite, however, of the great increase in research and development activity, the report concludes that there are good reasons for believing that this activity is often still below that desirable for efficient and sustained economic growth It seems inherently improbable that the scale on which Governments supplement civil research and development in sectors other than nuclear energy is anything like sufficient, moreover, it appears reasonable to undertake a diversion of resources which would yield greatly increased returns, in terms of economic growth and social progress

* Organization for Economic Co-operation and Development Ministerial Meeting on Science Agenda Item 111 (Background Paper)—*Science, Economic Growth and Government Policy* Pp 66 (Paris Organization for Economic Co-operation and Development, 1963)

† Organization for Economic Co-operation and Development *Science and the Policies of Governments The Implications of Science and Technology for National and International Affairs* Pp 55 (Paris Organization for Economic Co-operation and Development, 1963)

This is the angle from which, in contrast to the Advisory Group's report, this background paper approaches the problem of Government policy, and in this second part of the survey the discussion is supported by a short bibliography and some further figures comparing the finance of research and development by Government in various countries In all the countries considered, research in the universities draws its funds mainly from Government sources either by direct grants or, particularly in the United States, from contracts However, on the whole, Governments have been loath to recognize their responsibilities concerning the level and balance of national effort in research and development Government policies have evolved somewhat haphazardly, sometimes influenced by the special interests of Government departments and sometimes by lines of thought advocated in influential scientific circles

The apparently unco-ordinated growth of research and development carried out or financed by Governments is attributed to the interaction of varying and sometimes divergent needs· it is over a multiplicity of motives that the difficulty of formulating a national strategy for science and technology arises. The spontaneous human need for wider and deeper knowledge, the need to solve specific social problems, as in health, nutrition. atmospheric pollution or road safety, and the needs of national defence may have points in common with needs related to the promotion of economic growth, but may also sometimes conflict It is suggested in this paper that practically there is no such thing as a science policy but rather a series of separate science policies aimed at different objectives The real question is whether these different policies can be co-ordinated, or at least worked out so as to support each other

It could, of course, be argued that this is a terminological quibble and that to achieve such co-ordination is in effect to formulate a scientific policy. or rather a policy for science and technology What lies behind it all is the allocation of resources and the choice of objectives as, in fact, in foreign policy, which could equally be said to represent the summation of a series of foreign policies towards different countries which likewise has regard to available resources The pragmatic test is inescapable and there is a good deal in this background paper to support the attitude which Lord Hailsham has consistently adopted. Promotion and co-ordination at Government-level of scientific research present an infinite complexity of problems which no group of men, however experienced. can handle effectively without being able to rely on basic and comprehensive data

These data, the paper points out, are often lacking, and it is regarded as one of the great merits of the new scientific councils that they have shown that no efficient work can be done without an overall view and without accurate and searching analyses of the state of scientific research and of the conditions for its development That touches one of the weak points of Lord Hailsham's position, for it can scarcely be claimed that he has provided sufficient drive to secure the data that are lacking It will be noted, too, that the paper insists that the value of the councils on general science policy which a number of countries have already set up depends largely on the efficiency of the permanent departments which support them—staffed not only with scientists but also with economists, financial experts and administrators, and competent to compile the basic data, conduct the enquiries and present the general synthesis and analyses needed

This whole concept is diametrically opposed to Lord Hailsham's conception of the Office of the Minister for Science and its staffing, though it should also be noted that the paper appears to look to the National Economic Development Council to co-operate with the Office of the Minister for Science in this field That, however, is a matter which raises rather large issues, both in respect of the place of the Council in the structure of Government and in relation to Parliament While the view could reasonably be held that the same staff could appropriately serve the Council and the Minister for Science in many matters in this field, there is rather more involved, and the practicability of such a proposition clearly depends on the views that may be taken as to the permanent position of the Council in the structure of Government

These implications, which go far beyond scientific or even economic policy, were put fairly enough by Prof W J M Mackenzie in his two broadcast talks on administrative reform early this year Prof Mackenzie fully recognized the decisive importance of the Director of the Council and his staff and also seemed more disposed than Prof Brian Chapman in his recent book, *British Government Observed* (see *Nature*, 200, 198; 1963), to welcome the development So far, however, as a scientific policy for economic growth is concerned, some such permanent staff must be provided at the most appropriate point if that policy is to achieve the two main objectives desiderated in this background paper first, assessing the possibilities and needs of private and public enterprises with respect to research and development and defining the lines on which Government action is likely to be most effective, secondly, choosing the overall priority objectives which should determine Government action

In this context, the paper makes some comments which are highly pertinent in considering the various statements that have recently been put forward, such as that from the Federation of British Industries on *Civil Research Policy* (see *Nature*, 199, 725, 1963) and the more recent statement, *Labour and the Scientific Revolution*,* which was discussed at the Labour Party Conference at Scarborough It is urged, for example, that Government, by an appropriate policy, can provide encouragement and effective aid, not only to particular enterprises or economic sectors but sometimes to the economy as a whole Above all, Government policy should seek to create a psychological climate favourable to research and innovation Experience has shown that campaigns designed to inform and convince business enterprises of the importance and profitability of research are often effective in converting even the most reticent managements to the idea that research is a paying proposition Here it would seem that much could be done without party politics entering into it There is much common ground in the ideas advanced in the Labour Party's statement of policy and those to which Lord Hailsham has already committed himself

The background paper also makes the important point that the Government should never bear the entire risk in development work and equally that in the event of success the Government should share the profits It enters a caution as to the extent to which the considerable tax concessions in respect of fundamental research which many countries make to private enterprise are important the real problem is to enable business enterprises to finance applied research and development On the role of education in science policy, it emphasizes many of the points which are made in the Labour Party's statement and in the report from the Federation of British Industries, some of which found expression also in Sir Eric Ashby's presidential address to the British Association It stresses also a point in regard to fundamental research that is sometimes overlooked—that the multiplicity of sources of finance is to some extent a prerequisite for the birth of new ideas and should not be eliminated.

---

* *Labour and the Scientific Revolution* (A Statement of Policy Submitted to the Annual Conference of the Labour Party, Scarborough, 1963) Pp 4 (London Labour Party, 1963)

On the priorities of a scientific policy for economic growth, it reiterates that the first step is to make as thorough an analysis as possible of each economic sector with regard to its needs for research and development, taking into account the objectives of the economic plan From these sector analyses a synthetic view should be worked out by the bodies responsible for the co-ordination of scientific research, in co-operation with the economic planning authority and also with industry This view would guide the choice of methods or forms of Government action and determine any necessary programmes of research and development, and finally lead to the decision concerning what research training programmes are required

This emphasis on the importance of the economic element is particularly interesting in view of a similar emphasis placed on that factor in the papers contributed to a symposium which have recently been published under the title *Public Expenditure Appraisal and Control* (see p 724 of this issue of *Nature*) The symposium attempted more particularly to demonstrate how economics can be employed as a useful method for gauging the efficiency of Government spending Several of these papers are highly relevant to the kind of appraisal that is required to-day in assessing the allocation of resources Taken, moreover, with the work of Stone and Brown at Cambridge, whose attempt to devise a mathematical model of the whole economy Dr Patrick Rivett described in his address to the Operational Research Society last November as potentially the most important demonstration yet made of what modern computing devices can contribute to the study of the problems of national growth, they provide compelling evidence of the need to bring much wider resources to the work of Government.

The background paper is concerned much less than the report—*Science and the Policies of Governments*—with the actual organization required for the formulation and implementation of policy, leaning to the view that the structure of Government in any country must reflect the national characteristics as well as the purposes it is required to serve What needs to be stressed at the moment is that those purposes must affect the organization of Government, particularly so far as science is concerned, more than Britain has hitherto been disposed to admit Lord Hailsham's more recent utterances seem to indicate acceptance of this, and it seems implicit in the Labour Party statement without being elaborated Both also appear to recognize the very great importance of investigations in applied sciences and engineering attracting the best possible brains—as is emphasized in the background paper

The Labour Party proposes to build on the experience of the National Research Development Corporation, through the creation of large Government organizations for applying science on a massive scale in civil industry, and would appear to go beyond anything contemplated by the group which prepared the paper on *Science, Economic Growth and Government Policy* On the other hand, the proposal to strengthen the scientific staff of Departments, such as the Post Office, the Ministry of Works the Ministry of Transport and the Ministry of Education, seems to be much more in harmony with the ideas expressed in the paper It is also interesting to note the recognition that the opportunities which technological development offers will not be realized without a new climate of opinion both in industry and in the nation generally

This is a matter of education and will require more than the expansion of facilities for adult education and industrial training. The statement fully recognizes, too, that the Trade Unions have a crucial part to play and that a new mobility and readiness to change both skills and jobs will be demanded For all that, the attitude of the Trade Unions to trade union reform as manifest at the last Trades Union Congress scarcely warrants optimism, but with so much ground in common it should not be impossible for the political parties to co-operate in this immense task of education which is prerequisite if the challenge of the scientific revolution is to be met The meeting in Paris of the Ministers for Science itself contributed both to the task of education and to the accurate assessment of the recommendations of the Robbins Committee and the Trend Committee

THE WORSHIPFUL SOCIETY OF APOTHECARIES OF LONDON

A History of the Worshipful Society of Apothecaries of London

Vol 1 1617–1815 Abstracted and arranged from the manuscript notes of the late Cecil Wall by the late H Charles Cameron Revised, annotated and edited by E Ashworth Underwood Pp xiv + 450 (27 plates) (Published for the Wellcome Historical Medical Museum by the Oxford University Press, London, New York and Toronto, 1963) 55*s*

A M. A MOORE, Master of the Society, 1961–62, writes in the foreword to this *History* "The late C R B Barrett published, in 1905, a *History of the Society of Apothecaries*, which has hitherto done good service as a readable and generally available source of information on its subject It was obvious, however, that much additional and important matter for an adequate history of the Society was bound to be discovered by a systematic and adequate examination of the great wealth of documents and records, which it has inevitably accumulated during the nearly three and a half centuries of its continuous activity The Society was fortunate in having as Archivist one of its Past-Masters, the late Dr Cecil Wall When Dr Wall died in 1947, he left in typescript an exhaustive document of more than 300,000 words, dealing with every aspect of the Society's activities from its first separation, as a distinct 'mistery', from the Grocers' Company in 1617, down to its specially important period of constructive and controversial effort, in the middle of the nineteenth century Dr Wall's death, when his labours had reached this stage, left the Society in some doubt concerning his intentions At this junction, Sir Hugh Lett, then Master of the Society, approached the Wellcome Trustees with an appeal for their assistance in dealing with the problem The Trustees after examining Dr Wall's material with expert advice from Dr Ashworth Underwood, Director of the Wellcome Historical Medical Museum, offered to make the financial provision required for such an expert re-arrangement, condensation, and substantial rewriting of Dr Wall's material, as would produce an authoritative history of the Society, in a book of the dimensions and character likely to meet with general appreciation They were fortunately able to enlist the interest in this project of Dr Hector Charles Cameron, whose experience and achievements in medical and scientific history were already well known The Trustees' offer, and Dr Cameron's suggested services in giving effect to it, were gladly accepted by the Society's Officers and the Court of Assistants

"The Wellcome Trustees had further suggested, for the Society's consideration, that Dr Cameron's manuscript, when completed, might be submitted to Dr Underwood, for inclusion if acceptable in the Main Series of Publications of the Wellcome Historical Medical Museum, and this proposal, which would relieve the Society of any expense and trouble contingent on the publication, was also accepted "

I would merely like to add to the foregoing that, in my view, the book would be the gainer by a colour photograph of the Courtyard of Apothecaries Hall, London, such as was specially painted for the July 1954 issue of *The Glaxo Volume* by I C Moody Moreover, the pictures of King James I and of Francis Bacon could add to the value of the volume by being reproduced in colour

SOLID-STATE PHYSICS

Solid State Physics

Advances in Research and Applications Vol 12. Pp xvi+459 114*s*. 6*d* Vol 13 Pp xv+482 103*s* 6*d* Vol 14 Pp xv+519 114*s* 6*d* Edited by Frederick Seitz and David Turnbull (New York and London Academic Press, 1961–63)

Theory of Lattice Dynamics in the Harmonic Approximation

By A A Maradudin, E W. Montroll and G H Weiss (Solid State Physics Advances in Research and Applications, Supplement 3) Pp viii+319 (New York Academic Press, Inc , London Academic Press, Inc (London), Ltd , 1963) 80*s*

THE general excellence of the *Solid State Physics* series scarcely needs to be recorded. it can by now be taken for granted

The 'substantive' articles in Volume 12 include a review by H Inokuchi and H Akamatu of electrical conductivity in organic crystals The conduction in such materials is, of course, not done well, and one is surprised—as Dr. Johnson would have been—to find it done at all It seems, however, that 'organic semi-conductors' are by no means rare forms of molecular crystals and that they are beginning to be understood K Mendelssohn and H M Rosenberg achieve the useful and apparently difficult feat of writing about thermal conductivity of metals at low temperatures in a way which is at once lucid, readable and complete Finally, G Leibfried and W Ludwig survey anharmonic effects in crystals in a way which will not be very helpful to the general reader but invaluable to research workers in lattice dynamics Their article includes quite a lot of original work

There are two articles on 'techniques' in Volume 12 an experimentalist's vade-mecum on the subject of hydrothermal crystal growth by R A Laudise and J W Nielsen (complete with beautiful pictures of growing crystals, diagrams of autoclaves and so forth), and a theoretician's potted guide to group theory and crystal field theory by C M Herzfeld and P H E Meier A feature of this article is the index of references to character tables, tables of direct products of irreducible representations and tables of explicit base functions for the point groups

Volume 13 exhibits a similar balancing of topics The semi-conductor lobby provides us with a comprehensive account of electron spin resonance in semi-conductors by G W Ludwig and H H Woodbury; this tool appears to be particularly powerful when applied to the investigation of impurities J J Gilman and W G Johnston explain, with the help of illustrations, how dislocations in lithium fluoride may be investigated by means of etch pits The pictures look rather like rills on a lunar landscape. C. K. Jørgensen writes about chemical bonding (as inferred from visible and ultra-violet absorption spectra) from a point of view which will be unfamiliar to most physicists Is he a missionary talking to cannibals or a cannibal talking to missionaries? There is little doubt that S S. Mitra who writes about the vibration spectra of solids, is a cannibal His feast included, among others, C. V Raman, and has proved somewhat indigestible

The 'techniques' part of Volume 13 involves a fascinating article by F P Bundy and H M Strong, well known for their work on diamond synthesis at the General Electric Co , on the behaviour of metals at high temperatures and pressures. There is indeed much more than techniques to be found here known data on resistivity, compression, phase diagrams, thermoelectric power and the curious catalytic properties of transition metals which enabled the diamond synthesis to proceed Naturally perhaps, the last topic is skimpingly done There is no reference to Henry Eyring. Theoretical technicians will be well pleased by E I Blount's account of the 'formalisms' of band theory This article is centred on the Wannier representation It draws together scattered results in an intelligible and intelligent way and includes some original work

The 'mixture' of Volume 14 is not the standard one There are three high-level articles on special problems, namely, "g Factors and Spin-Lattice Relaxation of Conduction Electrons", by Y Yafet; "Electron Spin-Resonance Spectroscopy in Molecular Solids", by H. S Jarrett; and "The Theory of Exchange in Insulators and Semi-Conductors", by P W Anderson. Each of these articles is authoritative, critical and complete, but they demand much background knowledge from the reader The fourth article—a book within a book—is an account of molecular motion in solid-state physics by N Saitô, K. Okano, S Iwayanagi and T Hideshima It reviews competently theory and experiment in a field which is (literally and figuratively) amorphous

Theory of Lattice Dynamics in the Harmonic Approximation, by A A Maradudin, E W Montroll and G H Weiss, is a masterly account of the 'active centres' of a popular and important field The topics covered include the role of critical points in phonon spectra, the effects associated with defects, surface effects and atomic correlations There is no other convenient account of these subjects available, and they are here treated with clarity and elegance The theory of ionic crystals is the only obvious 'gap' Is it too much to hope that it will be filled by someone like Rosenstock ?

R O DAVIES

ANIMAL PATHOLOGY

Pathology of Domestic Animals

Vol 1 By K V F Jubb and P C Kennedy Pp xv+477 (New York and London Academic Press, 1963) 128*s* 6*d*

FOR long a notable omission in the ever-expanding veterinary literature has been the absence of a modern authoritative text, in English, on morbid anatomy and histopathology This book, the first of a two-volume work on the pathology of domestic animals, goes far towards filling the gap It is particularly opportune that it should come at the present time when there is a growing interest in, and awareness of, the importance of comparative pathology Although the work has been designed primarily for the teaching of veterinary students it will also serve as a useful guide to those medical pathologists who turn their attention to apparently analogous conditions in man and animals It will be useful to the research worker in experimental pathology, and non-veterinarians in particular will find useful the brief descriptions of some of the normal variations which occur in different species of animals Equally valuable to all are the side-by-side illustrations of some normal and diseased tissues

Volume 1 presents a fairly detailed account of disease processes affecting bone, joints and synovial membranes Organ pathology is discussed on a systematic basis and here includes the respiratory, hæmopoietic, endocrine, circulatory, and the genital systems Volume 2, which is to be published shortly, will deal with the remaining systems and organs of the animal body There is, rightly, no account of general pathology because, as the authors point out, this subject is adequately covered in many standard text-books The gross and microscopic structural changes in the various tissues are presented, together with sufficient information on altered function and consequent clinical signs to stimulate and interest the student The text is well illustrated with photographs and photomicrographs of excellent quality which clearly indicate the essential features of the lesion under discussion A minor criticism here might be that some of the illustrations are wasteful of space, for example, two full-page photographs to show adventitial placentation in the ox.

The excellent bibliography is a major strength of the book. Appended to each chapter are many selected references which will be useful to a wide range of readers References are given to key papers in the related fields of virology, bacteriology, parasitology, oncology and genetics where these abut on to the main subject of pathology It is, however, unfortunate that some, at least, of the references are not 'tied in' to the text, because the authors in some of their discussions do not always distinguish between what is fact and what is speculation This is an obvious drawback from the point of view of the student and the non-specialist reader The references are well set out and there is a good and accurate index Typographical errors are rare, the book is well produced and of the high standard associated with the publishers It is probable, however, that the cost will be prohibitive for many students

Inevitably in a work so extensive as this there are bound to be omissions, and the relative emphasis placed on some subjects will not meet with everyone's approval In the chapter on respiratory disorders, a brief résumé of the modern concepts of the structure of the alveolar epithelium would have helped to clear some of the confusion in the text, and the section dealing with the interstitial pneumonias could, with advantage, be amplified and more attention directed to the pathogenesis of these diseases Students of comparative pathology will be disappointed with the section on arterial disease There is no discussion of atherosclerotic lesions in pigs or cattle (but, in fairness to the authors, they do point out that arterial disease is of no economic importance in domestic stock) In their introductory remarks, the authors state that all they have to say on a specific disease is said in one place under the organ system which is most appropriate They waive this general rule in several places but chiefly in the sections devoted to the genital systems It is, however, very surprising that in the chapter on the cardio-vascular system no mention is made of the virus of swine fever ('hog cholera') as a major cause of vascular damage in swine and hence as the prime cause of the protean lesions of this important disease It is probable that swine fever will be described in Volume 2, but the essential lesion is one affecting the small blood vessels and as such should receive attention in this section

In their preface, the authors do not attempt to justify their book because, as they say, a good book is its own justification This is such a book; it will find and retain its place on the shelves as an indispensable standard work of reference A R JENNINGS

THE DEVELOPING WORLD

Our Developing World

By L Dudley Stamp Pp. 195. (London: Faber and Faber, Ltd, 1963) 8s 6d

THE population of the world to-day is more than 3,000,000,000, probably almost double the population in 1900 This means that the past sixty years have seen a growth equal to that in the entire previous history of mankind This sobering thought becomes frightening when we look into the future In 1951 the United Nations estimated the world population for 1980 as between 2,976,000,000 and 3,636,000,000 They revised these figures in 1954 to give estimates between 3,295,000,000 and 3,990.000,000 and again in 1958 to between 3,850,000,000 and 4,280,000,000

These figures are quoted by Prof Dudley Stamp in *Our Developing World*, and he points out that they show not only that our knowledge of the numbers of mankind is improving, but that they are constantly showing previous estimates to be too conservative By 1980 world population will probably be considerably more than 4,000,000,000 and, by the end of the century, between 7,000,000,000 and 8,000,000,000 It is difficult to write about the future relationship between population and resources against so dynamic a situation, and Prof Stamp's experience shows this The core of his latest book was a series of talks (the Patton Foundation Lectures at Indiana University) published in 1952 as *Land for Tomorrow* This was brought up to date for an English edition, in 1953, called *Our Undeveloped World*, a book which, he says, should now be read "almost as historical documents" It had to be re-written in 1960, when it was called *Our Developing World*, and some of the figures had to be brought up to date again for this paper-back edition

Prof Stamp sets the population explosion against a more stable background, that is, the amount of land available and the basic facts of climate and soil these are the given elements from which man must obtain his food But the relationship of man and land is by no means simple The history of mankind is that of developing techniques to produce more and more food cultivation, domestication, the invention of the hoe, the plough, the harnessing of power, rotation, irrigation, fertilization—all these have dramatically changed the relationship, and Prof Stamp discusses the latest advances, mechanization and 'chemicalization', to show that potential changes are as great as those of the past But another fact is equally evident that this progression has been most uneven Whereas revolutionized techniques enable advanced communities to produce the food they need with only a small percentage of primary producers, others are still at subsistence-level Indeed, the majority of people are still setting the balance between Nature and society at starvation-level Strangely enough, the more technologically advanced countries depend to an increasing degree on these same underdeveloped countries which supply, for example, much of the world's oil, most of its copper, tin and bauxite The table of their contribution in this respect to the world's economy makes thoughtful reading

Meanwhile, the problem of equating an exploding population with food supplies is of paramount importance, and demands all the skills of the most advanced technologies Prof Stamp's admirable little book puts these problems succinctly and clearly without pretending to attempt the answers It gives the more general reader a real appreciation of the situation against a more geographical background than is usual It cannot fail to make the reader conscious of the great dilemma of the age, and for this we are in debt to Prof Stamp for one more expression of his concern with these problems

Public Expenditure

Appraisal and Control. Edited by Alan T. Peacock and D J Robertson. Pp viii+168. (Edinburgh and London Oliver and Boyd, 1963) 21*s*

THE publication as a separate volume of the ten papers contributed to a symposium on the appraisal and control of public expenditure is timely when not merely the efficiency of Government control in general has been brought in question, for example, by Prof Brian Chapman in his recent book, *British Government Observed* (*Nature*, 200, 198, 1963), but also the effectiveness of Government organization has been re-examined by the Trend Committee

Originally, the papers were published in the *Scottish Journal of Political Economy*, and while books by Basil Chubb and S H Beer have in recent years discussed the control of public expenditure from the administrative point of view, these papers concentrate on the economic side and indicate, for example, the value of Dr R McKean's systems analysis in decisions on Government spending The subject is one which is likely to grow in importance, and as Prof A T Peacock shows in his paper on ' Economic Analysis and Government Expenditure Control", while the way forward has been pointed by the Plowden Report, for example, extensive adoption of economic analysis is likely to await a major change in the attitude of the electorate to public spending—or, it might be suggested, some rational understanding between political parties

The specific problems of defence expenditure, health service policy, the allocation of expenditure in the electricity supply industry and the control of subsidy expenditure in agriculture are discussed by Dr McKean, Mr J Wiseman, Dr R L Meek and Mr G F B Houston, respectively Others deal with the appraisal of Government purchasing, controlling the Government's wage bill and the growth of Government expenditure in the United Kingdom since 1790 In discussing problems of expenditure control in local government, Mr L Boyle comments that many universities appear to have been singularly remiss in providing facilities for studying public finance and political science He suggests that a much closer contact is desirable between the academic world and the field of practice so that senior officials in the public service can communicate their problems to the universities, enabling research to be conducted into those problems, and thereafter benefiting from the results of such research.

Such a remark itself attests the significance of this volume to which Mrs Ursula K Hicks contributes an epilogue on choice, efficiency and control in the public services, which has some sound comments to make on the Plowden Report

Experiments in Physical Chemistry

By J M Wilson, R J Newcombe, Dr A R Denaro and Dr R M W Rickett Pp xii+290 (London and New York Pergamon Press, 1962) 21*s* net

EXPERIMENTS in Physical Chemistry is intended for use by students reading chemistry to honours degree standard The form of presentation is most attractive. Each experiment is assigned to one of three sections, the sections differing in the degree of complexity of the operations and the associated theory

Each experiment is prefaced by a discussion of the theory involved The discussions are incomplete but serve to relate the book with theoretical texts Next, the apparatus required is described Diagrams are useful, and firms manufacturing the equipment to be used are listed The method to be followed is then given, and here the text is weak More detail is required, too much initiative is required of the student For this reason the book might prove a valuable addition to the teacher's library, the student reaping the benefit second-hand

The book has an efficient index and the contents are set out very clearly One hundred and two experiments are presented and they are selected to cover the wide range of physical theory and technique Although most of the experiments are of college standard, there is a great deal here to interest the very able sixth-form pupil, and the book would be a very useful additional source of ideas for end-of-term laboratory work D C FIRTH

Organic Chemistry Laboratory Operations

By W B Renfrow and P J Hawkins Pp viii+216 (New York The Macmillan Company; London The Macmillan Company, New York, 1962) n p

THIS book covers a very wide range of techniques Its introductory chapters on distillation, extraction, melting and boiling point determinations are familiar ground for a pupil in the lower sixth form The final chapters on high-pressure hydrogenation and infra-red spectroscopy are the province of an honours student in his final year.

A range of preparations are given and these illustrate well the basic reaction types of organic chemistry Many of the experiments are done using unfamiliar materials For example, *p*-xylene is sulphonated and not benzene Saturation and unsaturation are illustrated using *cyclo*hexane and *cyclo*hexene and not the more familiar methane and ethylene The general theme, worthy of close attention, is that reactants must be easy to handle, reactions must work quickly, and the products be easy to isolate

Each chapter includes a discussion illustrated by clear diagrams, also an equation and a suggested mechanism for the reaction A problem is given at the end of the chapter and is designed to test the student's understanding of the theory Between theory and problem there is a method This is adequate in earlier chapters on elementary experiments, but quite the reverse later in the book when advanced work is under discussion Students are asked to see the instructor for working instructions!

The early part of the book is well worth reading at the bench, the latter part has no place in the laboratory

Mild-Moderate Forms of Protein-Calorie Malnutrition

Symposia of the Swedish Nutrition Foundation, Bastad, August 29–31, 1962 Edited for the Swedish Nutrition Foundation by Gunnar Blix Pp 159 (Stockholm Almqvist and Wiksell, 1963) Sw Kr 35

TOWARDS the end of 1961, the Swedish Nutrition Foundation came into being, mainly through the financial support of the Swedish food industry Among its projected activities is an annual symposium The first of these was held in August 1962 This book records the papers read then, and a summary of the discussion There were 13 contributions, all by workers who had a direct concern in the problem of protein-calorie deficiency These included research workers from the United States of America, Africa and Central America, as well as a representative from the World Health Organization and one from the Food and Agriculture Organization The contributions dealt with the clinical and biochemical features of the condition and with related questions such as protein and calorie requirements, methods of assessment of physical condition, the use of protein-rich foods for prevention, and an exhaustive and provocative article on the evaluation of the nutritive value of protein

Together these papers form an excellent review of the present-day situation The discussion is especially valuable in emphasizing how much we still have to learn about this, the commonest of all forms of malnutrition The book is beautifully produced and a pleasure to read There are very few and quite unimportant misprints, a most praiseworthy effort for a book produced and printed in Sweden

JOHN YUDKIN

TELEVISION IN MEDICAL EDUCATION

By C. E ENGEL

Department of Medical Illustration, Guy's Hospital Medical School, London

IT is perhaps reasonable to ask why television should be considered at all seriously in the context of medical education, it is still a relatively novel technological development and primarily applied to mass entertainment. As television reproduces movement accompanied by sound, it could in any case be argued that the motion picture film should fulfil whatever useful functions are claimed for television However, the film, like a paper in a journal or a chapter in a text-book, must be complete and able to stand on its own Once projection has been started, it is difficult to stop the film and repeat sequences already viewed Thus the ideas, concepts, phenomena or procedures to be portrayed by the film must be developed most carefully, so that even the less well-informed members of an audience do not lose comprehension, as the remainder of the film might otherwise be devoid of meaning for them For this reason the production of films is a time-consuming and not inexpensive undertaking Films are frequently not only inflexible but also impersonal and tend to convey a sense of unreality Because academic teaching is essentially individual and adaptable to the varying needs of each individual teaching situation and audience, few lecturers are prepared or indeed able to use the conventional full-length film in their teaching[1]

Television, however, offers a number of potential advantages These may justify serious investigation into its effectiveness in the context of the present situation where a rapidly increasing volume of information has to be imparted, in a restricted period of time by a limited corps of teachers, to undergraduates, to those reading for higher degrees and to practising graduates It may, therefore, be helpful to consider the educational problems in which television might possibly be of assistance Students in the medical school represent a captive audience, as it were, for they can be reached by the lecturer at a time and place of his choice General practitioners, however, work as individuals and are widely separated from each other, so that a lecturer finds it much more difficult to meet a number of them all in one place and at the same time These are, therefore, two fundamentally different situations which might be considered separately as intramural and extramural problems

Intramural Problems

All learning relies to a large extent on repetition, and, particularly in medicine, a great deal of learning is concerned with objects rather than with concepts, so that visual experience must play an important part Yet an adverse staff/student ratio constitutes a serious obstacle to the ideal where each student in the medical or dental school can see what is being demonstrated not only really well but also frequently and repeatedly

Image Magnification and Optimum Perception Many objects, phenomena, reactions and clinical appearances are quite small so that adequate demonstration would require individual presentation to each student or in any event to very limited groups of students Restricted teaching staff makes this impracticable and repetition by one lecturer soon becomes tiring and uninspired Television, because it can reproduce an optically magnified image on a virtually unrestricted number of receiver screens in one or several rooms simultaneously, may help to solve this problem The lecturer can still be in the same room or ward, as his students where he can now teach with the aid of the enlarged image The recording television camera can also be in the same room and, indeed, be operated by the lecturer himself The receiver image is so bright that daylight or artificial light need not be excluded

This situation offers each student the same magnified view from the 'ideal' observer's position The lecturer is able to switch on or off as he thinks fit, so that he need show such images and associated sounds only at the instant when they serve his exposition. The students can interrupt if they cannot see clearly enough, or require further explanations This active participation by the students is likely to help the learning process, and it enables the lecturer to repeat parts of a demonstration, possibly in a modified form, according to the students' needs

Numerous examples could be quoted and a few of those which have been reported in the literature may here be of interest Small television cameras have been attached to microscopes, so that the lecturer can point out specific structures which the students can then identify under their own microscopes during classes on histology[2]

Cameras with lights attached have been suspended above a demonstration table[3], set up to record from surface-silvered mirrors or fitted to a mobile support for attachment to dissection tables for macroscopic demonstrations during courses on anatomy At Guy's Hospital Medical School such macroscopic demonstrations have been used to give students advance information or pre-knowledge before they proceeded to carry out their own dissections This approach was subjected to a series of objective tests in collaboration with the Institute of Education, University of London[4].

Both microscopic and macroscopic television can be used for better vision during the demonstration of animal experiments in physiology[5] and pharmacology It is, therefore, easy to imagine the uses of television during clinical rounds and clinico-pathological joint meetings when relatively small lesions, either on the patient or in a histological preparation, are to be demonstrated to a large number of students Equally, a television camera can offer a close-up view to the students, however many may be assembled to watch a post-mortem examination

Although students may not be required to watch a large number of surgical procedures, television can provide a better view than the conventional observation gallery Ruhe[6] has reported on a well-planned installation where the lecturer and his students are given a close-up view on television receivers in the observation gallery, while they can also see and hear what is going on in the theatre below A by-product of such an arrangement is that every member of the surgical team, not only the surgeon and his assistants, can see what is going on[7], quite apart from the obvious reduction in the risk of cross-infection which results from keeping all but essential personnel out of the operating theatre

Apart from the foregoing instances, which represent largely passive learning, there are many situations when students are taught essentially practical manœuvres and techniques While it may well be impracticable to assign one demonstrator to each student, a single teacher can demonstrate to a television camera, so that the whole firm or class can see At least one film has been tested successfully in the role of simultaneous multiple-student technique-instruction[8] This film may have become somewhat outdated through subsequent changes in the technique itself, television, however, can always be up to date and has the additional advantage of complete flexibility. Merrill[9] has proved by experiment that the time taken by students in preparing a tooth for an inlay was reduced by almost 40 per cent and that the quality of their preparations was considerably better, when compared with the work produced by more orthodox methods of instruction Best results and the greatest saving in time were achieved when the students were given an opportunity to complete a discrete stage of the practical work before the next manœuvre was demonstrated and explained to them on the television screen.

Image Transportation One problem, then, to which television may be applied is visual magnification, so that every student can see as well as the demonstrator, examining physician or surgeon A further problem is how to demonstrate related events, or phenomena which are separated in space This is normally difficult to organize or, indeed, impracticable because of time available, number of students, possible risk of infection or restricted space as in a research laboratory[10], sometimes the teaching situation might be adversely affected, as during a psychiatric interview, if too many observers are present

The television camera can be called on to bring images to the lecture theatre, classroom or laboratory from as widely separated locations as other laboratories, wards, out-patient departments, X-ray department, delivery room, operating theatre and post-mortem room Only the number of cameras available for distribution to these locations and the versatility of a switchboard restrict the possible sources from which the lecturer can show one or more remote but relevant events to his students Which locations are connected to the students' receivers and the sequence in which events from different locations are shown is entirely at the discretion of the lecturer, so that he can make use of these facilities just once or repeatedly during his exposition He can also use the televised picture and associated sound to make comparisons, either in sequence or by juxtaposition on adjacent receivers This need not, of course, exclude the complementary use of the more conventional aids such as lantern slides, blackboards or short film units

Apart from helping to solve the problems already mentioned, this use of television may claim other advantages When the transmitted sound is reduced in volume, the lecturer can add his own explanations while the visual information continues to be received by the students· his comments and active participation by the students do not, of course, interfere with the event which is being televised. Particularly extensive use has been made of this method in the teaching of psychiatry[11] Markee[12] has shown that the possibilities offered by this ability to bring information to the assembled students have by no means been exhausted yet On the premise that knowledge largely acquired from visual information ought to be tested by posing visual problems, he has televised dissections, specimens, photographs, drawings and patients, with superimposed written questions to test his students of anatomy The results were statistically evaluated in comparison with the performance of the same students in other, more orthodox, tests; he found that this method could also be used successfully to establish a student's knowledge and his ability to apply such knowledge appropriately Markee satisfied himself that television could be more versatile, more searching and less time-consuming than the usual method of letting students file past a series of exhibits annotated with questions

Image Multiplication One more problem, that of bringing the same visual information to students who are not assembled in one room, may be solved by television This method is already used in other academic subjects where the student audience is too large for one lecture theatre, and experimental data on its relative efficiency are now available[13] In medicine those schools which have adopted the unit laboratory system have found the transmission of visual and verbal information from one room to the various laboratories both efficient and time-saving[14]. A two-way sound-link between students and teacher is a necessity in this situation

The Clinical Center of the National Institutes of Health at Bethesda, among other American teaching centres, has installed the necessary wiring, so that cameras and receivers can be connected in a large number of rooms[15] This makes it possible to show in study rooms, library cubicles, teaching rooms attached to wards and in operating theatre galleries anything deemed of interest to students—from simple references to relevant, up-to-date information in journals to interesting radiological examinations, rare or unusual conditions seen in out-patients, a birth or parts of a surgical operation This offers visual experience and learning by repetition without having to call the students together or away from their places of work

Image Transformation Television, with specially sensitized tubes and in conjunction with other devices, can convert invisible radiation into visible images In this way, radiological examinations[16,17], differential ultraviolet transmission by cell components[18] and infra-red penetration of the skin to reveal the subcutaneous venous system can be demonstrated to students Infra-red sensitive television tubes can also be used to demonstrate events and processes which can only take place in the dark. Of these potential applications, television radiology is likely to establish itself most readily

Endoscopy The observation of endoscopic appearances by the student has so far been largely restricted to a quick, and possibly displaced, glance through the endoscope, to a photograph or, though rarely, to endoscopic motion picture films The French endoscopes[19] which make use of intense light piped to the distal end through a quartz rod, and such recent developments as a miniaturized television camera[20], which is no bigger than an electric shaver, will make television endoscopy both simple and safe The reproduction of colour must unfortunately wait until smaller, simplified and much less expensive colour equipment becomes available

The further development of fibre optics, where each glass fibre in a flexible bundle conducts a fragment of the image by internal reflexion[21], may before long make it possible to show to students structures and processes[22] on the television screen which are inaccessible to the rigid endoscope Even now television linked to periscopes[23], ophthalmoscopes and operating microscopes[24] may help to increase the student's visual experience well beyond that of his immediate predecessor

Extramural Problems

The needs of the graduate in general practice are different from those of the undergraduate The almost explosive progress of medical science makes it desirable that up-to-date information should be available to the graduate as soon, and as readily, as possible No one journal could attempt to offer such a service and it is doubtful whether this channel of communication would prove entirely acceptable The spoken word alone, as, for example, over the sound radio system, is likely to prove less effective than a combination of sound and sight Not only experiment but also common experience has shown that the face-to-face or 'fireside-chat' situation provides the most effective learning situation Films could be considered in this role, but they are likely to lack spontaneity, the mechanics of production and duplication would lead to undesirable delay, and the additional apparatus in the home might prove a severe handicap

Television has already been considered seriously in the United States[25], and a number of experiments are being staged at the present time What, then, are the possibilities offered by television ?

Open broadcasting, as used in Scotland[26] and by several American centres[27], incorporates a number of obvious advantages and disadvantages Medical practitioners receive the same information simultaneously and thus have a common subject for discussion. They are able to watch and listen either in their own homes, at a society meeting or at a local hospital. Some evidence is already available from the United States[28], and several experimental series of broadcasts are now in operation. The inherent disadvantages are not inconsiderable. The lay public is able to receive the same information, so that the spoken word and the transmitted image must of necessity be rendered unobjectionable and so neutral as to leave the doctor-patient relationship unaffected. Perhaps equally serious is the objection that the doctor must make himself available at a specific time if he is not to miss what may be an essential part of a series of broadcasts. The possibility of repeating each transmission may become impracticable due to cost and lack of broadcasting time, as soon as other professions begin to ask for similar facilities. This restriction of air space and time is not likely to be overcome even if the one remaining free channel were to be allocated exclusively to education.

Scrambled or coded broadcasting offers the advantage of excluding the lay public, so that verbal and pictorial information is freed from any inhibitions imposed by open broadcasting. The disadvantages, however, are the same as for open transmission, with the additional difficulties associated with any special licences which may be required for scrambled broadcasts to minority groups and the need for a special decoding device in each receiver. One experiment is at present in progress in the United States.

Rediffusion, or transmission through land-laid cables, can be organized regionally, so that special local needs can be catered for. This facility and the privacy it offers can be regarded as potential advantages only, as the practical implementation, certainly for non-commercial purposes, is not likely to be realized within the present decade. It is equally unlikely that Great Britain can offer in the foreseeable future the extensive system of coaxial cables and microwave relay circuits which school education makes available to doctors in South Carolina[29].

Video tape in cassettes may eventually prove a more realistic and practical means of up-to-date dissemination of information to a widely scattered group of specialists, in this case, to doctors.

It will then be possible to plan a postal service, so that new information can be presented once fortnightly or once monthly. One or more medical schools could be asked to accept the responsibility for producing the master tape from which the copies are prepared, and as soon as the first set of copies is returned a further programme can be recorded on the same magnetic tape. As tapes will be interchangeable, regional as well as national services will become possible. The doctor who participates in such a scheme will be able to look at and listen to the recorded information with his own television set at a time or at times most convenient to him. He will be able to start, stop and, of course, repeat the tape or any part of the tape whenever he wishes. Eventually complete courses made up of a series of tapes could be added, so that an individual doctor can select the refresher course in which he is most interested. Contrary to film production, video tapes can be re-recorded more readily to keep the information up to date, and particular importance should be attached to this facility if the medium is to be exploited fully.

Cost will be a prominent factor in any discussion. The initial capital outlay will have to consider the necessary television recording equipment at a medical school or other medical centre and the bulk acquisition of the magnetic tape, which can, within reasonable limits be used over and over again. The cost, in thousands rather than tens of thousands of pounds, might be met by the authorities responsible for continuing education. Clerical and postal expenses, as well as the cost of the individual play-back instrument, might well be recovered by a reasonable subscription and hire fee.

However, the technical and financial difficulties are still so considerable that it may be advisable to consider motion picture film as a possible alternative, at least for the immediate future. The 'Technicolor 800*E*' rear projector at a cost of £55 already offers facilities for showing an 8-mm film loop in a plastic cassette which will run for a maximum of 4½ min before it repeats itself. Daylight viewing, the absence of any necessity for threading into the machine or for rewinding, and extraordinary cheapness—approximately £2 for 4½ min of film—are the major advantages of the system. While the film for this apparatus is silent, equipment for the showing of sound film is also becoming available.

Conclusion

Closed-circuit television, whereby electric signals are passed along a cable to reproduce a visible picture, has been shown to possess several properties which may be called on to help in the solution of a number of problems associated with the instruction of students in a medical school.

Television can offer a close-up view from the best possible observer position to large numbers of students; it can bring related visual information to the assembled students from other locations; it can act as the privileged observer and reporter where space is too restricted or when the presence of too many observers is not desirable, it can present the same visual problem to all students during an examination which sets out to test the application of knowledge which has been acquired from essentially visual information, it can distribute visual data from one room to many others so that students need not be assembled but can watch from wherever they happen to be working, it can make use of invisible X-ray as well as ultra-violet and infra-red radiation to present visible images, and it can, with the help of additional devices, such as endoscopes, permit all students to see structures and processes which until recently were seen only by the experienced physician and surgeon.

Although only a restricted number of critical experiments have been carried out so far, notably in the United States, the practical application of closed-circuit television has shown that it can materially help the student to enrich his visual experience and to learn by repetition. However, it must be acknowledged that, like any other device, its effectiveness is closely related to the manner in which it is used. Thus further experimentation will be necessary to establish really effective techniques and to determine the precise teaching situations where it can be expected to contribute most.

As programmed learning, or scientifically planned self-instruction, matures and therefore becomes more universally applied, television will also be called on to make its contribution in the form of stored visual information on video tape or similar media.

The dissemination of up-to-date information to medical practitioners can be achieved by broadcast television. Open transmissions are also received by the lay public, so that the contents and presentation of such programmes are likely to be handicapped. Open broadcasts share with scrambled and rediffusion transmissions the disadvantage of fixed broadcasting times when the doctor must make himself available or miss the programme. The first two methods would involve competition with other potential users for air space and time, and rediffusion is not likely to materialize as a practical reality for some time to come.

Video tape, television from recordings on magnetic tape, may become available at a realistic price. It may then be possible to distribute duplicate recordings to individual doctors for study and re-study in their own homes and in their own time. The ability to erase and record fresh information on the same tape repeatedly should make up-to-date continuing education through television more practical and perhaps more acceptable than present methods through journals and isolated postgraduate courses.

In the meantime, an 8-mm loop film cassette loading rear projector with sound may be a more practicable alternative

It is to be hoped that sufficient funds might be made available to conduct a critical pilot investigation which could be regarded as a reliable guide for the further development of continuing education

CHANGING FOOD HABITS

By Prof JOHN YUDKIN

Department of Nutrition, Queen Elizabeth College, University of London

SINCE the Department of Nutrition was instituted in Queen Elizabeth College, University of London, in 1954, and the courses began for the degree of B Sc (Nutrition), it has emphasized the importance of the social aspects of nutrition In particular, it has felt that we need to know very much more about the factors which determine people's choice of food, in the hope that we may be able to identify those through which nutritionally desirable change may be effected

When, with the aid of a grant from the Leverhulme Trust, a research programme in social nutrition was instituted, it was soon found that one needed advice not only from social scientists engaged in academic studies, but also from those in contact with the market-place The sociologist, anthropologist and psychologist who worked with the food industry had most useful and relevant experience, as had also the food chemist, the food manufacturer, the advertising agent and the market research worker Many informal discussions showed most gratifyingly that there was no reluctance at all from all these to share their knowledge and views with an academic group From this, the idea emerged of a more formal symposium, to which were invited some speakers representing many of the wide range of interests in patterns and trends in food consumption

The result was a symposium, held at Queen Elizabeth College on September 24, 1963, at which Mr James Van den Bergh took the chair, and where eight papers were read, representing the views of the nutritionist, the economic historian, the social anthropologist, the sociologist, the social psychologist, the experimental psychologist, the food chemist and the food manufacturer. The title of the symposium "Changing Food Habits" was deliberately ambiguous, and was meant to convey an interest both in the ways in which food habits were changing, and in the methods which might be effective in inducing change The surprisingly large number of 180 participants attended The eight papers were circulated before the meeting, speakers spent only a short time introducing their papers, so that most of the time was occupied by a very full and interesting discussion

The first paper, by John Yudkin, discussed "The Need for Change" Most people recognized that improved nutrition in the developing countries, especially of the tropics, involves not only an increased supply of food but often a change in the sorts of food which were eaten Whole populations, or groups within them such as women or pregnant women or children, often had habits and social customs which prevented the consumption of nutritionally desirable foods even where they existed But it was necessary not only to assure the consumption of desirable foods but also to try to prevent the consumption of undesirable foods There is evidence from the African countries that increasing industrialization in the developing countries might lead them straight from one sort of malnutrition to another This is because the food manufacturer has two separate functions First, he preserves food, and in so doing increases greatly the availability of food But as well as this, he is able to make completely new foods, based on his ability to separate palatability from nutritional value. Thus, palatability which normally is a guide to nutritional value is so no longer The ability to separate sugar, especially, has been responsible for the vast increase in sugar consumption in the developed countries in the past two hundred years, and may well contribute to the increased incidence not only of obesity but also of coronary thrombosis and diabetes

John McKenzie spoke on "Food Trends the Dynamics of Accomplished Changes". In Britain, there have been many changes in the pattern of food consumption, of varying magnitude Though it took some two hundred years for potatoes to become popular, they are now a basic part of our diet Yet we are not certain of the reasons for this change, nor for the differences in regional consumption Why, for example, do people in London eat three times as much poultry as those in the North of England ? Yet the experiences of some of these changes, such as the enormous increase in sugar consumption, suggests that increasing prosperity in the developing countries will lead to a similar rise We do not know exactly what effect advertising, education and price have on food consumption, except that there is a tendency to exaggerate their influence Other social factors certainly play a part in determining the foods which we eat Yet with the scant knowledge we have, and by the use of the techniques of social investigation, it is now possible to devise programmes, both of investigatory research and of experimental research, which should give us a much better understanding of the determinants of food habits

Margaret Read described "The Role of the Anthropologist" and spoke from her considerable experience of tropical countries She directed attention to the vicious circle of malnutrition → disease → decreased food production → aggravated malnutrition Though traditionally the social anthropologist has worked little in the field of food habits, he has recently been brought into consultation, in many parts of the world, to help in the elimination of the widespread and serious disease of protein deficiency especially in its form of kwashiorkor in children In order to be able to help in such work, an anthropologist needs to know something of the environmental factors affecting a community, its social structure, its domestic life, and its ideas on and attitudes towards food With this knowledge he can proceed to investigate the changes in food habits which are occurring in the country It appears that there are three motivations for such change, prestige, the wish to exchange foods and other products for money, and attempts to ease the burden of work for the women The details of these value systems, however, will differ in different communities

"The Role of the Sociologist in Inducing Changes in Food Choice" was described by David Pickard and Ray Corl People live in groups which each have a particular culture, that is, a particular set of usages, customs and institutions However, an individual does not belong just to one group, but can at any one time be a member of several groups, such as a teenage, working-class army officer The relationship between the individual and his group is expressed as the part which he plays according to his position in the group Change is slow because it tends to be a threat to the stability of the cultural system It can be accelerated, perhaps, by education and propaganda, but only in the direction in which it is already going Much can be done, however, through the innovator, the person who more readily adopts change and whose lead can be accepted While these general statements about the part of the sociologist have meaning in the context of changing food habits there has in fact been very little work done on the sociological background to eating

Cyril Sofer, I Janis and R L Wishlade gave an account of "Social and Psychological Factors in Changing Food Habits" They referred especially to some pilot studies which they had carried out at the Tavistock Institute of Human Relations, designed to reduce the consumption of carbohydrate in a group of housewives Among other factors, the effectiveness of the change in diet could be assessed in those who were overweight, since the change would lead to reduction in weight The method included group discussions, intensive individual interviews and an experiment in which attempts were made to persuade some of the overweight women to adopt low-carbohydrate diets The results, though tentative, suggested that group sessions, and 'working through' the difficulties of dietary change in advance, might be useful for changing food habits

According to Colin Golby, a psychologist engaged in academic research is more concerned with analysing a problem than with its solution, conversely, in commercial research he is more concerned with finding the solution and often has to do this without an adequate analysis of the problems Describing "The Role of the Experimental Psychologist", he pointed out that the problem of inducing changes in food habits was but one example of the problem of persuasion It was necessary to appreciate the parts that different foods played This knowledge was useful as a basis of a persuasion campaign, which itself could well be modelled on the methods of product-testing used in commercial promotions The next step would be a search for a main appeal for the product Finally, there is much to be said for attempting the actual persuasion by the use of the 'theory of dissonance' This is based on the drive for consistency, and the conditioning of an agreement response With appropriate attention to technique, it might then be possible to carry a group through the four stages of persuasion, these are communication, conditioning agreement, attitude change and finally action.

Arnold Bender spoke on "The Nutritionist in Industry" Perhaps 98 per cent of the food we eat passes through the hands of the food processor, who consequently has considerable responsibility for our nutritional health It is certainly true that the public will buy and eat what it likes, but the food manufacturer can sometimes mitigate the harm of nutritionally inferior choice as, for example, in the fortification of white bread with minerals and vitamins In the opposite direction, there is no point in nutritionally desirable food being made without adequate attention to attractiveness Yet there are examples of food preparations which are sold in vast quantities, on the basis of quite unsubstantiated nutritional claims While this is less true in Britain than in the United States, we too can be persuaded into buying and consuming such useless commodities as cider vinegar or royal jelly, and especially into buying preparations for slimming In spite of this, we do not know whether or to what extent even genuine nutritional claims—high protein, or the presence of vitamins—influences consumption of particular foods Nor is it usually possible to forecast whether a new manufactured food will or will not be a commercial success, and in particular to forecast whether the success will be sufficient, as with breakfast cereals, to induce a major change in food habits

The final paper, "The Food Manufacturer in a World of Economic Reality", was presented by Edgar Graham From the commercial point of view, the food market has two desirable qualities continuous demand and inherent growth It has, however, also to contend with the conservatism of the consumer The manufacturer must nevertheless be concerned with inducing change, either for improving nutrition in the developing countries, or in taking account of changing social attitudes in the wealthier countries In the former, as well as in the latter, change can be successfully introduced only when commercial principles are used It is true that these may sometimes be misused, but without their use the most desirable change may be difficult or impossible to produce. On the other hand, the use of commercial principles will not be able to produce a change in food habits unless they are in the direction of both general nutritional opinion, and of changing social and cultural patterns. In order that a new food should 'sell', it must be readily available to the housewife at a time when she is in the mood to buy it, and there should be adequate communication to her of the reasons why she should buy it In spite of these general statements, there are, however, still great areas of ignorance where much more research is needed before we can be certain of success

The discussion through the day was intense and varied, but two or three major points emerged One was that, from the point of view of the nutritionist, the difficulty was how to make one's food wants coincide with one's food needs It appeared to be accepted by most people that what they like to eat must be what they need—that "a little of what you fancy does you good" This perhaps explained the lack of interest in nutrition education, even among those who were in general interested in health education Though many suggestions were made as to the value of different methods in changing food habits, it was agreed that we are in fact not very knowledgeable, and that much more fundamental research needs to be done

There was also general agreement that the meeting was an extremely useful beginning, in particular in bringing together the academic and the commercial interests in this problem The papers, with an introduction and a summary, will be published by MacGibbon and Kee early next year, under the title of "Changing Food Habits"

THE YARD UNIT OF LENGTH

By P. H. BIGG and PAMELA ANDERTON

National Physical Laboratory, Teddington, Middlesex

THE Weights and Measures Act, 1963, passed by Parliament on July 31, 1963, lays down that the yard shall be 0.9144 metre exactly, the definition will come into force on January 31, 1964.

As the National Physical Laboratory is to be called on to state the current values of the former Parliamentary yard standards in terms of the metre in connexion with the adoption of the new definition, they have once again been determined. At this juncture, when the material yard standards are ceasing to have their former significance, it is appropriate to sketch briefly the history of the yard standard as a background to setting on record the recent comparisons and their outcome.

The British measures of length are thought to have been derived initially from a very ancient and widespread measure known as the 'northern cubit', rather more than 2 ft. long, which can be traced back to Mesopotamia and Egypt. The half cubit, or foot, was recognized in 12 B.C. as a standard for land measurement in Lower Germany, and its length was recorded by the Romans. With the coming of the Saxons in A.D. 410 the foot became established in England. William I in 1066, succeeding sovereigns and Magna Carta in 1215, maintained the existing measures and weights. Edward I in 1305 ordained that "three grains of barley, dry and round, make an inch, twelve inches make one foot, three feet make an ulna . . ."[1], etc.* His original 'iron ulna' or 'ell', later called the yard, has long since disappeared, but from a study of various bronze yards still in existence it seems it is unlikely to have differed from our current yard by more than about 0.04 in. (1 part in 1,000). By present standards the primary standard of Henry VII (1497) is only 0.04 in. in error, while that of Elizabeth I (1588, standard until 1824) is correct to 0.01 in. Both these last-named standards are preserved in the Science Museum, London, with other historical yards.

The first scientifically constructed standards were commissioned in 1742 by the Royal Society. Two brass bars, 42 in. × 0.5 in. × 0.25 in., on which were engraved the lengths of the existing Tower Standard Yard (Rowley, 1720) and Elizabeth's 1588 yard were sent to the Academie Royale des Sciences and marked with the French half Toise of three Pied du Roi, one bar was retained in Paris and the other returned to the Royal Society, but both have been kept for reference.

A Royal Commission (1758–1760) under Lord Carysfort prepared a new bronze standard (the maker was Bird) 1 in. square in section with inset gold studs 36 in. apart, the yard being indicated by fine indentations. This standard bar became the legal primary standard in 1824, but it was ruined in 1834 when the Houses of Parliament were destroyed by fire, and was not replaced until 1855.

All but one of the present yard standards were designed, constructed and compared with existing standards by Sheepshanks and Bailey, acting as members of the Royal Commission of 1843–55 (ref. 2) and were legalized in 1855. They are bronze bars (copper 16, tin 2½, zinc 1) 1 in. square in section, cast by Troughton and Simms, London. At the bottom of a hole near each end of the bar is a small gold plug inserted with its flat surface approximately in the neutral plane of the bar. On each gold plug three fine lines 0.01 in. apart traverse the axis of the bar, and two lines 0.03 in. apart, parallel to the axis of the bar, intersect the three lines. The length defined by the bar is the distance at 62° F, under certain conditions of support of the bar, between the middle transverse line at one end and that at the other, the part of the line utilized being that between the longitudinal lines. One of the bars was selected as the Imperial Standard Yard and designated No. 1, and four others were regarded as copies, to be used for the replacement of the primary standard should it ever be lost or damaged. Copy No. 4 was immured in the Palace of Westminster and has rarely been disturbed. It is required that the copies should be intercompared every 10 years and compared with the Imperial Standard every 20 years, the immured copy being expressly exempted from these requirements.

The Weights and Measures Act, 1878, which was not superseded until this year, authorized the construction of a further copy (No. VI), which was brought into use by 1886.

It is convenient to turn now to the metre. When the metric system was set up at the end of the eighteenth century the metre was intended to be one ten-millionth part of a certain polar quadrant of the Earth, and the Mètre des Archives, a platinum bar, was constructed on this basis. It soon became clear that the basic definition was too inconvenient for practical purposes, so the Mètre des Archives came to be regarded as having primary status. In 1889 this standard was superseded by the International Prototype Metre, an X-section bar of platinum–iridium, the distance at 0° C between certain lines on the exposed neutral plane of which defined the metre without altering the length of the unit in relation to that defined by its predecessor. The prototype metre is at the head of a hierarchy of platinum–iridium metre standards, including the national copies, and the prototype and certain other important copies are preserved with every care at the Bureau International des Poids et Mesures at Sèvres, near Paris, under the auspices of the Metric Convention and the surveillance of successive General Conferences of Weights and Measures.

With the advent of the possibility of using wave-lengths of light for the measurement of length, first Michelson and Benoît and later other experimenters in various standards laboratories (including the National Physical Laboratory) determined the length of the metre in wave-lengths. Nine determinations were made during the period 1892–1940 (ref. 3) and the mean departure from the average result was only 1 part in 6 million, and there was no evidence of a secular change of length, it was therefore clear that the length of the prototype metre was extremely stable. Further, this and other research work at the National Physical Laboratory and elsewhere proved beyond doubt that progress in length measurement would best be served by re-defining the metre in terms of wave-lengths of light. Consequently in October 1960 the value 1 650 763·73 wave-lengths in vacuum of monochromatic orange light radiated by the krypton-86 atom was adopted for the definition.

Returning now to the yard, as a result of comparisons with the metre it was suspected by the National Physical Laboratory as long ago as 1932 that the Imperial Standard was not stable and in consequence the value then found was not put into effect for purposes of science and technology. The results of the 1947 comparisons[4] confirmed these suspicions, it was clear that there had been a fairly uniform shortening of the Imperial Standard during this century the total decrease in this period being nearly 2

---

* Further details may be found in "The English Yard and Pound Weight", by F. G. Skinner, *Bull. British Soc. Hist. Sci.*, 1 (May 1952), from which this historical information is taken.

Pergamon Press BOOKS

Handbook of Counseling Techniques

edited by E Harms, *New York*
Associate Editor P SCHREIBER, *Department of Social Work, Hunter College, New York*

The first handbook at the professional level to give a complete survey of the various types of counseling in the field of human relations The thirty six contributions are grouped under the topics Children and Youth, Family and Community; Employment and Vocation; Religions, Special Problems Essential reading for all engaged in counseling

516 *pages* 84*s net* ($12 00)

Psychopharmacological Methods

edited by Z Votava, M Horvath *and* O Vinai, *Prague*

Contains the Proceedings of a Symposium, held in Prague, on the effects of psychotropic drugs on higher nervous activity The book is in three sections covering the methodology in pharmacological research of the psychotropic drugs, different techniques for the evaluation of behavioural effects of psychotropic drugs in animal studies and problems of the clinical evaluation of effects of psychotropic drugs and possibilities of conditioned methods to help in clinical trials

390 *pages* £5 *net* ($14 00)

Handbook of Cosmetic Science

An Introduction to Principles and Applications

edited by H W Hibbott

This important handbook provides an up-to-date account of scientific principles and their application to the production of cosmetics The twenty-four articles include Skin physiology as a basis for cosmetic practice, Physiology of the teeth, Perfumery and its raw materials, Cosmetic colours; The chemistry and physical chemistry of surface active agents, Cosmetic emulsions, Microbiology; Formulation of oral hygiene products; Perfume formulation and product perfuming, Use of antiseptics and germicides in toilet preparations, Testing and evaluation of cosmetics

568 *pages* £5 *net* ($14 00)

An Introduction to Mathematical Analysis

by R A Rankin, *Professor of Mathematics, University of Glasgow*

Intended primarily for University students taking honours courses and beginning their first rigorous course in analysis, this outstanding textbook deals with the functions of a single real variable Topics discussed include limits and continuity, differentiability, integration, convergence and uniformity, infinite series, double series and infinite products Numerous exercises are given at the end of nearly every section and illustrative examples are worked out in the text

International Series of Monographs on Pure and Applied Mathematics, Volume 8

624 *pages* 80*s net* ($10 50)

Adaptive Control Systems

edited by F P Caruthers *and* H Levenstein, *Institute of Radio Engineers, New York*

Containing the proceedings of a symposium held at Long Island, this volume reviews progress in the field of adaptive control It deals with the concept of adaptiveness in a control system, going deeply into the actual definition of 'adaptiveness', and also gives information on those mathematical and experimental techniques which have proved valuable in understanding and developing these systems

The Proteins

Composition, Structure, and Function

(Second Edition)

Edited by HANS NEURATH

Volume 1, December 1963, about 600 pp, 157s 6d

***Subscription price, 139s. 6d**

**Subscription price valid on orders for the complete set received before publication of the last volume*

Volumes 3-4, in preparation

Reviews of the first edition:

"The prime virtue of this invaluable series will appeal to the expert and the beginner in proteins it presents a unified, critical, authoritative, and up-to-date treatment of the whole subject" —*Science*

"Considered together these four volumes will be referred to for many years, not only for all phases of the chemistry of these important macromolecules, but also for their biological properties and biological activities" —*Journal of Chemical Education*

Volume 2, about 675 pp, in preparation

Contents of Volume 1

Albert Light and **Emil L Smith,** Amino Acid Analysis of Peptides and Proteins **G. R. Tristram** and **R. H. Smith,** Amino Acid Composition of Certain Proteins **Klaus Hofmann** and **Panayotis G. Katsoyannis,** Synthesis and Function of Peptides of Biological Interest **Joseph S. Fruton,** Chemical Aspects of Protein Synthesis **Robert E. Canfield** and **Christian B Anfinsen,** Concepts and Experimental Approaches in the Determination of the Primary Structure of Proteins **R. Cecil,** Intramolecular Bonds in Proteins I The Role of Sulfur in Proteins **Harold A. Scheraga.** II Noncovalent Bonds

AUTHOR INDEX—SUBJECT INDEX

The Liver

Morphology, Biochemistry, Physiology

Edited by **Ch. Rouiller** In 2 volumes

Volume 1, December 1963, 683 pp, approx 186s

The Liver is intended to offer in a comprehensive form the present state of our knowledge of this organ based on morphological, biochemical, and physiological studies The correlation of structural, functional, and biochemical aspects is emphasized, and the latest results of modern methods of investigation are discussed

Primary Processes of Photosynthesis

By **Martin D. Kamen**

Volume 1 of **Advanced Biochemistry**· A Series of Monographs

Edited by Anthony San Pietro

December 1963, 182 pp, 44s.

This unique work explains the rationales of modern researches into the primary processes of photosynthesis which terminate before the onset of biochemical and physiological phases The bases for physical and photochemical investigations on the photosynthetic apparatus are presented and illustrated by examples from recent literature

Craigie's Neuroanatomy of the Rat

Revised and expanded by **Wolfgang Zeman** and **James Robert Maitland Innes**

November 1963, 230 pp, 68s

Long out of print, unavailable in the classroom, *An Introduction to the Finer Anatomy of the Central Nervous System Based upon that of the Albino Rat* is now published as a completely updated work tailored specifically for the student and research worker It is a classic treatment of the anatomy of the rat's central nervous system and its coverings, a study that also includes general principles of mammalian comparative neuroanatomy with ontogenetic and phylogenetic aspects

Atherosclerosis and Its Origin

Edited by **Maurice Sandler** and **Geoffrey H Bourne**

December 1963, about 550 pp, approx 157s 6d

This work covers the field of atherosclerosis focusing on human lesion Included are discussions of the roles of grand substance, hemodynamics, serum lipids, diet, hormones, and intrinsic metabolism of the arterial wall in the development of lesion.

The Soybean

Genetics, Breeding, Physiology, Nutrition, Management

Edited by **A. G. Norman**

Chapters in this volume were originally published in **Advances in Agronomy** and have been revised to bring them up to date.

November 1963, 240 pp, 52s

An authoritative account of the characteristics of the soybean plant and the production of soybeans, this work provides comprehensive review articles on every aspect of the subject Of special interest are the discussions of genetics and genetic principles in the breeding and improvement of the crop

Generic Names of Orchids

Their Origin and Meaning

By **Richard Evans Schultes** and **Arthur Stanley Pease**

With **"A Note to Orchidists"** by **Gordon W. Dillon**

December 1963, 331 pp, 86s

The dictionary explains the etymological history of the 1,250 generic names of Orchidaceae and the morphological or other characteristic of each plant that led to the choice of its generic name The original Greek or Latin components of the names are also given, along with the geographic distribution and tribal or subtribal classification of the genus shown together with the place of first publication of the epithet

parts per million This lent powerful support to those who wished to unify the British and American yards (the latter had been linked to the metre in 1893), and in 1959 it was decided by the national standards laboratories in the English-speaking world to adopt the definition 1 yard = 0 9144 metre for scientific and technological purposes This definition is now legal in the United States and Canada, and will shortly be so in all the countries of the Commonwealth, the exigencies of legislation had delayed legal action in Britain, but, as already stated, the Weights and Measures Act, 1963, received the Royal Assent in July 1963 and the provision that the yard shall become 0 9144 metre will come into force on January 31, 1964 An outcome of this Act and the re-definition of the metre is that the yard is now related precisely to wave-lengths of a standard radiation

The National Physical Laboratory was in a position to apply the new definition of the yard as soon as need be, indeed, for science and technology it had been using this definition since 1959 But because it is to be called on to pronounce on the present value of the former Imperial Standard Yard (now to be called the United Kingdom primary standard of the yard and referred to here as the Yard No 1) and its copies in terms of the yard unit equal to 0 9144 metre, and for reasons of history, it was decided to re-compare these standards and to assess all of them directly in terms of the metre so that the results could be held in readiness

Through the courtesy of the Standard Weights and Measures Department of the Board of Trade the various yard standards were made available to the Laboratory, which already has the custody of the national copy (No 16) of the former international metre The yard standards were intercompared in the National Physical Laboratory Standards Division transverse comparator following the methods described in the Board of Trade Reports 1950 (ref 4) and 1957 (ref 5) Included in the comparisons was a nickel transfer standard No 184, bearing both yard and metre intervals related so as to facilitate linkage with the metre[6]. This same nickel standard was then compared with the national metre No 16 and a number of National Physical Laboratory working standard metres which it was convenient to include in order to ascertain their present values The value of the metre No 16 was known both on the basis of comparisons with other metre standards at the Bureau International des Poids et Mesures and through direct determinations in wave-lengths of krypton-86 at the National Research Council, Canada[7] It was, therefore, possible to assess the present values of the yard standards in terms of the metre on both bases and to add a further point to the graph relating the Yard No 1 and the metre The results in Table 1 have been obtained in terms of the international metre defined in wave-lengths in 1960 and the 1963 yard equal to 0 9144 metre

Table 1

Values of the national yard standards in May 1963, in terms of wave-length international metre and the 1963 yard

Yard standard	Value at 62° F (16 667° C)	
	Metre	Deficiency in relation to the 1963 yard
No 1	0 914 396 9	0 000 12 in
No 2	0 914 396 2	0 000 15
No 3	0 914 395 1	0 000 19
No 5	0 914 395 9	0 000 16
No VI	0 914 389 8	0 000 40

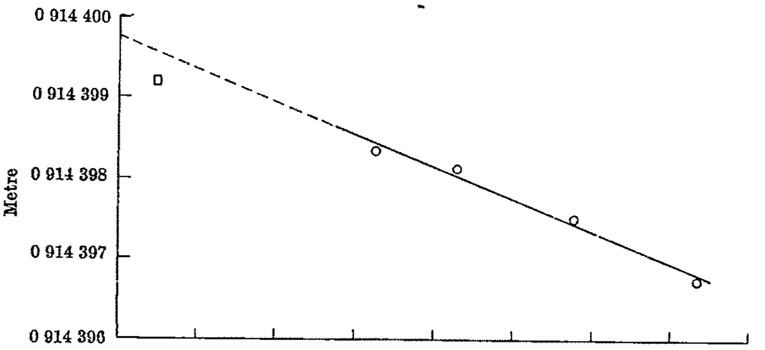

Fig 1 Values of Yard No 1 in terms of the metre as defined in 1889

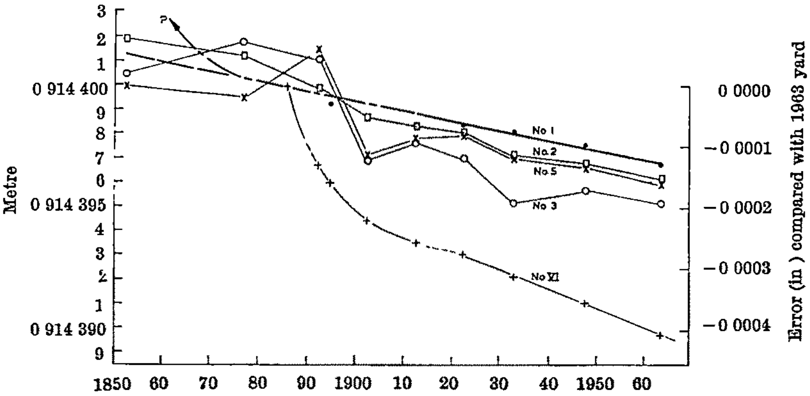

Fig 2 The yards in terms of the former International Prototype Metre and the 1963 yard Basis 1963–1922, yards compared with metre No 16 (via National Physical Laboratory Standard 184) 1922–1852, extrapolation of Yard No 1 and comparisons between yards

Fig 1 gives values of Yard No 1 since the turn of the century For consistency these values are based on the values of metre No 16 derived from the international prototype metre (used before the wave-length definition was adopted) The 1895 value was obtained at the Bureau International des Poids et Mesures by comparing Yard No VI and another yard (No 12) in all combinations with two subdivided metre standards, the comparisons being carried out by means of calibrated micrometer eyepiece microscopes, Yard No 12 had previously been compared with Yard No VI which itself was known in terms of the Imperial Standard.

The method used was not comparable with that later adopted, and though the result helped in 1948 to establish for the first time the instability of the yard system it is regarded as too old in relation to the present behaviour of the yard and too uncertain in relation to recent results to warrant its being given much weight now The line in Fig 1, which is accordingly based on the values found over the past 40 years only, shows that the Yard No 1 has decreased in length at the rate of 1 part per million in twenty-three years, corresponding closely to 0 0001 in so far this century

Fig 2 includes the information in Fig 1 on a reduced scale and shows the corresponding values for the other standards. Prior to 1922 no comparison of equal reliability exists, so the 1963/22 line has been extrapolated backwards, and this extrapolation, together with the observed errors of the copy yards in relation to Yard No 1, yielded the plotted values for this period

It may first be noticed that on this basis the value of Yard No 1 was exactly 0 9144 metre, that is, the 1963 legal yard, in 1884 The new definition of the yard therefore lays down a value equal to that defined by the Imperial Standard Yard in the early days of modern metrology Secondly, while at first sight it is curious that the values for Yard No 1 lie much more closely on a straight line than do those for the standards 2, 3 and 5 this is probably due to the slightly better quality of the fiducial lines on this standard This supposition is supported by the results for Yard No VI, on which the lines are perhaps a little better still, and for which over the period 1922–63 consistency of behaviour in the region of about 0 1 µm, or about 1 part in 10 million, has been experienced

The early history of Yard No. VI is one of rapid shortening. This standard was initially in extremely close agreement with Yard No. 1, but it is now 7 µm (about 2 5 ten-thousandths of an inch) shorter than No 1 and 10 µm (0 0004 in) shorter than originally. But for a slight discontinuity between 1912 and 1922 (due perhaps to a minor shock) it might have been even shorter now

The results on Yards 2, 3 and 5 have been much more irregular Those for Yard No 3 are particularly erratic, and it is interesting that this standard has been kept with the Pound No 2 which has also been a little unstable[4] Both the Yards 3 and 5 changed considerably in relation to Yard No 1 between 1892 and 1902 Incidentally, while Yard No 1 may have decreased similarly to No VI (Fig 2) in its early days, the spread of the values at any given time would be unaffected if this were allowed for. Broadly, Fig 2 shows that Yard No 2 has agreed with Yard No 1 very closely throughout their existence

In this article the present values of the yard standards, formerly the Imperial Standard Yard and its Parliamentary copies, have been presented against the background of an indication of the history of the yard from its earliest days to the present time Details of the recent determinations will be published shortly elsewhere It is a far cry from grains of barley to wave-lengths of a particular kind of light as emitted under closely defined conditions, whereas the earliest yard standards were probably not consistent to better than 1 part in 1,000 the present definition of the yard admits of a precision, through wave-lengths, of 1 part in 10^8 (ref 8) The present definition is likely to meet the requirements for accurate measurements for a long time to come For how long, it would be rash to hazard.

OBITUARIES

Dr. Graham P. DuShane

GRAHAM PHILLIPS DUSHANE, editor of *Science* during 1956–62, died of a heart attack on July 19, 1963 Earlier in the spring he had been in hospital for five weeks recuperating from a mild coronary attack Recovery was apparently thoroughly satisfactory, the intervening period had been one of partial rest and gradual resumption of his duties, at the time of his death he was on a leisurely trip from his home in Nashville, Tennessee, to Palo Alto, California The fatal attack thus came as an unexpected shock to family and friends and brought to an untimely end DuShane's career as experimental embryologist, teacher, editor and university administrator

Graham DuShane was born in South Bend, Indiana, on July 20, 1910, son of Donald and Harriette Graham (McLelland) DuShane He received the Bachelor of Arts Degree from Wabash College in 1930, which awarded him an honorary LL D degree in 1958 From Wabash College he went to Yale University to become a student under Prof. Ross Harrison, through whose guidance he received the Ph D degree in 1934 The summer of 1931 was spent in Munich and the year 1934–35 as a research associate at the University of Iowa Receipt of one of the highly coveted National Research Council fellowships allowed him to spend the following year at Stanford University During 1936–46 as instructor, assistant professor and then associate professor of biology in the University of Chicago he continued his research in experimental embryology of the amphibians, the development of pigmentation and the nervous system, and the induction of melanin by strange ectoderms His most significant research contribution was the finding in amphibians that cells migrate outward from the developing neural tube to become pigment cells in the ectoderm.

At the University of Chicago he also developed a reputation as an outstandingly good teacher, and was honoured by the University in 1945 with an award for excellence in undergraduate teaching In 1946 he accepted a professorship at Stanford University, where his research interests were primarily carried out by graduate students, while his own time was largely devoted to developing and supervising the excellent general biology course which was taken by most Stanford undergraduates and to the revision of the undergraduate curriculum in biology that he left as a legacy to Stanford when he became editor of *Science*

At the beginning of 1956 he joined the staff of the American Association for the Advancement of Science as editor of *Science* and *The Scientific Monthly* The six and a half years of his editorship were years of steady and major improvement in the quality, size and circulation of *Science* The merger of *The Scientific Monthly* with *Science* at the beginning of 1958 allowed DuShane and his editorial staff to concentrate on the one journal During this period he instituted the series of articles entitled "Current Problems in Research", each of which summarized for a general scientific audience the current state of an active field of research Started also as an important addition to *Science* was the section entitled "News and Comment", which quickly became the most widely read and useful source of information for scientists about governmental, economic and social actions and forces influencing scientific activities Under DuShane's editorship, the circulation of *Science* grew from 32,000 to 76,000

During his years as editor, DuShane received a number of invitations to return to a university post In 1962 one came that he decided he could not decline Vanderbilt University offered him the triple responsibility of a professorship of biology, chairmanship of the biology department and, in the newly created post of Dean of the Graduate Sciences, responsibility for graduate research and education in the basic sciences, medicine and engineering

He was a member of the American Association for the Advancement of Science, the American Society of Zoologists, the American Association of Anatomists, Sigma Xi, and Phi Beta Kappa He was a consultant to the President's Science Advisory Committee and a member of the Board of Trustees of *Biological Abstracts* At Stanford he served as president of the local chapters of Sigma Xi and the American Association of University Professors He is survived by his wife, Susan Elizabeth (White) DuShane, three daughters, and two brothers

DAEL WOLFLE

Dr Don E. Eyles

DR DON E EYLES died on October 4, 1963, of coronary thrombosis on board ship in Penang, Malaysia, a few hours before he and his family were due to return to the United States This sudden death of an outstanding scientist and excellent colleague was particularly tragic, as Dr Eyles was about to retire after twenty-four years' work for the U S Public Health Service to join the Lahore (Pakistan) Unit of the Institute of International Medicine of the University of Maryland School of Medicine

Dr Eyles was born in 1915 in Atlanta, Georgia, and obtained his M S (Biology) at Emory University and his Sc D at the Johns Hopkins University in Baltimore

During the early period of his academic life he was interested in ornithology and medical entomology, but later much of his work was connected with investigations on malaria imported into the United States by returning Service-men, and with curative action of drugs against relapsing malaria infections The difference between the effect of pyrimethamine and primaquine on the tissue forms of malaria parasites became clear as a result of this work The curative action of pyrimethamine and sulphadiazine, and the synergistic effect of these drugs in toxoplasmosis, were reported by Eyles *et al* in 1952, and these findings were promptly confirmed in acute and chronic forms of the disease Much knowledge of the epidemiology of toxoplasmosis was due to the work of Eyles on the relationship between the infection in domestic animals and its transmission to man

In 1960 Dr Eyles, taking a clue from his accidental laboratory infection, showed that *Plasmodium cynomolgi bastianellii* of monkeys can be transmitted to man through a mosquito This started much new and still expanding research on the possibility of simian malaria as an anthropozoonosis

In 1961 Dr Eyles was given the task of establishing a research unit of the U S Public Health Service in Malaya and he went to the Far East accompanied by his wife and three children The research unit was set up at the Institute for Medical Research in Kuala Lumpur and within less than three years Eyles and his Malaysian, American, British and Australian colleagues produced a remarkable series of investigations which have greatly extended our knowledge of simian malaria Five new species of malaria parasites of Malaysian monkeys and of a moose-deer were discovered and their relationship to a number of anopheline vectors was established

A new area for further research of considerable fundamental and practical importance was thus opened in a field that until recently seemed to be uninspiring and well-trodden The impetus given in this way to the investigation of simian malaria was characteristic of Eyles's vision, determination, leadership and phenomenal energy During the past year Eyles was greatly interested in the problem of resistance of human plasmodia to synthetic drugs and particularly 4-aminoquinolines He left a number of papers which are now awaiting publication

Some of us who saw Eyles in September at the International Congresses of Tropical Medicine in Rio de Janeiro and who heard his summary of the work carried out in Malaya could not help saying that he seemed to be in a hurry to complete one job to start another He was in a hurry, indeed, for his "appointment in Penang"

Eyles's work resulted in more than a hundred publications He has demonstrated his qualities as an administrator of a research laboratory and his brilliance and versatility as an investigator of general and specific problems in parasitology One of Eyles's most important assets was his ability to work with a team, he has undoubtedly stimulated in others as much research as he has been personally responsible for His proficiency in experimental work in parasitology was equalled by his general knowledge of ornithology, botany and entomology He was an intensely live individual—an inveterate collector of almost anything, biological or otherwise—universally liked and admired by those who have had the good fortune to know him during his short, happy and fruitful life

L J. BRUCE-CHWATT

Mr. Douglas P. R. Petrie

DOUGLAS PETRIE died at his home suddenly on October 13, aged fifty-two He was born in Australia, graduated in Melbourne in 1931 in physics, took his M Sc under the late Prof Laby two years later, having worked on X-ray vacuum spectroscopy and on this gained an 1851 Exhibition Overseas Scholarship which he held in the Cavendish Laboratory Here he worked with Dr M L E (now Sir Mark) Oliphant, developing the electron optics for a hydrogen ion gun and for a very high voltage discharge tube, one of the first essays in electrostatic focusing to be performed on ion accelerators He was awarded the M Sc for this work

In October 1937, he joined the research staff of the Valve Department of Standard Telephones and Cables, Ltd Like most of this staff, he was soon brought into the development of decimetre- and centimetre-wave oscillators for airborne radar sets and worked on this throughout the War Petrie's great physical and mathematical skill played an extremely important part in the development of practical continuous-wave oscillators for various wave-lengths from 6–20 cm which were used for a variety of operational and instrumental purposes The development of these required much detailed calculation of the distribution of high-frequency electric fields He discovered and proved a new theorem in electrostatics, which made it possible to replace intelligent guessing by accurate quantitative design

Little of his war-time work could be published at the time it was performed, but at the end of the War he collaborated with other members of the team to write a major paper on the principles of velocity-modulation which received the Institution of Electrical Engineers Radio Section premium award for 1946–47

After the War he joined the Associated Electrical Industries Research Laboratory as a section leader, jointly with Dr D R Chick, to develop the Company's interests in nuclear physics, and together they were responsible for designing and constructing a 4-MeV electrostatic generator operating under high gas pressure, it being the Company's intention to exploit the patents of Dr van de Graaff in Great Britain under licence The construction and use of the machine served to train the first generation of scientists in Associated Electrical Industries for the coming nuclear power developments, but in addition very many new ideas were incorporated into this machine, in particular, Petrie's experience of ion focusing Before the idea of tandem generators had been developed, Petrie and Dr Chick in 1948 began the investigation of a helical slow-wave structure to accelerate ions emerging from the van de Graaff generator then being built, and, with others, he designed and constructed a pilot length of 1 metre, into which 2 5-MeV protons were injected and accelerated successfully to 4 MeV This would certainly have been continued but for the proved success of the tandem generator, the first of which to be built by the Associated Electrical Industries incorporated a number of significant improvements due to Petrie

Petrie then turned to electron optics and took charge of the Section dealing with this subject He developed the lens designs for a one-million-volt electron microscope which might have given a resolving power of 1–2 Å and worked out the theories of quadruple and octuple systems for correcting spherical aberration, he set up an experimental electron-optical bench for the measurement and correction of spherical aberration and devised computer programmes to solve related problems His great mathematical ability coupled with a keen physical insight kept his work in the forefront of what was required by the industry, and he keenly wanted to join the engineering team responsible for instruments based on electron optics

He was of a quiet disposition, and thought deeply before he spoke, his pronouncements were always appreciated by his colleagues and staff In earlier life he had composed music which had been played in public, and he was a good tennis player

He leaves a widow and one son

T E ALLIBONE

NEWS and VIEWS

The Royal Society Awards: Royal Medals

H M THE QUEEN has approved recommendations made by the Council of the Royal Society for the award of the two Royal Medals for 1963 as follows to Prof H H Read, emeritus professor of geology in the University of London and Senior Research Fellow in geology, Imperial College of Science and Technology, London, for his outstanding contributions to the understanding of the processes of rock metamorphism and the origins of granite, to Dr Robert Hill, member of the staff of the Agricultural Research Council, for his distinguished work in the biochemistry of plants, especially for his contributions to knowledge of photosynthesis

Mathematics in the University of Warwick:

Dr E C. Zeeman

DR E C ZEEMAN, whose appointment to the chair of mathematics in the new University of Warwick has recently been announced, has, since the War, been one of the leaders of the school of topology in Cambridge, where he is a University lecturer in mathematics and a Fellow of Gonville and Caius College His work has been mainly in the geometrical theory of manifolds and he has taken a leading part in the recent revival of purely combinatorial methods in this subject He had a large share in the work which led to the proof two years ago of the Poincaré hypothesis for spaces of dimension 5 and upward, a famous conjecture which had been outstanding for many years in spite of many attempts on it He has also recently put forward an interesting theory of the functioning of the brain, and especially of the processes of vision, based on concepts taken from those of general topology Dr Zeeman's loss is bound to be keenly felt in Cambridge, where he is the centre of an active research group He will have the good wishes of all for his success in building a new school at Warwick

Inorganic Chemistry at Monash University:

Prof B. O West

DR B O. WEST has been appointed to the newly established chair of inorganic chemistry at Monash University Dr West, who was born in 1928, was educated at Adelaide Boys High School and the University of Adelaide After graduating with honours in physical and inorganic chemistry in 1949, he joined the staff of the Chemistry Department of the University of Adelaide, where he held the positions of demonstrator, lecturer and senior lecturer and was, in 1962, appointed reader in inorganic chemistry During this period, in 1953–54, he spent two years at the University of Cambridge, where he held a Rhondda research studentship at Gonville and Caius College, and worked in the inorganic chemistry research laboratories Dr West's main research interest has been in the chemistry of co-ordination compounds and he has made significant contributions to our knowledge of the preparation and reactions of the inner complexes More recently, he has also become interested in the chemistry of organometallic compounds and has developed new methods for the synthesis of compounds containing both fluoroalkyl and alkyl or aryl groupings attached to the same element

Bio-Engineering at the Royal College of Science and Technology, Glasgow

THE Council of the Royal College of Science and Technology has announced the formation of a Bio-Engineering Unit within the Department of Mechanical Engineering, Dr R M Kenedi has been appointed research professor, as from October 1, 1963 Work in this field first commenced in the Department of Mechanical Engineering in the College some six years ago with experimental studies of skin tension in the human body and with the application of refrigeration techniques in hypothermia Since then, the Department's research activity in this field has greatly intensified in close co-operation with Glasgow's teaching hospitals Co-operation takes the form of direct collaboration between surgeons, physicians and engineers, working as combined teams in the College engineering laboratories, the hospital wards and operating theatres and the various medical research departments as required Thus the medical side is allowed every opportunity to become familiar with the available relevant engineering techniques, while the engineers are taken directly into the hospitals to become fully acquainted with particular medical problems under consideration in relation to the human patient The Unit will be administered by the Department of Mechanical Engineering in the College in association with a Steering Committee The primary duty of the Steering Committee will be to screen the projects put forward for investigation and to authorize work on such as seem suitable and practicable.

Dr R M. Kenedi

DR R M KENEDI graduated B Sc with honours in civil engineering at the University of Glasgow in 1941, and was awarded the degree of Ph D (Glasgow) in 1947 He was awarded the honorary degree of C H of the National University of Engineering, Lima, Peru, in 1958, and is an Associate Member of the Institution of Mechanical Engineers and an Associate Fellow of the Royal Aeronautical Society He joined the staff of the College in the Department of Civil and Mechanical Engineering in 1941 and was appointed to a senior lectureship in 1947 He became reader in strength of materials in 1956, a post which he has held until his present appointment In addition to his academic duties, Dr Kenedi has pursued a wide range of research interests, many connected with industrial problems In 1957 he carried out a two-month tour of universities and industrial research centres in the United States, surveying current research on cold-forming processes and products for the Cold Rolled Sections Association, and in 1958, as a result of a joint invitation from the Universidad Nacional de Ingenieria, Lima, and the British Council, he spent some six weeks in Peru, lecturing and advising on the contents of engineering courses and on the planning of a materials testing laboratory Dr Kenedi was born in Hungary and became a naturalized British subject in 1947

Nuffield Unit of Medical Genetics at the University of Liverpool

The Trustees of the Nuffield Foundation are to make a grant of up to £350,000 to the University of Liverpool in support of the capital and running costs of a proposed Unit of Medical Genetics This Unit will be established under the ægis of the Department of Medicine It is anticipated that the grant from the Nuffield Foundation will meet the major part of the cost of the Unit for a period of nine years The University has undertaken to assume full responsibility for the Unit from the beginning of the academic year 1972–73 Since 1953 an increasing amount of work in human genetics has been carried out in Liverpool At the present time there are ten workers investigating human genetics problems in the Department of Medicine under Lord Cohen of Birkenhead The emphasis throughout has been on investigation into the causes of common diseases, among them duodenal ulcer, rheumatic fever, rheumatoid arthritis, Rh hæmolytic disease and its prevention, leukæmia and other cancers, thyroid disease and schizophrenia Dr C A Clarke, reader in medicine at the University, will direct the Unit of Medical Genetics, which will work in close association with Prof P M Sheppard, head of the Department of Genetics at Liverpool, with Prof E B Ford, of the University of Oxford, and with other universities

The Imperial College of Science and Technology and the Indian Institute of Technology (Delhi)

The Imperial College of Science and Technology, University of London, has entered into special relationship with the Indian Institute of Technology (Delhi), formerly the Delhi College of Engineering and recently raised by the Government of India to the status of an institute of national importance The British Government, in collaboration with British industry, has given substantial financial assistance towards the new Institute's full development Parallel academic assistance will be provided through the special relationship with the Imperial College This will be made possible through financial help from the Department of Technical Co-operation Discussions are now proceeding in London between Dr Thacker, chairman of the Board of Governors of the Indian Institute, Sir Patrick Linstead, rector of Imperial College, and Sir Willis Jackson, chairman of the British Technical Committee The scheme will involve long-term secondments of Imperial College staff, training of Indian staff at the College and short visits to Delhi by senior College staff Academic assistance is already in being for example, the chair of mechanical engineering at the Indian Institute has been filled for more than a year by Prof N P W Moore He is on long-term secondment from Imperial College, where he holds the post of reader in the Department of Mechanical Engineering

The Council of Scientific and Industrial Research, New Delhi. Publications

The present publications of the Council of Scientific and Industrial Research, New Delhi, include the *Journal of Scientific and Industrial Research*, a monthly general science periodical, replacing the *Journal of Scientific and Industrial Research Section A—General*, the *Indian Journal of Chemistry*, a monthly research periodical devoted to original communications in chemistry (including biochemistry), replacing the chemistry part of *Section B—Physical Sciences*, *Indian Journal of Pure and Applied Physics*, concerning original communications in physics, replacing the physics part of *Section B—Physical Sciences*, the *Indian Journal of Technology*, again a monthly research periodical dealing with applied sciences and technology, replacing *Section D—Technology*, and the *Indian Journal of Experimental Biology*, a quarterly research periodical embracing original communications of an experimental nature in the biological field, replacing *Section C—Biological Sciences* The *Indian Journal of Technology* (1, No 6, June 1963) gives details of the aforementioned changes and coverage of the subjects sponsored by the Council This particular issue is notable for the range of subjects discussed, including investigations on activators for vulcanization of rubber, oxidation of cellulose by chromic acid in presence of hydrated oxides of metals, modification of lac esterification of lac with allyl alcohol, investigations of stamped charging of coals for coking, utilization of lignite dust for making granular products, observations on the theaflavin gallate and thearubigins of black tea, chemical composition of mackerel (*Rastrelliger canugurta*) changes in the nutritive value during storage, dehydration of green peas These papers are followed by short communications traversing an equally versatile range of subjects

The British Glass Industry Research Association

The eighth annual report of the British Glass Industry Research Association presents brief accounts of seven major projects, largely carried out in what is clearly the closest co-operation with the industry itself (Pp 44 Sheffield The British Glass Industry Research Association, 1963) Among some highly interesting operational work is an inter-firm comparison of the performance of container furnaces, from which differences in British and American practice were brought into prominence American practice leans towards higher temperatures and higher melting rates, and it is interesting that of 142 American furnaces noted, none was now using producer gas, while a third of the 100-odd British furnaces were still on this fuel, although its use has fallen by a half in the past ten years Other operational exercises dealt with batch mixing and handling in the founding problem and with inspection and handling of glassware There are some interesting and unsolved problems in the loss of the strength during storage, a phenomenon which is also observed for some ceramic products Fundamental work on strength has continued with particular reference to the possible application of ion-diffusion techniques to conventional mass-produced glassware, and it has been demonstrated that ion-diffusion processes can increase the strength of abraded unetched samples from about 30,000 lb /in ^{2} to 90,000 lb /in ^{2} On the technological scale, stress configurations on large glass panels under uniform loading are being investigated by strain-gauge techniques Considerable progress has been made on the examination of heat transfer from glass through the mould, and the condensation aspect has been solved An analogue computer has been built to extend the investigation to take account of heat transfer by radiation The report concludes with a note on the information service and a list of reports and publications It is depressing to read that "the rising costs of running the Association have not been matched by any increase of income" and that a planned reduction of staff is contemplated One must deplore that a massive national asset like the family of research associations should have to see any of its members financially embarrassed

History of Science

Volume 2, 1963, of *History of Science*, an annual review of literature, research and teaching, is noteworthy for F Maddison's survey, with bibliography, of sources and modern studies of early astronomical and mathematical instruments, W A Smeaton's paper, "New Light on Lavoisier the Research of the Last Ten Years", and R E Schofield's article on the needs and opportunities for research into the histories of scientific societies Under the title "Merton Revisited", A R Hall contributes a critical re-examination of R K Merton's article in 1938 on science, technology and society in seventeenth-century England, while A H Ewen describes a sixth-form course in the history of the philosophy of science Among the ten essay reviews may be mentioned D T Whiteside's discussion of the scientific papers of Newton; R W. Southern on technology and history, and D S L Cardwell on science in the nineteenth century *History of Science* is edited by A C Crombie and M A Hoskin and published by W. Heffer and Sons, Ltd , Cambridge (paper bound, 21*s*. net, cloth bound, 30*s* net)

The Society for the Promotion of Nature Reserves

THE 1963 *Handbook* of the Society for the Promotion of Nature Reserves includes, besides the forty-ninth annual report covering the year ended March 31, 1963, and the accounts and balance sheet, a report on the Council for Nature, membership of which has risen to 339, and lists of the Society's reserves and local committees, officers and Council, Naturalists' Trusts and members and associates (Pp 44 London The Society for the Promotion of Nature Reserves, British Museum (Natural History), 1963 10*s*). Annexes to the report list purchases completed during the year with the aid of the Nuffield Loan Fund The report includes brief accounts of activities during the year on the Society's own reserves, and in that relating to Dancer's End, Buckinghamshire, reference is made to the pillage of wild flowers and the difficulty of restricting such pillage

African Engravings and Decorations

THE Museu do Dundo, run by the Portuguese Diamond Co of Angola (Diamang), has long been famous for its splendid publications concerned with the cultures, past and present, of the country The latest, *Cabaças Gravadas da Lunda*, by Mário Fontinha and Acácio Videira, is concerned with the engravings and decorations on calabashes, which are used to-day as drinking-vessels, mugs, funnels, boxes, etc (*Publicacoes Culturais* No 57 Pp 178 (34 plates) Lisboa Companhia de Diamantes de Angola, 1963) The engravings are made with a sharp knife, the blade being thick or thin according to the lesser or greater delicacy of the strokes to be made The volume is largely a picture book illustrating a considerable number of these engravings For the most part, conventionalized human beings are depicted, some of them very amusing to look at But animals, equally stylized, and patterns also occur One interesting figure represents a man driving a motor-car The economy of line would probably please many modern European artists For those interested in pre-historic and primitive art it is always well to take note of a modern art group made by modern primitive peoples This work can be strongly recommended, both for its scientific value and as an intriguing picture book.

Distance of the Andromeda Galaxy

THE late Dr W Baade was interested in extending our knowledge of the stellar populations and obtaining a more accurate distance of the Andromeda Galaxy. For this purpose he selected a number of fields at varying distances from the centre of the Galaxy and obtained a large number of photographs The results for one field have now been completed by his associate, Miss H H Swope (*Astronomical J* , 68, 435, 1963) They refer to a field 96′ south preceding the nucleus in a very distant outer spiral arm, selected for its low content of absorbing material More than 150 variable stars have been found, and. of these, twenty Cepheids have been investigated in detail, obtaining brightnesses and periods of variation The Andromeda cepheids are systematically reddened in comparison with those in our own Galaxy, but it is thought that this reddening arises mainly in our Galaxy and not in the Andromeda Galaxy The Cepheids are further from the centre of the Andromeda Galaxy than the Sun is from the centre of our own Galaxy The unreddened distance modulus turns out to be +24 20 magnitudes. The distance is 690 kiloparsecs (2 25 million light years) with an uncertainty of at least 50 kiloparsecs

Textile Research at the Lódz Technical University

THE theory of flow in the multi-branched siphon is developed in No 9 of the *Textile Sciences* (*Włókiennictwo*) series of the *Scientific Bulletin of the Lódz Technical University* (*Zeszyty Naukowe Politechniki Lódzkiej*) This siphon is the main feature of Prof Atanazy Boryniec's invention for spinning staple viscose fibres in a hydraulically closed system to which gases harmful to health may be confined Other papers deal with the role of sulphuric acid in the acetylation of cellulose; the use of melamine–urea–formaldehyde mixed precondensates for imparting crease recovery to linens and viscose–flax blends; benzylation of cellulose; stability of knots in fishing nets, structural changes in polyacrylonitrile fibres during drawing and heat treatment All papers are in Polish, but there are Russian and English summaries, which are sometimes extensive. The *Bulletin* is mimeographed and appears about once a year. It is edited by Dr Witold Żurek, and copies are obtainable from Redakcja Wydawnictw Naukowych Politechniki Łódzkiej, Łódź, Gdańska 155, Poland

New Coagulant Aids for Removal of Suspended Particles

FLOCCULANTS facilitating removal of suspended solids from sewage and industrial wastes, also in pre-treatment of raw water similarly charged, are now reinforced with what are described as " . new coagulant aids . liquid, water-miscible polyamines (cationic polyelectrolytes)" These products are known as 'Primofloc *C*-3' and 'Primofloc *C*-5' and are now being offered on a commercial scale by Rohm and Haas, Philadelphia, Pa , well known for their manufactures of plastics, synthetic resins and chemicals for many industrial applications A recent issue of the *Rohm and Haas Reporter* (21, No 3; May–June, 1963), a colourful and informative house-organ (distributed in Britain by Lennig Chemicals, Ltd , Bedford Row, London, W C 1), gives full details of these compounds, also of the many technical services offered in the wide field of their international activities

Treatment of Tuberculosis

BEFORE the advent of potent and anti-tuberculous drugs, the recovery of patients depended entirely on natural and acquired resistance augmented by supporting treatment This inevitably resulted in a high mortality With the use of anti-tuberculous drugs, especially streptomycin, isonicotinic acid hydrazide and para-aminosalicylic acid, the prognosis of this formerly deadly disease changed for the better The application of adrenocorticotrophic hormone or adrenal corticosteroids and their analogues achieved equally promising results When hormones were first used, reports were discouraging because the hormone was given alone or for the treatment of another disease without enough knowledge of the underlying tuberculous lesion To-day, combined treatment is increasingly used and often without knowledge of all the facts A communication by Drs Somchai Bovornkitti, Prasert Kangsadal, Pairojana Oonsombatti and Damrong Bejrablaya of the Departments of Medicine and Physiology, Faculty of Medicine, and Siriraj Hospital, University of Medical Sciences, Dhonburi, Thailand, reports their experience on the use of prednisone concurrently with conventional anti-tuberculous treatment in cases of tuberculous pleurisy with effusion (*Japanese Journal of Tuberculosis*, 10, No 1–2, June, 1962) Twenty-three cases of pleurisy with effusion, presumably tuberculous in origin, were treated with a combined régime of prednisone and conventional anti-tuberculous drugs Prednisone was used for a month The results indicate that the combined treatment is superior to the conventional anti-tuberculous remedies used alone The results of treatment were attributed to the desensitizing properties of prednisone on tuberculin hypersensitivity.

Visiting Fellowships in Astrophysics

APPLICATIONS are invited by the Joint Institute for Laboratory Astrophysics, Boulder, Colorado, for visiting fellowships in theoretical astrophysics, low-energy atomic physics and other closely related areas The fellowships, tenable for one year or possibly a shorter period, are awarded by the University of Colorado for the Institute, to provide an opportunity for persons actively contributing to these fields to visit the Institute to continue their studies and research in the field chosen by them The amount of the stipend will normally equal the recipient's present academic salary adjusted to a twelve-month basis The cost of transportation to and from Colorado for the recipient and his immediate family will also be met by the Institute The closing date for application is January 15 Further information and forms of application can be obtained from the Secretary for Visiting Fellows, Joint Institute for Laboratory Astrophysics, University of Colorado, Boulder

The Vernon Prize in Industrial Psychology and Physiology

THE late Dr H M Vernon made a bequest to the National Institute of Industrial Psychology expressing the wish that the Institute should award a prize every second year to the investigator who, being a British subject and under the age of forty-five years, has in the opinion of the Council of the Institute done most valuable research work in service of industrial psychology or industrial physiology The sixth award will be made in 1964, it will consist of approximately £40 in cash and a silver medal Recommendations are invited of the names of workers in this field whom the Council should consider Direct applications for the award may also be made Recommendations or applications, supported by reference to published work and, if possible, copies of unpublished but relevant reports, should be made to the Director, National Institute of Industrial Psychology, 14 Welbeck Street, London, W 1, by February 29, 1964

The David Anderson-Berry Prize

A DAVID ANDERSON-BERRY Silver-Gilt Medal, together with a sum of money amounting to not less than £100 (280 U S dollars), will be awarded by the Council of the Royal Society of Edinburgh during 1964 The Prize will be awarded for recent work on the effects of X-rays and other forms of radiation on living tissues Published work will be taken into consideration if submitted to the Society with the application In addition to direct application for the Prize, proposals can be made on behalf of others Applications and proposals must be sent to the General Secretary, Royal Society of Edinburgh, 22–24 George Street, Edinburgh 2, Scotland, by March 31, 1964.

Courses in Higher Technology

THE wide variety of courses in advanced technology and management studies available to students in the London area is again presented in a bulletin prepared by the London and Home Counties Regional Advisory Council for Technological Education (*Bulletin of Special Courses in Higher Technology, Management Studies and Commerce, 1963–64*. Part 1 Autumn Term Pp 134 London London and Home Counties Regional Advisory Council for Technological Education, 1963 4*s*) The courses range from elements of law relating to civil and mechanical engineering at Battersea College of Technology, hydraulic and electrical control of injection moulding machinery at the Borough Polytechnic, a practical course in Elliott 803 autocode at Brunel College, the economics of tanker operation (shipping) at the City of London College, the Lebesgue integral at Hatfield College of Technology, solar heat gain at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, gyrodynamics and inertial navigation at the Northampton College of Advanced Technology, rapid reading at Slough College, and carpet planning at the Technical College for the Furnishing Trades

Announcements

WE regret to announce the death on November 13 of Dr Margaret Murray at the age of 100 (*Nature*, 199, 119, 1963)

SIR WILLIAM PENNEY, deputy chairman of the United Kingdom Atomic Energy Authority, has been appointed to succeed Sir Roger Makins as chairman of the Atomic Energy Authority when he retires in February 1964 Sir Roger Makins was appointed chairman of the Authority in 1960 Sir William Penney has been a member of the Authority since it was set up in 1954

THE Plastics and Polymer Group has instituted an annual prize of £50 for the best paper submitted on any aspect of pure or applied polymer science The competition is open to all British subjects under thirty years of age Full details can be obtained from the Secretary, Plastics and Polymer Group, c/o Society of Chemical Industry, 14 Belgrave Square, London, S W.1.

THE Yearbook of the National Institute of Sciences of India, 1962, besides the report of the Council, to which are appended brief reports on research in physics, chemistry, botany, zoology and physiology, includes a brief account of the foundation of the Institute together with the lists of Fellows, membership of Council and committees, grants and publications and additions to the Library, as well as the rules and regulations (Pp vi + 251 New Delhi National Institute of Sciences of India, 1963 Rs 15 00)

THE 1963 Arthur Stanley Eddington Memorial Lecture entitled "Mind and Consciousness in Experimental Psychology" will be delivered by Dr R H Thouless in Cambridge on November 29 Further information can be obtained from W. B Harland, Arthur Stanley Eddington Memorial Trust, Gonville and Caius College, Cambridge

THE annual meeting of the American Association for the Advancement of Science will be held in Cleveland, Ohio, during December 26–30 Further information can be obtained from Mr Kneeland A Godfrey, American Association for the Advancement of Science, 1515 Massachusetts Avenue N W , Washington 5, D C

AN introductory course on "The Biology of the Skin" will be held in the School of Clinical Research and Postgraduate Medical Teaching, University of Cambridge, during December 9–14 The course is intended primarily for registrars and postgraduate students at an early stage of their training in dermatology, but is also open to other medical practitioners The fee for the course will be 5 guineas Further information and forms of registration can be obtained from the Secretary, Cambridge University Medical School, Tennis Court Road, Cambridge

THE forthcoming programme of the recently formed Society of Acoustic Technology (see *Nature*, 197, 23, 1963) will include a meeting on "Acoustics", arranged jointly with the Liverpool and North Wales Branch of the Institute of Physics and the Physical Society at the University of Liverpool (December 11), a meeting to discuss "Practical Cases of Noise Reduction" at Salford (January 16), a meeting on "Noise in Ventilation Systems" at Manchester (February 21), a meeting on "Scale Model Techniques" at Salford (April 15), a conference on "Planning and Design for Protection from Noise" at Coventry (June 1–4), a conference on "Medical and Industrial Aspects of Hearing Loss" at the University of St Andrews, Dundee (September 25–27) Further information can be obtained from Dr P Lord, Department of Pure and Applied Physics, Royal College of Advanced Technology, Salford.

THE GEOLOGICAL SOCIETY OF AMERICA, 1888-1963

ON December 28, 1888, the geologists of America, previously forming a group within the American Association for the Advancement of Science, started their own Society, the Geological Society of America, at a meeting in Ithaca The list of Founder Fellows numbered 109

Since that time the United States has progressed consistently in geological research, due mainly to its wealth in geological material The exploration of the West, with the palæontologists reporting on fossils, has led to important discoveries in the structure, the dynamics and the evolution of the vertebrates forming probably the most brilliant chapter in the earlier history of geology The invertebrates, though deprived of a solid structure, left enough imprints throughout the ages to allow the palæontologists to reconstruct a substantial part of their biological and evolutionary past The origin of life and of the Earth are other subjects closely associated with the aims of geology. Coal, ores, petroleum, light and rare metals, radioactive elements, all are the concern of geologists, who must also be credited for advances in prospecting methods, in the study of the ocean floors, of water resources, earthquakes, and in the techniques of surveying and mapping Geological engineering is a new development, and if man sets foot on a new planet, the chances are that this man will be a geologist

The Geological Society of America acts as the academic body, the guardian of the science of geology and related earth sciences Oceanography, seismology, astrogeology, the study of meteors, of the crust and the mantle of the Earth, the behaviour of rivers, wells, lakes, water resources, the construction of dams and tunnels, hydroelectric systems, location of mines, their development and prospecting, all need the helping hand of the expert geologist

The Society soon formed one of the best trained groups of geologists in the world, and its efforts united and encouraged them, and helped them to overcome their earlier provincialism Geology had come of age in the United States

Still, in the early 1930's this was a rather small society (600 members), until one of its Fellows and one-time president, a practising geologist, professor and investor, son of a prominent Philadelphia family which had been better known for its political connexions, bequeathed half his estate to the Society (the other half to the American Philosophical Society in Philadelphia) The benefactor was Dr Richard A F. Penrose, jun, who died on July 31, 1931, leaving to each society approximately 3,900,000 dollars, to be considered an endowment, the income of which was to be used and the capital to be properly invested Probably no other small organization devoted to a relatively humble science was ever before so lavishly endowed Although, in the succeeding years, the Society may have disbursed more than twice the value of the endowment, the capital fund still stands to-day in excess of the original valuation

In the years following this gift, geological science has witnessed an almost explosive evolution to which the bequest has not been foreign It revolutionized the Society, opened new vistas, supplied needed support, and raised the Earth sciences to their rightful place in scientific research About 40 per cent of the income went to publications, and a large share to grants in aid of research The journal of the Society, the *Geological Society of America Bulletin*, a primary objective created in 1890, changed from a quarterly to a bi-monthly and, in 1935, to a monthly It was the first publication in a position to add inserted charts and coloured maps to its text

But the *Bulletin* was not enough to provide an outlet for manuscripts, particularly those too long or unsuited to a journal From this need originated the more extended publishing programme of the Society, and the list of its *Memoirs* and *Special Papers* now numbers about two hundred These volumes, of permanent value, are considered essential tools for research in the Earth sciences

A *Bibliography and Index of Geology exclusive of North America* was authorized in 1932, of which 26 volumes have appeared so far, and in this series of annotated references the foreign geological literature is reported This effort parallels and complements that of the U S Geological Survey, which publishes the *Bibliography of North American Geology*

Another important enterprise is the publication of the *Treatise on Invertebrate Paleontology* in 24 volumes by 180 authors from all over the world 12 volumes have been completed and 12 are in process

Many geologists prefer accurate maps to descriptive texts For their benefit the Society has allocated funds for the production of large wall maps, compiled from many dispersed smaller ones Geological maps of North America, South America and Mexico, and glacial, tectonic, physiographic and ocean maps have been completed. This work continues

Some 1,000 individuals have been assisted in their investigations by grants in aid at an average of about 1,500 dollars a grant

The Penrose Medal (endowed as early as 1927) is the greatest honour bestowed by the Society and is highly prized among the awards to which geologists of the world are eligible

During November 18–20 the Geological Society celebrated its seventy-fifth anniversary when its meeting was held in New York (at the Hotel Commodore). The roster of Fellows, Members, students and guests attending, from the original 109, exceeded 3,000

The Geological Society of America has been fortunate in the continuity of its leadership Its seventy-five years of history have been witnessed by only seven secretaries and six treasurers The officers for 1963 are *President*, Harry H Hess, *Vice-President*, Francis Birch, *Secretary*, Joe Webb Peoples, *Treasurer*, J Edward Hoffmeister

At the time of convening in New York, the Society is leaving its stately home on the Columbia Campus, where for thirty years the welcome mat was out for visiting geologists The mat will be moved to 231 East 46 Street, the new building acquired this year by the Society

---

DURING the seventy-fifth anniversary meeting, three general symposia were held (1) Relation of Geology and Trace Elements to Nutritional Problems, (2) Geology of Ocean Basins and Continental Drift, (3) The Principle of Uniformity

Awards and medals were presented, namely the Kirk Bryan Memorial Award, to Arthur H. Lachenbruch (U S. Geological Survey), the Penrose Medal, to William W

Rubey, University of California, Los Angeles, the Arthur L Day Medal, to Keith E Bullen, University of Sydney Associated societies took part in the celebrations, namely, the Mineralogical Society of America, the Paleontological Society, the Society of Economic Geologists, the Geochemical Society and the National Association of Geology Teachers Some of these societies also presented awards at the meeting

PREPARATION AND PUBLICATION OF GEOLOGICAL JOURNALS

A TWO-DAY meeting of editors of British geological journals, sponsored by Messrs Oliver and Boyd, Ltd, was held in Edinburgh during October 11–12 The meeting covered a wide range of topics including instructions to authors, refereeing, preparation of manuscript for printer, relations with printer, design and layout of British geological journals, blockmaking, sales, distribution and costs, index cards

Suggestions as to ways of reducing editorial chores were few. The solution seems to rest largely with the author and the better preparation of his script The *World List* reference style has been adopted by most geological journals in the past few years, but inconsistency in references still remains an editorial problem More uniformity in instructions to authors was welcomed by some, but not all, of the editors present It was understood that the Geological Society of London's detailed notes to authors are due to be revised, and the hope was expressed that much of the material in the new edition would prove to be of general use Certainly the plea for a more uniform treatment and a higher standard of diagrams was welcomed by those present

Mr Thomson (Oliver and Boyd) discussed editorial relationships with the printer A clean copy, as always, is much to be preferred Once the printer knows a journal style, only a small amount of mark-up, such as the centring of headings and indenting, is required He revealed that printers generally keep notes of the style of each journal, including the spelling of scientific words peculiar to that journal, and that uniformity of style from issue to issue is achieved by using the same compositor.

It was agreed that authors did not appreciate the high costs involved in even minor alterations (as was proved by a visit to the compositors' room), and all the editors welcomed the opportunity of acquiring copies of *Authors' Alterations Cost Money and Delay*, produced by the British Federation of Master Printers This pamphlet would be sent out to authors at the proof stage. The suggestion was made that authors should be charged for all alterations, printer's errors apart, that they made to the proofs The advantages of this scheme lie in the saving in costs and in quicker publication since it might be possible to omit the galley proofs and go straight into page proof The disadvantage lies in a less-than-perfect final copy in which the errata are confined to a short appendix

Mr Ian Wilson, chairman of the Scottish Council of Industrial Design, provided one of the highlights of the meeting by making a candid assessment of the design and layout of British geological journals He classified them into three groups, 'Pleasing', 'Nothing special but some care shown', and thirdly, 'Nothing done since first published' It would be invidious to classify them here, but several general criticisms are worth making They included poor type-faces, wrong size of type in relation to the length of line, too yellow a paper, paper too bulky, paper of different colours in the same issue, too many type faces (and therefore added costs), generally poor quality of diagrams, and, with one exception, unnecessarily drab colours of the covers He wondered why journals did not print more frequently on both sides of the art paper used for plates He suggested that some schools of art or of printing would welcome the opportunity to re-design a journal The defence to Mr Wilson's arguments was that more attractive layouts usually cost more money, and if costs increased by, say, 10 per cent, then 10 per cent fewer papers would be published, to which Mr Wilson rejoined that there is little use in printing papers if they are not readable The general feeling among the editors was that presentation could certainly be improved and that this could be done in collaboration with the printer. A useful suggestion made during this discussion was that the page numbers should be printed on the spine of each part

Mr Hislop (Hislop and Day) discussed methods of blockmaking He thought that geological diagrams were better than the average, his main criticism being that originals are generally too large Reduction to less than half size should be avoided He reminded editors and authors of the necessity of marking the top of each photograph, and of having soft rather than contrast prints Contrast can always be increased but not reduced He thought that Letraset was good for lettering and recommended a new photographic process of lettering called Starlettograph-Lichtsatz (Munich)

Mr Douglas Grant (Oliver and Boyd) reminded editors of the necessity of watching costs They should ask for detailed invoices from their printers so that the costs of the different items such as paper, composition, corrections, machining, etc, can be determined Offprints should be ordered before printing so that the required number of plates, and in long articles certain of the printed sheets, can be run off during the main printing Variations in type sizes and type faces can increase printing costs and should be reduced to a minimum a supply of reviews and short articles should be kept so that the part can be brought up to a multiple of 16 pages wherever possible vertical rules in tables should be removed because of the expense of setting

The meeting was told by Mr Inglis (Oliver and Boyd) of discounts, commission and distribution. Individual small costs add up to impressive totals, ranging from invoices at ½*d* each, through envelopes costing 1½*d* to 6*d* for the carton sizes, to postages for larger parts at 2*s* 3*d* Small wonder that some journals (not geological as yet) find it difficult to run to six parts annually and are considering a quarterly issue

Index cards, the last item on the agenda, had been tried out by the editors of the *Transactions of the Edinburgh Geological Society* in a recent issue, with the view of providing subscribers with abstracts for use in filing systems Each copy contained 5 in × 3 in cards, one for each of the papers, bearing the author's name, title of the paper, journal reference and the author's abstract (not exceeding 250 words) The cost worked out at a little less than 1*d* a card and represented some 3 per cent of the total cost of the part Such cards were welcomed, but it was felt that their spread to other journals would be more influenced by subscriber pressure than by editorial decision

The overall impression at the end of the two days of useful discussion was that it was greatly to the advantage of journals that the editors should see more of the printer and that a more satisfactory relationship should be established between author, editor and printer

COAL PETROGRAPHY

THE International Committee for Coal Petrology has recently prepared a second edition of its *Handbook of Coal Petrography* which has now been published by the Centre National de le Recherche Scientifique, 15 Quai Anatole-France, Paris 7^e English, German or French texts are available from this organization and the Russian text from the Academy of Sciences of the U S S R, each volume costs 54 N F Since normal retail channels will not be used for distribution of this work, a member from each nation represented on the Nomenclature Sub-committee of the International Committee has been asked to contribute a short note about the *Handbook* to an appropriate journal in his or her country In this way it is hoped that coal scientists and petrographers working in related fields will be made aware of the existence of the *Handbook* and can obtain a copy, if they wish, from one of the aforementioned sources

The first edition of the *Handbook* was published in 1957 in glossary form The second edition has been considerably expanded and revised It is divided into two parts, the first and lengthier dealing with nomenclature, the second describing methods of petrographic analysis

The original publication of 1957 was concerned mainly with the Stopes–Heerlen system of petrographic nomenclature of coals and their constituents that is used primarily in Europe Further terms have been added to this system in the intervening six years, and the new definitions are now included in the *Handbook* together with a considerable number of terms from the Thiessen-Bureau of Mines system of nomenclature This is the other principal system of petrographic classification and it is used mainly in the United States A brief outline is also given of the important nomenclature recently introduced in the United States by Prof Spackman A summary of the genetic classification of the Geological Institute of the Academy of Sciences of the U S S R is also included as well as definitions of eleven of the more important terms from this system Definitions of a number of general terms used in coal petrology have also been added to the *Handbook*

Only the petrographic nomenclature of the 'hard coals' (bituminous coals and anthracites) is considered in the *Handbook* The petrography of the soft brown coals is still under discussion by the Nomenclature Sub-committee and no terms or definitions have yet been published The *Handbook* is in the form of a strong loose-leaf folder made up of sheets approximately 9½ × 6¼ in. in size In the nomenclature section, 47 of the 149 sheets are plates composed of 108 photomicrographs, 4 sheets contain line diagrams Eighty-one terms have been defined in this section, the text giving details of origin, description and, in the case of macerals, microlithotypes and lithotypes, their occurrence and practical importance Where possible, correlation of terms with those in other systems of nomenclature have been made Photomicrographs that illustrate various features have been taken where necessary by transmitted and reflected light, many are in colour

Methods of analysis have been included in the *Handbook* because they have helped substantially towards better definitions of the petrographic constituents of coals The Analysis Sub-committee was formed in 1955, and the second short section of the *Handbook* presents the findings of the Sub-committee since then Exchange of approximately 100 samples between petrographic laboratories in different countries has led to considerable improvement in maceral and microlithotype analyses, as well as to the formulation of recommendations for the preparation of samples and their examination in reflected light Sixteen sheets, two being plates and one a line diagram, are devoted to general notes on methods of quantitative analysis of polished coal surfaces, maceral and microlithotype analyses on particulate blocks and suggested procedures for the preparation of samples

Although the nomenclature of the 'hard coals' is now well established, the definitions presented in the *Handbook* are not necessarily final Amendments may be made in the future and further terms added to the different systems of nomenclature All terms and definitions do, however, accord so far as possible with the present state of knowledge in coal petrology D G MURCHISON

EXPLORATION OF THE SEA

THE total water-surface of the Earth is estimated at 70 8 per cent of its area, and of this the overwhelming proportion is represented by the oceans Geological science has done much to elucidate the nature, composition and structure of the Earth's surface, aerial reconnaissance and especially modern geophysical techniques have, during the past four decades or so, materially increased our knowledge, but it still remains relatively superficial The nature of the Earth's interior, be it liquid core or otherwise, is largely a matter of hypothesis, although the Operation Mohole project launched in 1961, to drill a hole 7 miles deep into the mantle-rock from a ship stationed north of Puerto Rico, may, if successful with samples from depth, throw further light on the problem By contrast, exploration of space, the atmosphere and beyond, is being pursued on a vast and ever-increasingly costly scale by means of instruments borne by rockets and Earth satellites; in the near future we may find out what is the geology of the Moon

In a recent lecture, Sir Frederick Brundett, referring to the comparative neglect by science of the sea, is reported to have said that "The world must be *mad* to spend more in a year on space research than has been spent on studying the oceans in the last hundred years" In a paper read before the Royal Society of Arts (*Journal*, 111, No 5086; September 1963) Dr T F Gaskell, scientific adviser in the Information Department, British Petroleum Co, Ltd, formerly with the Royal Naval Scientific Service engaged in research in anti-submarine mine counter-measures and beach reconnaissance, pursues this theme, explaining why advances in our knowledge of the sea have been slow, what is the trend of contemporary oceanic investigations and what lies in store economically and scientifically as we learn more of the sea in future

Dr Gaskell makes some pertinent points at the outset The sea is a difficult place in which to work "Sea-water is opaque and this is the first difficulty that faces the oceanographer Most of the tools needed to investigate the sea must use physical principles which are more complicated than the optical methods that are so satisfactory for studying the surface features of the land"

" sea-water contains enough salt to be neither a really good conductor of electricity nor a useful insulator, so that in this respect also it is more difficult to work in than is the atmosphere The salt water also militates against the scientist by being corrosive, and to ensure that experiments shall be conducted with the maximum of difficulty and discomfort, the sea surface is seldom still " Again, "The greater part of the oceans is about three miles deep, so that when apparatus must be lowered to the sea-bed long cables are needed"

Undoubtedly the navies of the world, especially those of the great maritime powers, during and since the Second World War, have contributed much to our knowledge of the sea itself, also of the shape of the deep sea-floor; this is an important factor for submarines, now accustomed to diving much deeper and staying submerged far longer than formerly Detection of submarines demands an understanding of sound-wave propagation in the sea-water medium, which in turn requires more accurate measurements of temperature and density distribution in the oceans Of the more peaceful aspects of future ocean investigations are off-shore drilling for new oilfields or important extensions of known continental developments, these projects are proceeding apace to-day and, apart from oil-finding, every hole drilled provides more information of sedimentary accumulations, past and present, forming the continental shelves concerned In the long run, however, it is the fish in the sea that will take pride of place in future oceanic researches Increase in world population will compel more attention to the sea as a vast food-producer As Dr Gaskell observes. " we hunt the fish that Nature provides, just as our ancestors hunted animals for food We have not yet begun to herd fish or to improve their quality—but one day we shall be forced to farm the seas as we do the land"

H B MILNER

THE ROWETT RESEARCH INSTITUTE

THE report of the Rowett Research Institute for the year 1962–63 * is on the same lines as that for the previous year; that is to say, the main section of the report summarizes the numerous papers which have appeared during the year and supplements these summaries with additional unpublished information so as to bring the accounts of the research more nearly up to date In all, some 150 original papers published by workers in the Institute are referred to, together with references to about 40 papers in preparation and other unpublished observations These considerable numbers give some idea of the great mass of work proceeding in the Institute, and of the magnitude of the task of presenting a succinct and intelligible account of it within reasonable compass In addition to this general account of present research within the Institute, the report contains two special contributions on topics deemed to have reached a stage suitable for review

Both these review articles deal with topics of considerable practical importance in British agriculture The first, by Dr T R Preston, discusses recent work on high-energy barley diets for livestock feeding It has been found that, with suitable management, beef cattle may be reared on a diet of 85 per cent of appropriately treated barley and a 15 per cent supplement containing protein, minerals and vitamins Animals so fed gain weight in the form of lean beef surprisingly rapidly, and it was found possible to bring some dairy-type cattle to a good finish in 10–12 months instead of the usual 18–24 months The régime, therefore, promises to be economic and profitable and has excited considerable interest among the farming community It has been introduced into commercial practice, but the resulting meat has encountered some criticism on the ground of taste and texture Dr. Preston's article surveys the scientific background of this topical and somewhat controversial subject

The other review, by Dr E Cresswell, deals with two topics both in connexion with sheep The first is the problem of the premature dropping of the incisor teeth by certain sheep, more especially mountain breeds on particular diets The causes of this curious defect have been rather obscure, and an account is given of investigations into the course of abnormal development of the teeth and the means which have been suggested to prevent or minimize the trouble The second part of this article deals with the problem of providing suitable shelter for sheep during winter storms on mountains or other exposed places Plans are given of a type of 'stell', which is relatively cheap to construct and which provides shelter for about 100 sheep and at the same time ensures adequate ventilation Animals so protected are able to pass the winter on the more exposed mountain pastures and do not need to be brought to lower ground for protection from storm and cold

In a section of the present report giving a brief survey of the past year, reference is made to the fact that in 1963 the Rowett Research Institute celebrates its Golden Jubilee (see *Nature*, 200, 201, 635, 1963) It was in 1913 that a joint committee of the University of Aberdeen and the North of Scotland College of Agriculture initiated its research programme on the nutrition of farm animals and appointed Dr John Boyd Orr (now Lord Boyd Orr) to carry out this novel enterprise The work on animal nutrition has gone on without interruption ever since, apart from dislocations due to two world wars The contents of this report demonstrate how vigorously the organization then born has grown, and how it has justified and rewarded the efforts of the pioneers who created it fifty years ago

THE MEDICAL RESEARCH COUNCIL

THE report of the Medical Research Council for the year 1961–62*, which follows the general plan of this Council's previous reports, reflects, as they did, the trend of medical research as a whole The volume and wide range of the work being done by the Council's staff and the practical applications of their work are indicated by the fact that their publications have now become so numerous that it is no longer possible to list them in the report, although details of them can be obtained from the Library of the National Institute for Medical Research, Mill Hill, London, N W 7

Apart from the usual summaries of researches in progress, which occupies 140 pages of this report, and the details of the personnel employed by the Council, the report includes, as previous reports have also done, a section entitled "Some Aspects of Medical Research", which is also published separately under the title *Current Medical Research* (H M S O 5s. 6d) This particular section is this year made up of eleven articles, the range and content of which can be only briefly indicated here

---

* Committee of Privy Council for Medical Research Report of the Medical Research Council for the Year 1961–1962 Pp viii+284 (Cmnd 2075) (London H M S O , 1963) 16s 6d net

The first article, entitled "The Genetic Code", includes in its scope the work on this subject for which four members of the Council's staff, Dr M F Perutz, Dr J C. Kendrew, Dr F H C Crick and Prof M H F Wilkins, were, together with Prof J D Watson, awarded Nobel Prizes for 1962 (see *Nature*, 196, 319, 519, 1962) The second article, entitled "Chemical Mutagens", discusses chemical substances which may produce mutations and their mode of action and their specificity The third article is on cell transformation by tumour viruses, with special reference to the polyoma virus which is being studied under the direction of Prof M G P Stoker in the Council's Experimental Virus Research Laboratory at the University of Glasgow Next comes an article on "Cancer in the Tropics", and this is followed by a discussion of "River Blindness" caused by the parasitic nematode worm, *Onchocerca volvulus*, in tropical Africa, an article on the demyelinating diseases, and another on the central nervous control of the endocrine glands and the influences exerted by hormones on the central nervous system Then follows a valuable article on the relationship between mental retardation and chemical abnormalities in the body Two articles discuss the metabolism of plasma protein and the biosynthesis of sterols, and finally there is an article on biological engineering, a term of which the author of the article apparently does not fully approve It refers to the various ways in which engineering techniques are nowadays applied to medicine and the biological sciences, and includes such devices as radio-pills and other 'miniaturized' instruments, the whole-body plethysmograph, the conicycle, which measures the content of respirable dust and other aerosols in the air, the breath-alcohol detector, and the remarkable prostheses which are now available as artificial limbs and other artificial aids, such as plastic heart valves, artificial kidneys, heart–lung machines, and aids for the blind and deaf The value of this whole section is increased by photographs of a molecular model of deoxyribonucleic acid, of polyoma virus particles and cells transformed by this virus, of a radio-pill and a prosthesis for the arm.

The rest of the report, apart from the details it gives of the finance and administration of the Council's work, pays a well-deserved tribute to the work of Sir Charles Harington, who retired on July 31, 1962, from his post as director of the National Institute for Medical Research, after serving in that capacity for twenty years (see *Nature*, 195, 228, 1962) During this period the Institute's scientific work was greatly extended, the number of its staff increased from 35 to 125 and the Council enjoyed the great benefit of Sir Charles's advice on both research and policy Everyone interested in the Council's work will be glad to know that Sir Charles will still be available as consultant adviser to the Council's secretary

In another section on the Council's Advisory Boards it is explained that knowledge and research have become so complex that the Council, which has always been averse to "any arrangement which implies that one single body should bestride the field of clinical or any other type of research", has devised a system of Boards which are, in effect, sub-councils The first of these, the Clinical Research Board, was appointed in 1953 Afterwards, a Tropical Medicine Research Board was established, and in 1962 a Biological Research Awards Committee was created By means of these Advisory Boards, which enable the Council to benefit from the advice of many experienced specialists, the Council is able to decentralize effectively the ever-increasing complexity of its work

No one can doubt, after reading these well-written and closely reasoned pages, that here we have an organization of scientists working together and directing their own work free from Governmental control, which ensures, as no other kind of organization can do, that all the sciences, whether they are primarily medical or not, are effectively integrated together for the benefit of man and other animals Long may it continue to produce the remarkable results that, year by year, are recorded in its reports G LAPAGE

THE LIQUID STATE

THE Institute of Physics and the Physical Society held a conference on "The Liquid State" at the Imperial College of Science and Technology, London, during September 9–13

The study of the structure and properties of liquids, like many branches of classical physics, is a subject in which real progress is now slow and irregular There was a burst of activity after the Second World War in which the implications of the integral equations for the distribution functions of Yvon, Kirkwood, Born and Green were studied and in which the limitations of Kirkwood's 'superposition' approximation came to be appreciated This was followed by an advance in 'experiment' when, in the 1950's, computers were used to calculate the pressure and rate of approach to equilibrium of systems of simple molecules by, for example, the solution of the equations of motion of a small representative assembly This work gave an impetus to the study of simple models, and the past two years have seen the development of at least two new sets of integral equations and for one of them, the equations of Percus and Yevick, their exact solution in closed form for a system of hard spheres Meanwhile, there have been substantial advances in the theory of transport properties, although there is still argument about the legitimacy of some of the steps that are necessary to relate these properties to the intermolecular forces These developments were reflected in many of the 68 papers presented at this conference, and a selection of these are described briefly in this report

The first day was a discussion of methods of determining structure In the opening review, Dr P A Egelstaff (Atomic Energy Research Establishment, Harwell) emphasized the power of the method of neutron-scattering Thermal neutrons can show shifts of both wave-vector and energy when scattered by liquids and so can be used to supplement the information from X-ray diffraction and light-scattering experiments Dr S J Cocking (Atomic Energy Research Establishment, Harwell) illustrated this in outlining his investigations of the motion of atoms in molten lead Dr J A Elliot, Prof H E Hall and Dr J M Williams (University of Manchester) described the use of the Mossbauer effect for the study of diffusion in glycerol, and Dr J G Powles (Queen Mary College, London) has used nuclear magnetic resonance to examine rotational relaxation

Prof J D Bernal and Miss S V King (Birkbeck College, London) reported further experimental studies of random close-packed arrays of steel balls, and suggested that such arrays often showed long ordered lines of particles This point was taken up the next day when Dr B J Alder (Livermore, California) discussed his computer calculations on the transition from ordered to fluid phase in a two-dimensional array of hard disks. He suggested that melting might start when lines of molecules could slide past each other Hitherto Bernal's studies have had little contact with more conventional theories of liquids, but an attempt to bridge this gap was made by Prof R Furth (Birkbeck College, London)

PHYSICS DEPARTMENTAL LIBRARY

At the end of the first day, Prof D H Everett (University of Bristol) showed a film of the motion-in-a-plane of an array of cork balls agitated by a stream of air Again, co-operative motion in lines and rings could be seen

The longest session of the conference was on the equilibrium properties of pure and mixed liquids and occupied the second and third days It was introduced by Prof J de Boer (University of Amsterdam), who set out the present position both of lattice theories and of calculations of the pair distribution function In the latter he outlined the 'hyper-netted chain' approximation on which he and other groups have been working recently In the papers that followed, only Dr J A Barker (Commonwealth Scientific and Industrial Research Organization, Melbourne) used the lattice model for liquids, in a version which he calls the 'tunnel' model He uses the fact that combinatorial problems in one dimension present little difficulty to choose a model in which the molecules have complete freedom of motion in one direction only His comparisons of theory and experiment were outstandingly successful

The mathematical properties of the distribution function and some inequalities that they must satisfy were set out by Dr J L Lebowitz (Yeshiva University, New York), Dr J. K Percus (University of New York) and Dr O Penrose (Imperial College of Science and Technology) The first author also presented his solution of the Percus–Yevick equations for mixtures of hard spheres Prof J S Rowlinson (Imperial College of Science and Technology) has obtained numerical results for this model and showed that the excess Gibbs energy is always negative and hence that phase separation cannot occur This conclusion was consistent with the calculations of Mr M Rigby and Dr E B Smith (University of Oxford) on the fourth virial coefficients of mixtures of hard spheres The extensive cancellation of cluster integrals that characterizes both the hyper-netted chain and the Percus–Yevick approximations was, to a degree, justified by the calculations of Dr H N V Temperley (Atomic Weapons Research Establishment, Aldermaston) for molecules with Gaussian repulsions Dr J Walkley (Imperial College of Science and Technology) discussed the quantal treatment of a cell model of an assembly of hard spheres

Papers on the two-dimensional lattice gas were presented by Dr D M Burley (University of Sheffield) and Dr M E Fisher, Dr D S Gaunt and Dr J Stephenson (King's College, London) In some cases such a fluid appears to show a second-order transition to an ordered state

Three of the experimental papers of this section aroused much interest Mr A T J Hayward (National Engineering Laboratory, Glasgow) has started measurements of the equation of state of liquids under tension and is repeating the more common measurements of the maximum tensions that liquid can bear Dr G Casanova and Dr A Levi (University of Genoa) showed that their measurements of the isotopic separation factor at a liquid-vapour equilibrium can be used to measure $\nabla^2 U$, where U is the configuration energy of the liquid, and it was suggested in discussion that their measurements provided also a means of testing intermolecular potentials without any assumptions about the structure of the liquid Dr J J M Beenakker, Dr M Knoester and Dr K W Taconis (University of Leyden) have developed a flow calorimeter for the direct measurement of the heat of mixing of compressed gases, a quantity that has hitherto been obtained only indirectly

The properties of mixtures of linear hydrocarbons are of interest because they are regular functions of the chain-lengths Prof D H Everett (University of Bristol) and Dr Th Holleman and Dr J Hijmans (Royal Dutch Shell, Amsterdam) extended correlations of theory and experiment to high temperatures where the heats of mixing are negative Dr I A McClure and Dr F L Swinton (Royal College of Science, Glasgow) reported volumes of mixing from some well-chosen systems in which the size ratios of the molecular pairs were close to 2 1

Transport properties were discussed on the fourth day The introductory paper was by Prof I Prigogine and Dr P Résibois (University of Brussels), who summarized the statistical mechanics of irreversible processes and, in particular, its application to ionized systems They emphasized the difficulty of treating thermal diffusion in such systems This paper was followed by a substantial contribution from Prof R Eisenschitz and his colleagues (Queen Mary College, London) in which they tested both the theories of Kirkwood (that is, the introduction of a 'friction constant') and of M S Green The former was confirmed by calculations on a simple harmonic model of a crystal with a temperature gradient Rice and Allnatt have suggested that the fundamental dynamical event in a liquid can be represented as a 'hard-core' repulsion of a pair of molecules, followed by their Brownian motion in the field of their neighbours Dr S A Rice and Dr E G Wilson (University of Chicago) tested this assumption by comparing its predictions with four of the transport coefficients of the rare gases Dr E McLaughlin (Imperial College of Science and Technology) emphasized the importance of the coefficient of thermal expansion of a liquid in determining the temperature coefficient of the thermal conductivity He illustrated this by calculations on simple models

Two experimental papers were on the subject of nucleation Dr L O Roellig (Wayne University, Detroit) showed that the probability of a particle of ionizing radiation destroying a super-heated state can be related to the amount of energy it can transfer to a small volume of liquid Dr E R Buckle (Imperial College of Science and Technology) showed, by means of a cloud-chamber, that the freezing of super-cooled ionic melts is critically dependent on temperature, a dependence which he ascribed to the threshold effect of spontaneous nucleation The final paper of this session was by Dr T A Litovitz (Catholic University, Washington), who compared the dielectric (or rotational) time of relaxation with the ultrasonic (or structural) time He showed that the former was the longer and that both changed from a single time to a distribution of times in liquids in which the viscosity did not show a simple exponential dependence on temperature

A widespread dissatisfaction with the present theoretical basis of many of the approximations that are used in discussing the transport properties of liquids led to an unscheduled discussion of fundamentals on Friday afternoon The principal speakers were Dr Résibois, Prof Eisenschitz and Dr Lebowitz

Liquid metals were discussed on the last day, and, of necessity, most of the papers in this part of the conference were concerned with specifically electronic (and hence quantal) effects Dr S F. Edwards (University of Manchester) reviewed the present state of the theory of electrons in liquid metals He applied methods adapted from field theory to the calculations of momentum and energy distributions in disordered potentials, and demonstrated that, while at present there can be no detailed comparison of theory with experiment, this goal is coming within reach Experimental work on soft X-ray spectroscopy, transport and optical properties, positron annihilation, and electron spin resonance all have a part to play An alternative route to some of Edwards's conclusions was provided by Dr D Libermann (University of California)

Two of the papers of this section sought to extend to liquid metals concepts which have been useful in non-electrolytes Dr W B Mott (Atomic Energy Research Establishment, Harwell) examined Hildebrand's rule for the calculation of mutual solubility of two liquids He was able to modify it to produce qualitative agreement for most metallic systems More ambitiously, Dr E Morris (Atomic Weapons Research Establishment, Aldermaston) attempted the calculation of the critical properties of metals from the principle of corresponding states The agreement with experiment for mercury was only fair

Three experimental papers from the University of Birmingham by Dr J R Wilson, Dr G H Laurie and Dr J N Pratt revealed the anomalous dependence on temperature of the resistivity and partial molar properties of the systems Hg + Tl, Mg + Pb, and Sn + Pd + Ag These were ascribed to variations of the degree of local order with temperature, and to the formation of intermetallic compounds Dr R V Hodgson (University of Birmingham) measured the resistivity of five binary semiconductors and showed the change towards metallic properties at high temperatures Finally, Dr D T. J. Hurle, Dr J B Mullin and Dr E R Pike (Radar Research Establishment, Malvern) described the growth of single crystals of semiconductors by a zone-melting process in which a d c electric current passed along the bar

The chairman of the Organizing Committee of the conference was Dr. H. N V Temperley The proceedings are not to be published as a separate volume

OBSERVED TRIPLICATION OF *PKP*

By Dr R D ADAMS and M J RANDALL

Seismological Observatory, Department of Scientific and Industrial Research, Wellington, New Zealand

DETAILS of the variation of seismic velocity near the boundary of the inner core have always been uncertain, and so, correspondingly, has the theoretical travel-time curve of *PKP* in the distance range immediately beyond 143° On the model of Jeffreys and Bullen[1] a short branch extends beneath the PKP_2 curve from the cusp at 143° to 147° The tables of Gutenberg and Richter[2] incorporate a similar branch extending to 169°, with arrival times between those of PKP_1 and PKP_2 for distances greater than 150° No observations have been reported in confirmation of either of these branches

Bolt[3] has recently reconsidered the velocity variation near the boundary of the inner core, with a view to accounting for Gutenberg's observations of early arrivals of *PKP* at epicentral distances in the range $125° < \Delta < 140°$ (ref 4) His preferred solution shows a branch of the *PKP* travel-time curve, labelled *GH* which not only includes these early arrivals but also continues to a cusp *H* at $\Delta =$ 156 5°, for distances greater than about 146° the travel times are between PKP_1 and PKP_2 We have recently found arrivals which confirm the latter part of the *GH* branch These arrivals, which for convenience we have called PKP_3, have been taken from the seismological bulletins of stations which lie in the distance range $148° < \Delta < 156°$ from certain New Zealand earthquakes New Zealand stations have also recorded the triplication of *PKP* from earthquakes at appropriate distances On these records PKP_3 is a stronger arrival than PKP_1, being comparable with PKP_2 Three branches of *PKP* have also been reported by Hai[5] from deep-focus earthquakes near Fiji

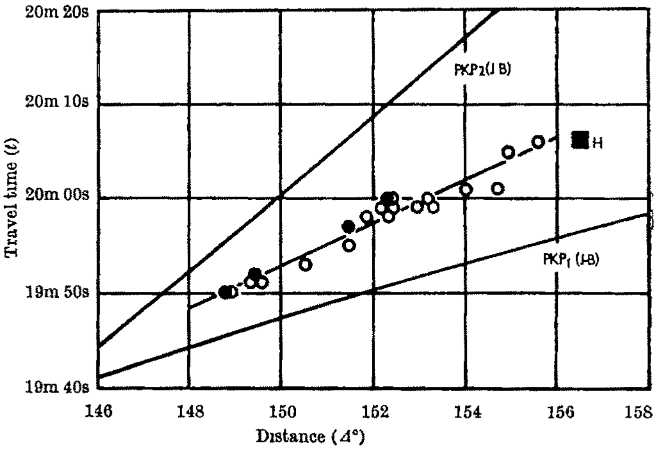

Fig 1 Observed travel times of PKP_3 Solid circles represent two arrivals The position of Bolt's cusp *H* is shown

Additions to the New Zealand network of seismograph stations have enabled the foci and origin times of recent New Zealand earthquakes to be determined with improved accuracy PKP_3 arrivals have been identified from five New Zealand earthquakes for which we have obtained foci and origin times by least squares from numerous observations. Table 1 lists these earthquakes and gives the standard errors of the solutions Table 2 gives the epicentral distances to the stations at which PKP_3 has been found, the increased number of stations now operating in Scandinavia provides more observations of *PKP* in the relevant distance range Arrivals reported from stations at distances less than 148° have been discarded because one cannot be certain which *PKP* branch they belong to

Fig 1 shows the travel times of the PKP_3 arrivals, adjusted so as to correspond to a surface focus. The Jeffreys–Bullen travel-time curves for PKP_1 and PKP_2 are also shown, many arrivals corresponding to these branches were also reported for the same earthquakes All but three of the PKP_3 arrivals have been reported as impulsive, and the standard errors of the epicentral distances and origin times are such that there seems no possibility of these arrivals being either PKP_1 or PKP_2 At some stations there are arrivals corresponding to each of the three branches, for example, Skalstugan reports three impulsive arrivals from earthquake 3, with travel times of 19 min 53 sec, 19 min 59 sec and 20 min 13 sec Uppsala also reports triplication of *PKP* for the same earthquake The largest distance at which we have identified PKP_3 is 155 6°, the branch does not appear to extend as far as 157 5°, where some stations have reported PKP_1 and PKP_2, but not PKP_3 The position of Bolt's

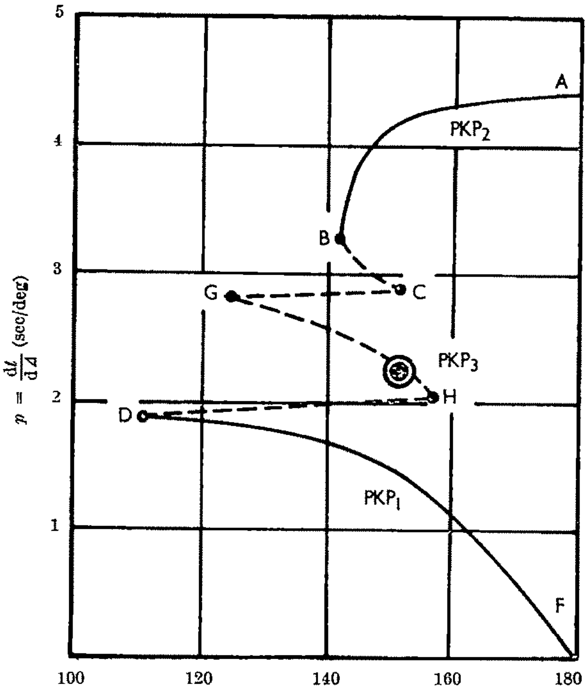

Fig 2 p, Δ diagram corresponding to Bolt's model, showing the observed value of p for PKP_3

predicted cusp H is shown, lying close to the end of the line of PKP_3 observations These observations would thus appear almost certainly to correspond to the upper part of the GH branch of Bolt's travel-time curve Hai's observations[5], when adjusted for depth, appear to be close to ours, though he also suggests a possible extension of the observations to 160°

The 25 observations of PKP_3 shown in Fig 1 were fitted to a straight line as follows

$$t\ (\text{sec}) = 1196{\cdot}9 \pm 0{\cdot}2 + (2{\cdot}24 \pm 0{\cdot}12)(\Delta - 151{\cdot}8°)$$

Adding a quadratic term does not significantly improve the fit Near 151·8°,

$$p = \frac{dt}{d\Delta} = 2{\cdot}24 \pm 0{\cdot}12 \text{ sec/deg}$$

The p, Δ diagram is given in Fig 2 The detail of the curve between adjacent cusps is not readily obtainable from the t, Δ diagram in Bolt's paper, the branches corresponding to PKP_1 and PKP_2 have been derived directly from the Jeffreys–Bullen tables The value of p found from the observations of PKP_3 near 151·8° is shown, and agrees well with that predicted by Bolt Since the slope of the p, Δ curve at a given distance is proportional to the amplitude of the seismic waves, the rather large amplitudes which have been observed for PKP_3 suggest that the slope of the p, Δ curve for the branch GH is greater at the larger distances, as is shown in Fig 2

Thus the observations presented here are in good agreement with Bolt's prediction with respect to travel time, range of epicentral distance, and slope of the travel-time curve We hope to carry out a more detailed investigation of PKP arrivals at relevant distances as further observations become available

We acknowledge the help we received from station bulletins, and we also thank Dr Markus Båth for supplying readings from the Swedish network

WAVE-LENGTH STABILIZATION OF AN OPTICAL MASER

By Dr W R C ROWLEY and D C. WILSON

National Physical Laboratory, Teddington, Middlesex

THE properties of the gaseous type of optical maser make it a light source of great promise for use in interferometric measurements of length. The coherence in time and the extremely narrow band-width of the radiation enable interference effects to be observed over paths many times greater than possible with conventional sources[1] Moreover, the coherence across the diameter of the light beam leads to simplifications in the construction of interferometers

The use of the 6328 Å line of the helium–neon maser for interferometric length measurements is hindered because, in spite of its narrow band-width at any instant, the wave-length of the light can vary The emitted wave-length is broadly determined by the energy difference of the levels involved in the transition and by the Doppler effect due to movements of the atoms in precisely the same way as is the wave-length of a normal spectral line spontaneously emitted from a discharge tube The precise wave-length of the maser emission, within the wave-length range corresponding to the width of this Doppler broadened profile, is determined by the effective length of the optical cavity This means that the wave-length may lie anywhere within a range of about 2 parts in 10^6 according to the precise length of the cavity, and there is the possibility of several slightly different wave-lengths being emitted simultaneously through multi-mode operation

A simple way of improving the wave-length or frequency stability of the maser is to use the Doppler broadened profile of the transition as a reference and to adjust the length of the cavity so that the maser emission corresponds to the peak of the profile[2] In the technique to be described the length of the cavity of the maser is adjusted continuously by a servo control system through a simple electromechanical coupling With this device the frequency drifts are reduced to only 1 or 2 parts in 10^8

Principle of operation An idealized diagram of the gain coefficient of the maser as a function of the frequency of its emission is shown in Fig 1 This curve is the spontaneous emission spectral profile and its shape is principally due to Doppler effect In practice the curve of maser gain against emission frequency is narrower than the curve of Fig 1 because of the threshold for maser action due to optical losses in the cavity For low input powers to the discharge, only the axial mode[3] nearest the peak of the profile has a gain greater than the threshold level In this condition the maser output intensity is strongly dependent on the operating frequency, with a peak at the frequency of maximum gain

If one of the mirrors of the optical cavity is caused to vibrate very slightly, then the maser frequency oscillates and the maser output is amplitude modulated as indicated in Fig 1 The phase of this modulation relative to the imposed vibration will depend on whether the mean frequency of operation is greater or less than the frequency at which the gain is a maximum When the mean maser frequency is at the peak of the gain curve, the fundamental intensity modulation vanishes, leaving only a slight harmonic component. The intensity modulation can thus be used as the basis of a servo control system to keep the maser frequency centred on the peak of the gain curve.

Mechanical arrangement. The maser to which the control system has been applied is one of the helium–neon type operating on the red line at 6328 Å. It utilizes a radio frequency excited discharge tube fitted with Brewster angle windows which is set between the mirrors of the optical cavity. These mirrors are both concave, having 1 m radius of curvature, and are separated by 750 mm. The framework of the cavity is a structure of four 1.5-in diameter invar rods with several cross-members in addition to the end-pieces. The mirrors are mounted in detachable end-plates which are held by springs in position against their adjusting screws.

The control movements for vibrating one of the mirrors and for adjusting the length of the cavity are both achieved with a single relay coil mounted on the end-piece of the main frame, its armature bearing against the end-plate carrying the mirror (Fig. 2). A current of 50 m.amp through a 200-ohm coil gives almost 2 lbf of thrust, which is sufficient to move the mirror through a distance of several half-wave-lengths by elastic deformation of the end-plate and its supports. This arrangement gives a rotational movement to the mirror rather than a pure translation, but this does not seriously affect the operation of the maser, for the diameter of the maser beam is only about 1 mm, whereas the distance from the mirror centre to the axis of rotation is about 60 mm and so a mirror movement of a few half-wave-lengths corresponds to a misalignment of only a small fraction of a wave-length across the beam diameter.

A direct current is passed through the relay coil, thus biasing it so that there is always a force holding the armature in contact with the end-plate, and to this current is added the control current which keeps the maser length correct. At the same time a small alternating current at 350 c/s, passed through the coil, causes the mirror to vibrate with an amplitude of a small fraction of a wave-length. The intensity variation of the maser beam resulting from this vibration is detected with a photo-diode and, after amplification, is passed into a phase-sensitive rectifier. The rectified output, after smoothing, is a direct current proportional to the input, and is either positive or negative according to the phase of the input relative to that of the alternating current fed to the relay coil. This direct current is the control current which is added to the steady bias current through the coil. The control system is thus a feedback arrangement. Should the maser frequency not be centred exactly on the profile, then there is an intensity modulation which is detected, amplified and fed back to reduce the amount of the departure. The gain of the feedback loop determines by what factor the maser frequency drifts are reduced.

Performance. The stability of the controlled wave-length of the maser has been measured by comparing it with the orange line of krypton-86, which is the primary wave-length standard. The comparisons have been made using a Fabry–Perot interferometer with photoelectric detection in which spectral lines from two sources are effectively compared simultaneously and their interferograms are recorded automatically on punched paper tape. A digital computer analyses the results and can detect relative changes in wave-length down to 2 parts in 10^9. The absolute accuracy within which one source can be compared with another is, however, limited by geometrical differences in the optical paths to only one or two parts in 10^8.

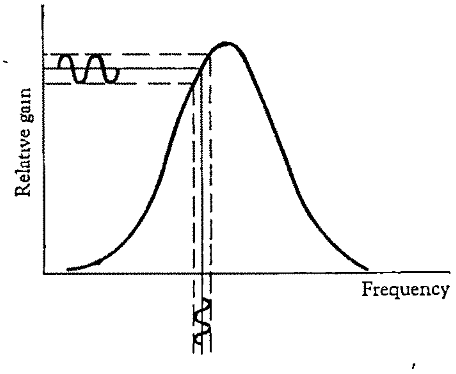

Fig. 1. An idealized diagram of the gain of a maser as a function of frequency, showing how a frequency modulation results in a modulation of the gain and hence of the output intensity

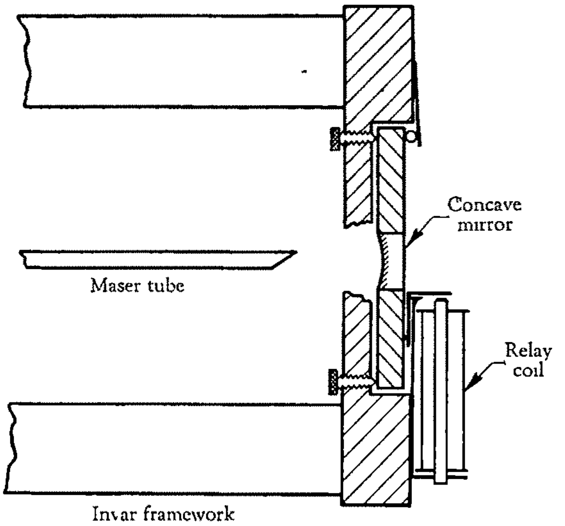

Fig. 2. Diagrammatic view of one end of the maser frame. The armature of the relay coil bears against the mirror mount which moves by elastic deformation, even though the mounting has not deliberately been made flexible

With a loop gain of the stabilizing system of about 100, the measured drifts of maser wave-length are less than 1 part in 10^8, provided that manual readjustment of the cavity length is made from time to time if thermal expansion causes the framework to change length by much more than a wave-length. Any change in the length of the framework is apparent as it causes a corresponding change of control current through the relay coil.

The maser frequency, being controlled to the peak of its intensity profile, is altered by any effect which influences the shape or shifts the frequency of this peak. Any change in the pressure of helium and neon in the discharge will shift the peak frequency, but as the pressures involved are low the effect amounts to a few parts in 10^8 at the most. This has been confirmed by measuring the wave-length emitted by the maser when fitted with different discharge tubes. With an old discharge tube in which the gas pressure was much reduced through use, the emitted wave-length was identical, within the accuracy of the experiment (2 parts in 10^8), to that emitted when the discharge tube was replaced by a new one.

The effective intensity profile for maser action is influenced by maser action itself. The effect known as 'hole burning'[4] distorts the profile particularly in the region of the peak. This effect can lead to an actual dip at the centre of the profile[5,6], but it is not readily observable. There is some asymmetry of the spectral profile owing to the isotopic content of natural neon, and hole burning thus gives rise to an asymmetrical effect which shifts the profile peak towards higher frequencies. The shift appears to be proportional to maser intensity, and a total frequency change of 2 parts in 10^7 is observed over the intensity range from threshold to the maximum intensity at which single mode operation can be maintained with the maser being utilized.

As this latter intensity is ten times greater than that normally utilized when using the maser for interferometry in this Laboratory, the uncertainty of frequency arising from the effect need not be more than 1 part in 10^8. It does, however, mean that some control over the mean maser intensity is advantageous. A portion of the maser beam is reflected from a glass plate on to a cadmium sulphide photo-conductive cell for this purpose. The output from this cell is used to control the power supply of the discharge tube oscillator and thus stabilizes the maser intensity. The maser at present controlled as described here has a vacuum wave-length of 6329·9141 Å at threshold level for maser action.

Because the vibrating mirror imparts a frequency modulation to the maser output, the band-width of the emission is effectively broadened. The amount of the modulation is, however, small and does not upset interferometric work over paths of several metres. For radio frequency beat experiments or for interferometry over longer paths the modulation would be troublesome, but it could be overcome by a more elaborate servo system in which the mirror vibration could be stopped for short periods without affecting the average length of the optical cavity. The length of time for which control could be interrupted would depend on mechanical and thermal stability, but might well be longer than a minute. Alternatively the frequency modulation could be eliminated by using a second maser, not being vibrated, which was controlled relatively to the first using their beat frequency as the control signal.

Experience over a period of several months with the simple control system described has shown that a reproducibility of wave-length to a few parts in 10^8 can be readily achieved with a particular maser system. Because the wave-length is affected by the conditions of operation, the system is not suitable at present for a primary wave-length standard. If, however, its wave-length is occasionally verified against the krypton-86 standard, then the light from a controlled maser forms an excellent secondary standard suitable for precision interferometric measurements of length over long paths.

We thank the Services Electronics Research Laboratory for providing the optical components of the maser. The work described here has been carried out as part of the research programme of the National Physical Laboratory and is the subject of patent applications. This article is published by permission of the Director of the Laboratory.

SHAPE, INTENSITY AND PRESSURE BROADENING OF THE 2·53-MILLIMETRE WAVE-LENGTH OXYGEN ABSORPTION LINE

By A. E. SCHULZE and C. W. TOLBERT

Electrical Engineering Research Laboratory, University of Texas, Austin

INCREASING demands for broad-band-width communications channels have led to the investigation of propagation characteristics through the atmosphere of the Earth of signals in the 10^{11}–10^{12} c/s frequency range. The resonant absorption of energy at selected wave-lengths by oxygen and water vapour causes the atmosphere to be partially opaque to the transmission of signals in this region of the electromagnetic spectrum.

The microwave absorption spectrum of molecular oxygen consists of many fine-structure spectral lines. The absorption is usually represented by approximately 25 major lines in the 5-mm region and a single isolated line in the region of 2·5-mm wave-length.

Spectroscopists have been concerned primarily with the measurements of oxygen line-centre frequencies, however, propagation of signals in the atmosphere in the vicinity of the line frequencies requires a knowledge of the shape, intensity and pressure broadening associated with the lines. Although sufficiently monochromatic signal sources have been available for several years to allow the measurement of the characteristics of the 2·53-mm line, the difficulties of measuring the low intensity of absorption because of the magnetic coupling of energy to the oxygen molecules, together with the limited interest of spectroscopists in pressure broadening, have delayed accurate investigations of the line shape and intensity.

Although several mathematical models have been proposed to describe the shape and intensity of a spectral line, the Van Vleck–Weisskopf equation[1] has been found to describe best pressure broadening in the microwave region. In this theory the period of oscillation of the incident electromagnetic energy is assumed to be much longer than the mean duration of a molecular collision. In the microwave and longer wave-length regions, this condition is approximately true, however, the approximation becomes worse as the frequency of the incident electromagnetic energy used to observe the transition is increased.

The Van Vleck–Weisskopf theory also assumes that intermolecular collisions constitute a random interruption of the phase of a molecular harmonic oscillator, such that after collision each molecule assumes an independent phase. The mathematical expression for the line shape involves the half-intensity, half-width ($\Delta\nu$) of the line which is treated as a semi-empirical parameter predicted to be a direct linear function of the gas pressure. The peak intensity of the line is predicted to remain constant over the domain of pressure broadening. There is a dearth of accurate measurements of line shape and intensity over a wide range of pressures for comparison with the mathematical model.

The object of the investigation reported here was to measure the shape and intensity of the 2·53-mm wave-length oxygen absorption line over a range of pressures corresponding to elevations in the atmosphere from sea-level to approximately 170,000 ft. The measurements were to ascertain the absorption due to dry oxygen alone, with provisions for extrapolating the data to fit atmospheric absorption due to a mixture of dry atmospheric gases.

A 500-ft long, 6-in diameter, outer copper conductor of a coaxial line was used as the absorption cell. Two glass-supported 'Teflon' windows, experimentally found to approximate an integral multiple of a half-wave-length thick, were used to seal the cell. Transmission through the cell was accomplished by propagating a wave from a conical horn antenna such that it was incident on the dielectric window essentially as a plane wave. The coherent signal between 114 Gc/s and 123 Gc/s used for the measurements was derived from a crystal harmonic generator excited by a variable-frequency Raytheon *QKK* 864 reflex klystron.

The power lost in the free-space coupling of the transmitting and receiving antennæ to the absorption cell, together with the relatively low level of 118-Gc/s signal output from the crystal harmonic generator, required the

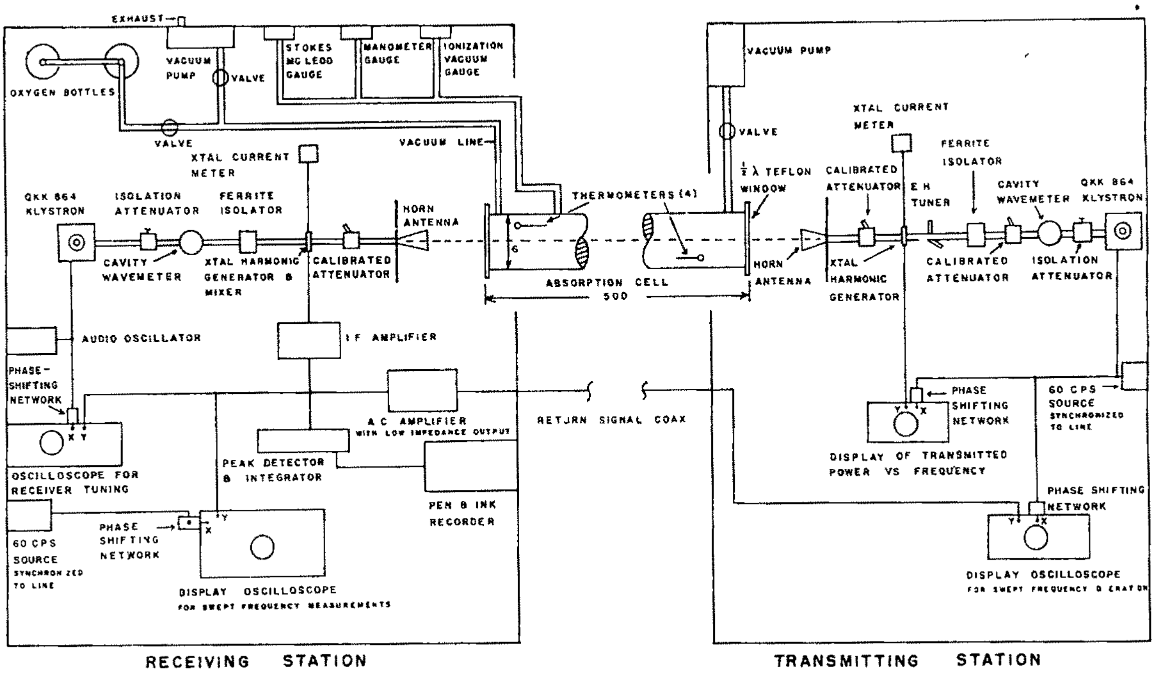

Fig. 1. Block diagram of the microwave spectrometer used to measure the 2·53-mm oxygen absorption line

use of heterodyne detection techniques. The configuration of the absorption cell made Zeeman modulation impractical.

The spectrometer (Fig. 1) is a data-sampling system in which the superheterodyne receiver samples the transmitted signal at an audio rate.

Two types of measuring techniques were necessary to evaluate the line shape and intensity over the wide dynamic range of values associated with gas pressures between 0·5 mm and 760 mm mercury.

Between pressures of 0·5 mm and 4·0 mm mercury, where the significant features of the line could be encompassed by frequency modulating the signal source, swept-frequency measurements were taken. For these measurements, the transmitter was modulated with a 60 c/s sinusoidal signal synchronized to the primary 115-V a.c. power line frequency. A similar signal with adjusted phase was used to scan the X-axis of an oscilloscope, while the output of the intermediate frequency (IF) amplifier of the receiver was displayed on the Y-axis of the oscilloscope. Thus, the X-axis was a frequency scale which was calibrated by a knowledge of the bandpass of the narrow-band IF amplifier. The Y-axis was a signal-level scale which was calibrated by the use of the calibrated attenuator at the receiver.

Swept-frequency measurements of the peak intensity and the width of the absorption line were taken by photographing the signal-level versus frequency data displayed on the oscilloscope at pressures of 0·5, 1·0, 1·5, 2·0, 2·5, 3·0, 3·5, 4·0, 4·5, 5·0 and 6·0 mm mercury.

Between the pressures of 4 and 760 mm mercury, the width of the line required the use of a fixed-frequency measuring technique. For these measurements, the frequency of the transmitter was set to a selected fixed-frequency while the pressure of the gas within the absorption cell was varied.

Fixed-frequency measurements of oxygen attenuation at pressures of 8, 15, 30, 60, 100, 200, 300, 400, 500, 600, 700 and 760 mm mercury were taken at frequencies of 30, 60, 120, 240, 480, 1,000, 2,000 and 4,000 Mc/s on both sides of the line-centre frequency. Measurements were taken by evacuating the absorption cell to a pressure sufficiently low to provide an unmeasurable amount of oxygen absorption at the pre-set frequency, calibrating the chart of a pen and ink recorder with the calibrated attenuator, and injecting oxygen into the cell while the attenuation as a function of pressure was recorded. The 30-Mc/s centre frequency of the narrow-band IF amplifier was utilized to precisely set the desired transmitter frequencies between line-centre and 1,000 Mc/s on either side of line-centre.

To reduce each measured value to the equivalent value at a common temperature, a temperature-adjustment coefficient explicit in the Van Vleck–Weisskopf theoretical equation was applied to the data. In this manner, the data were adjusted to a common temperature of 300° K, the mean temperature at which measurements were taken.

The Van Vleck–Weisskopf shape factor was first assumed adequately to describe the shape of this pressure-broadened spectral line, and the value of the line-centre frequency was taken to be 118·745 Gc/s as measured by Anderson, Johnson and Gordy[2]. It was then necessary to determine the required constants of the shape factor in order best to describe the experimental data over the entire range of pressures of 8–760 mm mercury. The assumed expression for attenuation is as follows:

$$\gamma = K_0\nu^2\left[\frac{\Delta\nu}{(\nu_0-\nu)^2+(\Delta\nu)^2}+\frac{\Delta\nu}{(\nu_0+\nu)^2+(\Delta\nu)^2}\right]$$

where γ = attenuation in db/km for 100 per cent oxygen at 300° K, ν_0 = line-centre frequency in Gc/s (118·745 Gc/s), ν = frequency in Gc/s, K_0 = a constant for a given pressure and temperature (related to the peak intensity and $\Delta\nu$ by $K_0 \cong \frac{\gamma\text{ peak }\Delta\nu}{\nu_0{}^2}$), $K_0 = C\frac{P}{T^3}$ (ref. 3).

A digital computer was used to determine K_0 and $\Delta\nu$ for the best fit of this Van Vleck–Weisskopf equation to the experimental data at all measured pressures. Thus, the computed curves accomplished the necessary averaging and weighting of the data.

Fig. 2 shows an example of the calculated curves representing the best fit to the experimental data of the Van Vleck–Weisskopf line shape. The equation for the calculated curves is:

$$\gamma = 24{\cdot}9\,\frac{P}{T^3}\,\nu^2\left[\frac{\Delta\nu}{(118{\cdot}745-\nu)^2+(\Delta\nu)^2}+\frac{\Delta\nu}{(118{\cdot}745+\Delta\nu)^2+(\Delta\nu)^2}\right]$$

The curves (Fig. 2) are within the root mean square experimental accuracy of the data.

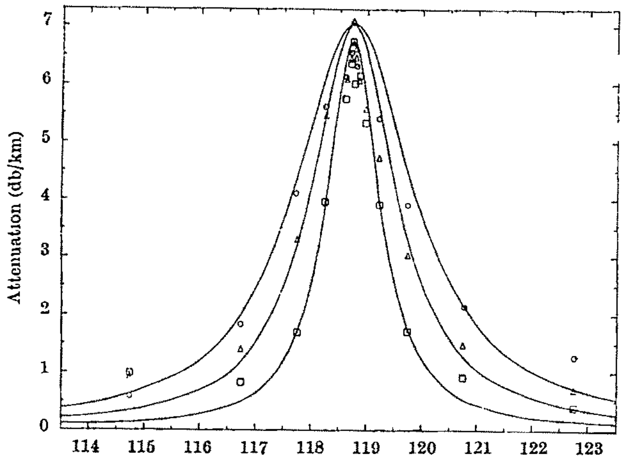

Fig 2 Attenuation versus frequency for pressures of 700 (○), 500 (△) and 300 (□) mm mercury Oxygen 100 per cent at 300° K

The discrepancies existing between the average of the measured values and the calculated curves are associated with the measuring uncertainty, the inadequacy of the line shape factor, and the assumed temperature-adjustment coefficients

It is probable that the Van Vleck–Weisskopf shape factor does not exactly describe the line shape of this oxygen absorption line[1,3] This is evident from the failure of the Van Vleck–Weisskopf line shape factor to describe exactly the experimental points near line-centre frequency and the wings of the absorption line If the shape factor is calculated to fit the measured values of attenuation near line-centre frequency, it fails to fit the wings, and vice versa Thus, the best description of the experimental data using the Van Vleck–Weisskopf shape factor represents a compromise between a description of the attenuation in the vicinity of the peak intensity and a description of the attenuation in the wings of the line

The curve of Δν versus pressure (Fig 3) was derived using the average value of Δν obtained from the calculated curves best describing the data The slope of this line is 1·90 $\frac{\text{Mc/s}}{\text{mm Hg}}$ for 100 per cent oxygen at 300° K The slope

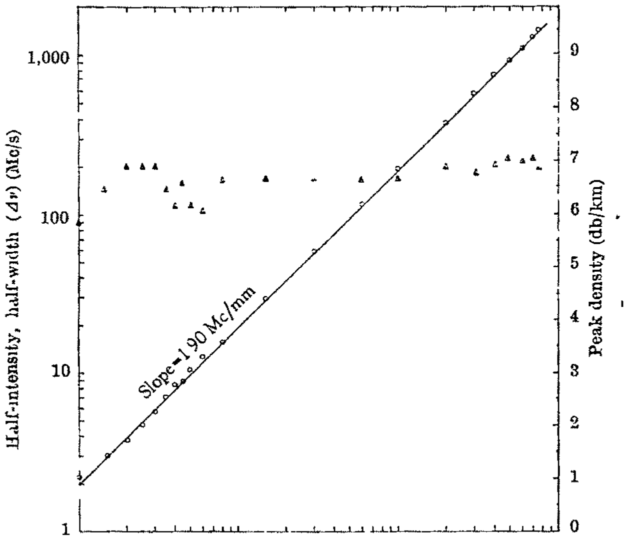

Fig 3 Half-width at half-intensity (○) and peak intensity (△) of the 2·53-mm wave-length oxygen absorption line versus pressure Oxygen 100 per cent at 300° K

of the Δν versus pressure curve obtained by the dynamic-frequency technique for a range of low pressures is 2·08 $\frac{\text{Mc/s}}{\text{mm Hg}}$ The difference between these two values is attributed to experimental uncertainty The mean of these two values, 1·99 $\frac{\text{Mc/s}}{\text{mm Hg}}$ at 300° K, is in excellent agreement with the value of 1·97 $\frac{\text{Mc/s}}{\text{mm Hg}}$ at 300° K measured by Hill and Gordy[4] It is also in good agreement with the theoretical value of 2·064 $\frac{\text{Mc/s}}{\text{mm Hg}}$ calculated by Artman and Gordon[5] The agreement of this measurement with atmospheric propagation measurements made by this Laboratory[6] supports the argument that nitrogen–oxygen collisions and oxygen–oxygen collisions cause approximately an equivalent amount of pressure broadening[3]

Although very few measurements have been made of the peak intensity of this oxygen absorption line, atmospheric propagation measurements by this Laboratory at frequencies below line-centre frequency indicate a peak intensity of 1·71 db/km for air at 291° K and 740 mm mercury[6] Assuming the atmospheric gases to be composed of 21 per cent oxygen, this value yields 7·66 db/km for the peak intensity of the line in 100 per cent oxygen at 300° K From Fig 3, the peak intensity at this pressure is approximately 7·0 db/km The difference between these two values is within the combined experimental uncertainty of the two measurements

Measurements taken with this spectrometer using air show the air/oxygen broadening ratio to be approximately unity and the air/oxygen attenuation intensity ratio to be approximately 0·21 Thus, the approximate horizontal attenuation in the atmosphere due to oxygen absorption alone can be obtained by multiplying the values of attenuation due to 100 per cent oxygen by 0·21

In order better to evaluate the line shape, all data were converted to the equivalent values at 760 mm mercury This conversion was accomplished by assuming that the line expands linearly with increasing pressure about the line-centre frequency For constant values of attenuation, this assumption may be expressed as

$$\left.\frac{f_1}{P_1}\right|_{\gamma = a} = \left.\frac{f_2}{P_2}\right|_{\gamma = a}$$

where f_1 and f_2 are the frequency deviations from line-centre for which $\gamma = a$, a is a constant, and P_1 and P_2 are the pressures corresponding to f_1 and f_2, respectively This condition is also explicit in the Van Vleck–Weisskopf line shape equations for small frequency deviations from line-centre

The result of the conversion of these data by the linear transformation is shown in Fig 4 Although the measured line shape is approximately—but not exactly—described by the Van Vleck–Weisskopf shape factor, the measurements are better described by modifying the exponents of the numerator and denominator of the shape function

At a pressure corresponding to sea-level, 760 mm mercury, all the data converted to this equivalent pressure by the linear transformation are more accurately described by

$$\gamma = 6·69 \times 10^{-4}\nu^2 \left[\frac{(\Delta\nu)^{0·65}}{(|\nu_0 - \nu|)^{1·65} + (\Delta\nu)^{1·65}}\right]$$

where $\Delta\nu$ = 1·45 Gc/s for 100 per cent oxygen at 300° K This modification is of the general type required to partially compensate for the fact that the reciprocal of the average time between intermolecular collisions is less than the average of the reciprocals of these times

Although the Van Vleck–Weisskopf shape factor does not exactly describe the shape of the 2·53-mm wave-

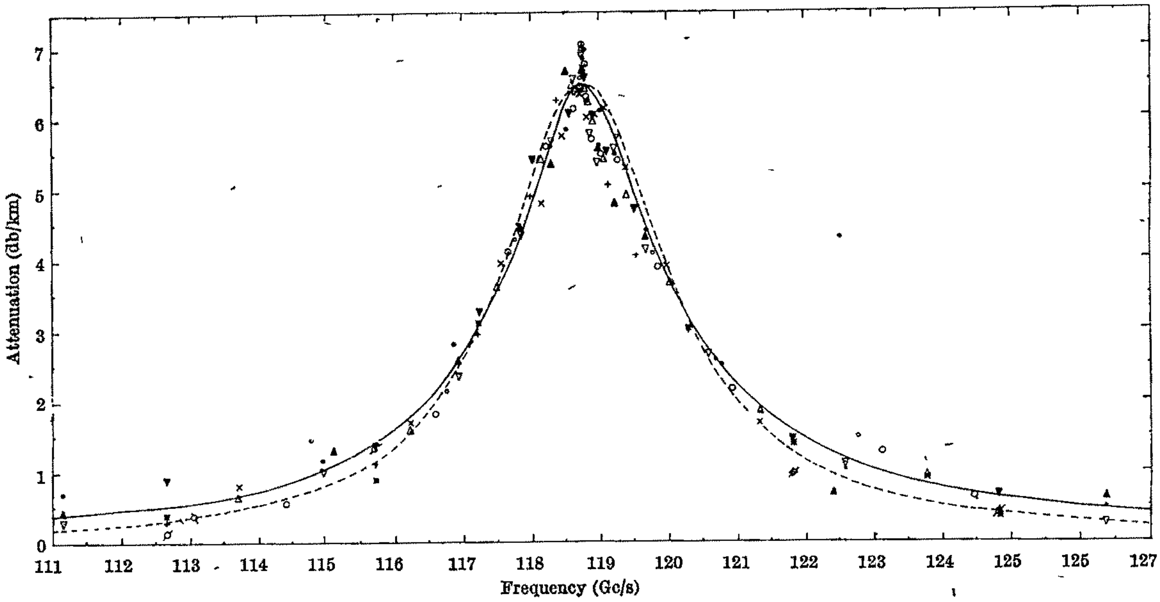

Fig 4 Measured values of attenuation converted to a common pressure of 760 mm mercury by the use of a linear transformation in frequency ∘, 760 mm, ○, 700 mm, △, 600 mm, ▼, 500 mm, ●, 400 mm, ×, 300 mm, ▽, 200 mm, ▲, 100 mm, +, 60 mm, ★, 30 mm, ↗o↗, 15 mm, ↘o↘, 8 mm 100 per cent oxygen at 300° K – – –, Van Vleck–Weisskopf line shape, ——, modified line shape

length oxygen absorption line, it is a good approximation of the shape except in the far wings A better fit of the wings is obtained by modifying the exponents of the numerator and denominator of the shape factor

The Van Vleck–Weisskopf shape of the absorption line as measured at pressures of 8–760 mm mercury is given by the equation

$$\gamma = 24{\cdot}9\,\frac{P}{T^3}\,\nu^2\left[\frac{\Delta\nu}{(118{\cdot}745-\nu)^2+(\Delta\nu)^2}+\frac{\Delta\nu}{(118{\cdot}745+\nu)^2+(\Delta\nu)^2}\right]$$

for 100 per cent oxygen near 300° K.

The measured line-width parameter, $\Delta\nu$, is best described by

$$\frac{\Delta\nu}{P} = 2{\cdot}08\ \frac{\text{Mc/s}}{\text{mm Hg}}\ \text{for } P \leqslant 4 \text{ mm Hg}$$

$$\frac{\Delta\nu}{P} = 1{\cdot}90\ \frac{\text{Mc/s}}{\text{mm Hg}}\ \text{for } 4 \text{ mm Hg} \leqslant P\ L\ 760 \text{ mm Hg}$$

$$\frac{\Delta\nu}{c} = 0{\cdot}481 \text{ cm}^{-1}\text{/atmosphere}$$

for 100 per cent oxygen at 300° K

The measured peak absorption of energy by 100 per cent oxygen at 300° K increases very slightly with pressure from a value of 6·5 db/km at 3·5 mm mercury to a value of 7·0 db/km at 500–700 mm mercury The increase in the peak intensity is due almost entirely to the wings of the pressure-broadened 5-mm wave-length oxygen line complex

RADIOACTIVE DECAY OF ANTIMONY-124

By A. SESHAGIRI RAO, V. LAKSHMINARAYANA and PROF. SWAMI JNANANANDA

Department of Nuclear Physics, Andhra University, Waltair, India

THE importance and usefulness of a Compton scintillation spectrometer for the investigation of complex γ-ray spectra were first pointed out by Hofstadter and McIntyre[1] A Compton scintillation spectrometer suppresses the Compton continuum thus enabling the low-intensity, low-energy photon peaks, previously masked by the high-intensity high-energy components, to appear prominently in the spectrum Experimental, as well as theoretical, investigations of the efficiency of a fast–slow Compton scintillation spectrometer were made by Howland, Scofield and Taylor[2] They

Table 1. γ-LINES OCCURRING IN THE DECAY OF ANTIMONY-124

Serial number	Recoil electron energy (keV)	Corresponding photon energy (keV)	Values of energy (ref. 4) (keV)
1	415	603	603 (632, 646)
2	520	719	714, 723 ± 1
3	750	964	970 ± 2
4	830	1,047	1,047 ± 3
5	1,070	1,296	1,298 ± 4
6	1,160	1,388	1,326 ± 4, 1,361 ± 5 1,370 ± 4
7	1,280	1,512	1,450 ± 14, 1,505 ± 15 1,540 ± 16
8	1,455	1,691	1,692 ± 2
9	1,650	1,889	1,900 ± 20
10	1,850	2,092	2,088 ± 4
11	2,030	2,274	2,260 ± 15

investigated the variation of efficiency of their experimental arrangement as a function of incident photon energy. Mono-energetic sources were used in their work, and the experimental results agree with theoretical estimates. The fast–slow Compton spectrometer has since become an important tool for accurate spectroscopic work, and hence was used in the investigation reported here to examine the complicated decay of the radioactive isotope antimony-124.

The decay scheme of antimony-124 was extensively examined and the fairly well-established features were summarized in the work of Dzhelepov *et al.*[3] Later work by Girgis *et al.*[4], using a conventional scintillation spectrometer, pointed out the necessity to introduce three new levels at 1,350, 1,900 and 2,865 keV, to accommodate the new γ-lines detected in their work. Recent work carried out in this laboratory[5], utilizing an electronic summing spectrometer, confirmed the three new levels introduced. However, the 2,260-keV line was shown to be the cross-over transition from the 2,295 keV-level and not from the 2,865 keV-level, as inferred by the complete absence of the cascade 2,260–603 keV in the sum-coincidence spectrum, when the sum gate was set at 2,865 keV. In the present investigation the decay of antimony-124 was examined with a fast–slow type of Compton scintillation spectrometer.

A Compton scintillation spectrometer comprising a 1.5 in. × 1 in. sodium iodide (Tl) crystal as the direct crystal and a 1.75 in. × 2 in. sodium iodide (Tl) crystal as the side crystal, both coupled to DuMont 6363 phototubes, was assembled. A fast–slow coincidence arrangement was made with an overall resolving time of about 120 mμsec. The fast coincidence circuit used was a modification of that reported by Green and Bell[6] and was operated with pulses derived from linear amplifiers following the photomultipliers. A geometrical arrangement similar to that of Davisson and Evans[7], with about 37′ as the semi-apex angle, was adopted, as shown in Fig. 1.

The antimony-124 source of strength about 10 mc. is introduced into the source-holder, and the singles spectrum as observed in the direct spectrometer is first recorded and shown in Fig. 2. In addition to the strong lines reported earlier, indications of peaks at 2,260 keV and 1,900 keV are obtained in the spectrum. The side spectrometer is next used to gate the main spectrometer with a channel width between 170 and 250 keV. The resultant coincidence spectrum is recorded and shown in Figs. 3*a* and 3*b*. The high-energy part of the spectrum is recorded in a greater detail by adjusting the gain of the amplifier and bringing the spectrum to a convenient level. The energies of the prominent peaks are estimated, and from these recoil electron energies the corresponding photon energies are computed and given in Table 1, along with the energies reported by Girgis *et al.*

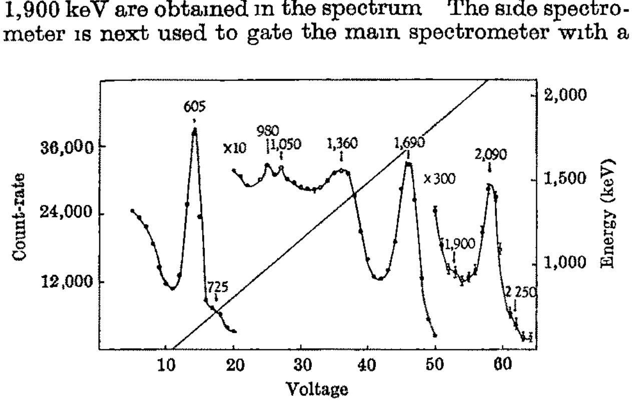

Fig. 2. Singles spectrum of antimony-124

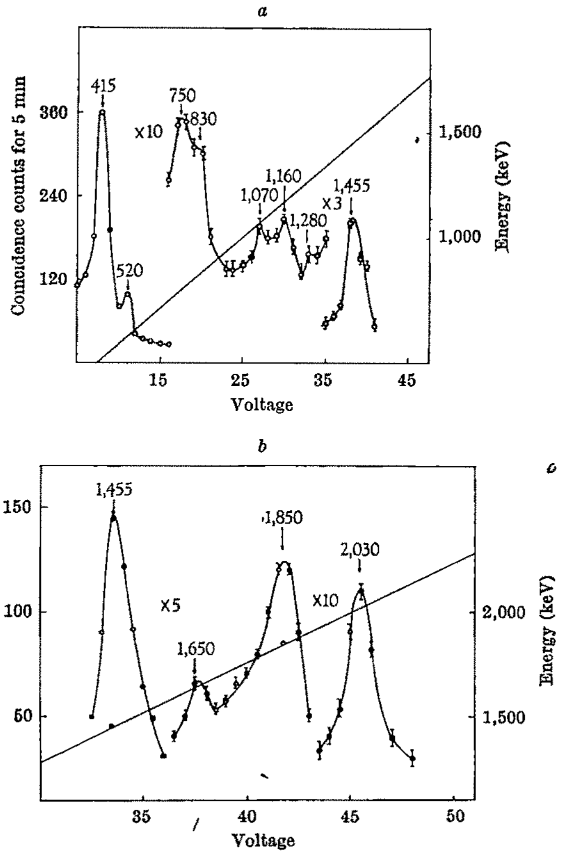

Fig. 3*a*, Coincidence recoil electron energy spectrum of antimony-124 (low-energy portion); 3*b*, coincidence recoil electron energy spectrum of antimony-124 (high-energy portion)

It can be seen from Table 1 that the present γ-lines at 603, 719, 1,388 and 1,512 keV are composite. Because of the small intensities of the closely lying energy components they could not be separated in the present work. In all other cases, the agreement between the present values of energy and those of Girgis *et al.* is satisfactory. Clear indications of peaks corresponding to 1,900 keV and 2,260 keV are observed supporting the existence of these two lines in the decay of antimony-124 as proposed by Girgis *et al.* Although the present work supports the existence of the new lines at 1,900 and 2,260 keV, it is not possible to fix their positions in the level diagram based on the results of this work. Most of the lines occurring in the decay of antimony-124 and not appearing in the singles spectrum could be recorded in the coincidence spectrum because of the Compton suppression.

We thank the Department of Atomic Energy, Government of India, for sponsoring this scheme of work in our laboratory and for awarding a senior scientific assistantship to one of us (A. S. R.).

A MECHANISM FOR THE DIRECT ACTION OF IONIZING RADIATIONS

By Dr REINIER BRAAMS

Department of Radiobiophysics, University of Utrecht, Bijlhouwerstraat 6, Utrecht, The Netherlands

EXAMINATION of the effect of ionizing radiations on dry proteins[1-4] can be considered of importance for an explanation of the mechanism through which the absorption of radiation energy leads to chemical changes in proteins In the past twenty years a number of interesting experimental results have been reported, but there appears to be no model for the action of ionizing radiation on proteins which explains more than a few of the known facts

From recent investigations with quantitative electron spin resonance spectroscopy[5-10], it has become evident that a close relation exists between protein damage and the behaviour of protein radicals Of these correlations the following are of outstanding importance

(1) The radical yields in amino-acids, peptides and proteins are of the same order of magnitude[5-9] as the G-values for loss of amino-acid residues in irradiated proteins[11-13]

(2) Radical yields for irradiations at 77° K are lower[7,9] than for irradiations at about 295° K This parallels the decrease in radiation sensitivity of enzymes when the material is irradiated at liquid nitrogen temperature instead of at room temperature[2,3,14,15]

(3) Certain SH compounds that can partly protect proteins[16-18] against radiation inactivation when present with the protein in the dry state during irradiation can also receive unpaired spins which initially were induced outside the SH moiety[10,18,19]

(4) Interaction of radicals in irradiated protein with NO leads to changes in the observed radical pattern and strength, and to changes in the degree of inactivation of the irradiated protein[20]

If one accepts the importance of radicals as chemical intermediates, then, with the aid of proposals by Voevodsky[21] and Varshavskii *et al* [22], a scheme can be developed which will explain a number of effects observed in proteins and which can be extended to nucleic acids and to organic material in general

The first step in this chemical reaction scheme is the dissociation of the irradiated macromolecule into a large and a small radical fragment

$$MR_i \rightarrow M + R_i \qquad (1)$$

Here MR_i represents a protein macromolecule composed of a main chain with many different side-chains R_i, M is a relatively stable radical state of the macromolecule and $\dot{R}_i$ is a small diffusible radical Recombination of the two radicals can occur, but does not necessarily lead to repair since about 4 eV (approx 100 kcal/mole) must be dissipated without changing the configuration of the protein M is usually stable at cryogenic temperatures but can change into a different radical on raising the temperature[9,10,23]

Rowlands and Whiffen have collected from the literature the structures assigned to 61 radicals obtained by irradiation of organic compounds[24] In 43 cases the radical appears to have been formed by breakage of the C—H bond and the removal of H It seems therefore that in many cases the radical R_i will be atomic hydrogen

$\dot{R}_i$ is very potent chemically, especially if it is in the excited state[25] For H to react with other side-chains an activation energy of about 5–9 kcal/mole[26,27] is needed and this energy will often be available If only molecules of the MR_n type are present $\dot{R}_i$ can react with MR_n

$$R_i + MR_n \rightarrow M + R_iR_n \qquad (2a)$$

In the special case that R_i is atomic hydrogen the reaction is

$$H + MR_n \rightarrow M + R_nH \qquad (2b)$$

The reactions (2a) and (2b) could proceed also in a backward direction as proposed by Varshavskii *et al* [22] to explain the chemical migration of free radical sites through semi-crystalline polyethylene The forward reactions result in the formation of another protein radical, and a small molecule which could either react with a protein radical or escape as gas They will proceed fast when R_i carries enough energy to overcome the activation barrier After $\dot{R}_i$ has become thermal (at room temperature) the reactions will be much slowed down but can still proceed at a measurable rate, especially when the entropy of activation is low

In polymers with a small number of possible side-groups R_i, only a few different types of gas molecules will be found In polyethylene most of the gas consists of molecular hydrogen, while in polydimethyl–siloxane hydrogen, methane and small amounts of ethanol were found[21] In proteins the situation could be more complex, but apparently reactions (1) and (2) occur with preference at the site of the glycine residue In experiments designed to detect the evolution of molecular hydrogen the production of gas (partly consisting of H_2) could be observed during the irradiation of amino-acids and proteins[28]

The thermal annihilation of radicals in irradiated amino-acids and proteins at about 100° C suggests that M can react with its environment It has been observed[29] that during thermal annealing of radicals in alanine and in protein, gas is produced This leads to the suggestion that reactions of the following type can occur

$$M + MR_i \rightarrow MM + R_i \qquad (3a)$$

$$M + MR_i \rightarrow M_1 + M_2 + \dot{R}_i \qquad (3b)$$

Reaction (3a) represents a cross-linking between 2 macromolecules, whereas reaction (3b) leads to two changed macromolecules M_1 and M_2 Both reactions produce a small radical that undergoes further reaction and eventually appears as gas

If SH compounds are present in the dry material the radicals $\dot{R}_i$ can abstract an H-atom from RSH

$$\dot{R}_i + RSH \rightarrow RS + R_iH \qquad (4)$$

If sufficient RSH is present and when the affinity of R_i to RSH is high, reaction (4) will compete with (2) and might even be favoured This results in protection in the dry state as has been observed by several authors[16,18,30] When reaction (4) completely dominates reaction (2) the radiation sensitivity will appear reduced to about 50 per cent of the sensitivity of the protein in the absence of protective compounds This is the order of magnitude actually found for enzymes[16-18,30,31] and for bacteriophage[32] when irradiated in the dry state in vacuum

Oxygen, when present, will compete with the protein for reaction with $\dot{R}_i$ to form peroxy radicals[31,33] that will peroxidize the protein to similar damage as with irradiation in vacuum and subsequent exposure to oxygen[20] If, however, protective compounds are present, the oxygen will compete with the protective agent for $\dot{R}_i$ to form peroxy radicals, reducing the protective effect of SH compounds in the presence of oxygen, as has been observed by Butler and Robins[30,31] for trypsin

Several observed experimental facts appear to be in agreement with the proposed model

(1) The inactivation curves of enzymes irradiated in the dry state are exponential. The number of interactions N leading to reaction (1) will be proportional ($N = a D$) with the radiation dose D. The average number of enzyme molecules affected by one interaction through reactions (1–4) will be q. This number will depend on the environmental conditions. The probability that an affected molecule will be inactivated is p, p depending on conditions before or during assay of the enzyme activity. The average number of inactivated molecules per interaction will then be pq. The activity remaining after a dose D can now be given by

$$A(D) = A\,e^{-pqaD}$$

(2) The slope of the inactivation curves plotted on semi-log paper is dependent on temperature. When irradiations are carried out at different temperatures, the inactivation curves are still exponential but with different slopes. If reaction (1) is dependent on temperature the probability q will also be dependent on temperature. From the available data[34], it appears that q is an exponential function of the reciprocal value of T in the temperature range 70°–300° K.

(3) In the presence of SH compounds the radiation sensitivity of enzymes is reduced to about half the sensitivity without protecting agents present. At high concentrations of the protective agent the protection factor[17,31] can become slightly higher than two. This occurs when, after interaction with ionizing particles, the SH compounds themselves are contributing hydrogen atoms for reaction with protein radicals. Such a reaction could lead to restoration of the original chemical composition of the protein molecules. The probability that such a restoration occurs without changes in the native configuration of the protein must be considered small since the protection factor in the dry state is usually in the neighbourhood of 2–3.

(4) The frequently observed transfer of spins to SH compounds in mixtures of proteins or amino-acids with SH compounds is diffusion controlled[8].

(5) The protection with SH compounds is also achieved when irradiations are carried out at liquid nitrogen temperature[35] since reactions with $\dot{R}_i$ can start when the temperature of the sample is brought back to room temperature. The fact that the protection factor for irradiations at low temperature is nearly the same as for radiation at room temperature seems to indicate that excitation of R_i is not a necessary condition for reaction with protein.

(6) When oxygen is present during irradiation both the protein radicals and $\dot{R}_i$ will react with oxygen. The effect to the protein could be slightly different from the changes caused by irradiation in vacuum and subsequent exposure to oxygen before dissolution. Hunt *et al.*[20] find that for RNase the radiation sensitivity for exposure to oxygen during irradiation is about 1·3 times the sensitivity for irradiation in vacuum with subsequent exposure to oxygen.

(7) When protective compounds are present during an irradiation in oxygen, the protective effect cannot be exerted and an oxygen effect becomes apparent[30,31].

(8) At very high LET values, the rise in temperature in the centre of the track can be several thousands of degrees. Atomic hydrogen and other small radicals that have been formed will not easily combine or recombine in the region of high temperature. Because of the high pressure and temperature they will diffuse farther away from the central core of the track at low LET. The mechanism of energy transfer needed to explain the enlarged radiation cross-sections for enzymes irradiated with fully ionized carbon or oxygen nuclei[36] then simply is the diffusion of hot small radicals.

(9) Since the processes in the region of the track of particles with very high LET will be governed by the transient high temperature with values of thousands of degrees, the effects will not be influenced much by a change in the ambient temperature of about 200° C. For these particles the radiation sensitivity of enzymes should not depend much on the temperature at which radiation is carried out. Brustad[36] has actually observed this for trypsin, DNase and lysozyme.

(10) In the region of high temperature around the track of a high LET particle, scavenging of the small radicals $\dot{R}_i$ by SH compounds will not be effective, and the radicals will be able to diffuse away from the central core. In this core therefore no protection can be expected. Outside the core around the δ-ray tracks interaction with SH presumably still could occur. The overall effect of the presence of SH compounds thus results in a small protective effect. Brustad[36] has observed that trypsin is not protected by cysteine when irradiated with 115-MeV carbon nuclei. It appears that better agreement between theory and experiment can only be expected after the theory has been more refined and experimental data have become more abundant.

(11) When protein is surrounded by an excess of chemically different material the radiation effects in the protein fraction will be influenced by the radical production in the surrounding material and by the nature of these radicals. Sensitization can be expected to occur when the surrounding substances produce more, and more aggressive, radicals than proteins. Sensitization of enzymes in the presence of excess foreign material has actually been observed for invertase and RNase in acetate and in sucrose for 4-MeV deuterons[16], for trypsin in dextran or in ribose after irradiation with 115-MeV carbon-ions[36] and for trypsin exposed to fast electrons in the presence of magnesium salts[31].

(12) The fraction of molecules which show thermolability[37] is independent of the presence of protective compounds[36], indicating that in the presence of protective agents only the number of events damaging to the protein-molecules are reduced but that the nature of the damage has not been changed.

(13) The fraction of molecules which show thermolability is the same for irradiations performed at room temperature or at liquid nitrogen temperature[38], indicating again that by decreasing the temperature only the number of damaging events (the formation of a protein radical) is reduced but not their character.

(14) The presence of SH does not prevent the formation of free radicals in protein, a fact observed and explicitly stated by Henriksen *et al.*[10]

(15) A strongly reducing radical such as H could be expected to react with the disulphide bridge frequently present in proteins. Gordy *et al.*[39] have observed that in proteins containing –SS– linkages a cystine-like radical pattern is often found. If the reaction proceeds in the following way

$$\mathrm{H} + R_1-\mathrm{S}-\mathrm{S}-R_2 \rightarrow R_1-\mathrm{S}-\mathrm{H} + R_2-\mathrm{S}$$

breakage of the disulphide link would occur. This has been observed by Satlow and Zahn[40] in irradiated wool. After oxygen is admitted to the R–S radical this would react and oxidize the sulphur containing residue. After hydrolysis of irradiated wool an increase in the cysteic acid concentration has been found by Fritze *et al.*[41]

The model proposed here leads to a somewhat similar overall reaction as the hypothesis recently forwarded by Alexander and Ormerod[42,43]. The essential differences are:

(1) Real protection is possible through a mechanism of radical scavenging, similar to the mechanism now widely accepted for protection against the indirect effect. In the hypothesis by Alexander and Ormerod the important effect is a repair process.

(2) The protection is limited to a factor 2–3 in agreement with experimental observations, both on proteins and on bacteriophage. In the model by Alexander and Ormerod there are no reasons given why repair should not take place to a much higher degree than is actually observed.

(3) A simple chemical mechanism is given to explain the apparent interaction between the protein radical and the protective substance

The proposed model will have to be tested for quantitative agreement and for its capacity to produce valid predictions Especially the chemical reactions and their reaction kinetic constants will have to be specified in greater detail Some of the required experiments are being carried out and have yielded preliminary results which tend to support the hypotheses involved

If the model can be confirmed by more quantitative evidence, the original concepts of direct and indirect action will have to be re-defined the scavenging of small diffusible radicals not being restricted to the indirect action on compounds dissolved or suspended in water It appears, further, that with slight modifications the model can be extended to solutions and so provide a general theory for radiation effects in the condensed state

RADIOLYSIS OF ISOPRENOIDS

FROM U.S NAVAL RADIOLOGICAL DEFENSE LABORATORY, SAN FRANCISCO

2,6-Dimethyloctane

RADIOLYTIC yields of hydrogen and hydrocarbons through C_5 have been determined for 2,6-dimethyloctane, since this paraffin serves as a model for hydrogenated rubber

The 2,6-dimethyloctane was synthesized by a new route (The 2,6-dimethyloctane was synthesized by Chemicals Procurement Laboratories, 130th Street, College Point, New York) 2,6-Dimethyloctanol-8 (ref 1) was converted to the bromide, which was converted to the Grignard reagent, which was converted to the paraffin by treatment with water Specimens for radiolysis were distilled with a 20 *T P* Stedman column b p 157 0°–157 1° C (763 mm), n_D^{20} 1·4112, d^{20} 0 7291, M_D(calc) 48 38, M_D (found) 48 49 $C_{10}H_{22}$ requires C, 84 39, H, 15 61, found C, 84 18, H, 15 83

Specimens of approximately 30 ml were irradiated They were degassed by conventional vacuum techniques of freezing, pumping and trap-to-trap distillation, and then distilled into the irradiation cell which was sealed to one of the traps through a seal-off tube The cell was a 50-ml , quartz, round-bottomed flask fitted with a horizonal 'Pyrex' break-seal on the neck and a seal-off tube The cell was baked-out for 12 h with pumping while the degassed specimen remained frozen in a trap Since 2,6-dimethyloctane frequently ruptured cylindrical vessels during freezing–thawing operations, bulbous traps and irradiation cells were used

Gamma-irradiations were made at 22°–25° C with cobalt-60 Dosimetry was carried out with the ferrous sulphate dosimeter ($G(Fe^{3+}) = 15\ 5$) which duplicated the specimen in volume and geometry In calculating radiation yields (G = molecules/100 eV), the small correction due to the difference in electron density between specimen and dosimeter was made

Vapour-phase products in the cell were analysed with a Perkin–Elmer gas chromatograph, model 154 Irradiation cells were attached through the break-seal to a Toepler pump (300-ml capacity) joined to a 3 5-ml. loop suitably fitted with stopcocks to serve as the introductory unit of the gas chromatograph The cell gases were transferred to the loop with five operations of the Toepler pump and without freezing the solvent 50-ft dimethylsulpholane and diphenyl ether columns (20 wt per cent on 60–80 mesh firebrick) at 0° C were used with nitrogen as the carrier gas A thermistor detector and a flame ionization detector were used in series to measure hydrogen and hydrocarbons, respectively The chromatographic unit was calibrated for response to each of the radiolytic products found In some experiments for measuring hydrogen and methane only, it was convenient to use a 50-ft Linde molecular sieve column at 30° C, helium carrier gas and a thermistor detector In this case, the solvent was frozen with liquid nitrogen during each operation of the Toepler pump, and was thawed and re-frozen between each operation

Radiation yields were based on the analysis of the vapour-phase products in the cell and are averages of at least three irradiations Experiments showed that the Toepler pump removed at least 98 per cent of the hydrogen and methane from the liquid phase within the cell Undoubtedly, other hydrocarbons were not removed as efficiently because of solubility in the solvent, and their radiation yields are considered to be semi-quantitative

Table 1 gives the product yields and Fig 1 shows the linearity of the hydrogen gas and methane yields

Hardwick has proposed that the radiolysis of liquid paraffins proceeds via hydrogen atom and organic radical intermediates[2,3] It has not been necessary to invoke ion-molecule reactions to explain the products 'Hot' and thermal hydrogen atoms are produced by C—H bond scission The former abstract hydrogen on their first collision with a neighbour molecule to produce hydrogen gas The latter diffuse, react competitively with solvent and solute, and produce hydrogen gas by abstraction or

Table 1 RADIATION YIELDS (G) FOR 2,6-DIMETHYLOCTANE

Product	Molecules/100 eV
Hydrogen	3 32
Methane	0 28

self-combination In some cases, an activated hydrocarbon molecule may detach a hydrogen molecule, leaving a bi-radical or olefine Caged alkyl radicals from C—C bond scission recombine or disproportionate to a paraffin plus an olefine Freely diffusing alkyl radicals combine to produce paraffins or disproportionate According to Buckley and Szwarc[4], alkyl radicals may abstract hydrogen from hydrocarbons to produce paraffins

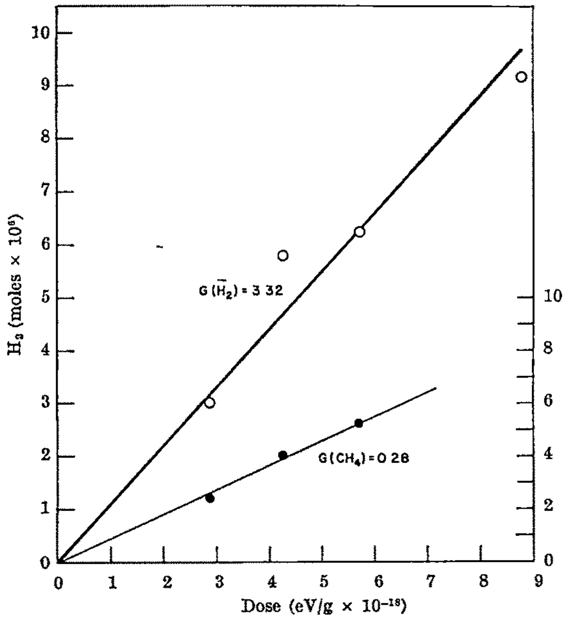

Fig 1 Yields of hydrogen and methane from 20 g of 2,6-dimethyloctane

On the basis of these views, direct routes are readily perceived to the following radiolytic products listed in Table 1 hydrogen, all paraffins except n-pentane, the olefines, ethylene, propylene, butene-1, butene-2, isobutylene and 2-methylbutene-1 For example, disproportionation accounts for the olefines On the other hand, the formation of the following trace products would seem to require some sequence of reactions n-pentane, pentene-1, pentene-2, 2-methylbutene-2, butadiene-1,3 and acetylene

2,6-Dimethyloctadiene-2,6 and Squalene

RADIOLYTIC yields of hydrogen and hydrocarbons through C_5 have been determined for 2,6-dimethyloctadiene-2,6 and squalene, since these olefines serve as models for natural rubber

2,6-Dimethyloctadiene-2,6 was prepared by the reduction of geraniol (purified through the calcium chloride complex[1]) with sodium in liquid ammonia (Geraniol and squalene were obtained from Distillation Products Industries, Rochester, New York) 1,500 ml of liquid ammonia was added to 462 g of geraniol in a 4-l Erlenmeyer flask fitted with a strong, efficient stirrer No precautions were taken to prevent condensation of moisture within the flask 54 g of sodium was added in small pieces to the stirred mixture for 1 h, during which time liquid ammonia was added occasionally to maintain the volume Additional sodium would not react The mixture was left for 0 5 h after which 1 5 l of ethanol was added in small amounts while the flask was kept in an ice bath Ethanol and ice were then added alternately and cautiously until any remaining sodium had reacted Finally, an excess of water was added, and the organic layer was extracted with ether The ether solution was washed with water until it was no longer alkaline, washed with saturated salt solution and dried with anhydrous sodium sulphate The ether was distilled away in a 3-l flask with a large distilling head, the flask was immersed in an oil bath ultimately raised to 100° C The residual mixture of 2,6-dimethyloctadiene-2,6 and geraniol was distilled *in vacuo* using a 3-l round-bottomed flask with a Claissen head, using an oil bath at 90°–110° C, and using slow distillation to avoid superheating A yield of 154 g (74 per cent) of crude 2,6-dimethyloctadiene-2,6 was obtained, b p 58°–60° C (13 5–14 mm)

Pure geraniol was recovered afterwards at 3–4 mm (b p 94° C) The diene gradually develops an acrid odour on exposure to air, but this may be prevented by storing it in the degassed state Specimens were distilled immediately before radiolysis with a 20 *T P* Stedman column, b p 166 0° C (774 mm), n_D^{20} 1 4491; d^{20} 0 7734, M_D (calc) 47 45, M_D (found) 47 49 $C_{10}H_{18}$ requires C, 86 85, H, 13 15, found C, 86 90, H, 13 15 The infrared spectrum of the purified diene agreed with that of Sheppard and Sutherland[2] It showed the absence of hydroxyl groups and the presence of less than 2 per cent of isopropenyl groups, $CH_2 = C(CH_3)$— The isopropenyl unsaturation occurs in the geraniol and cannot be removed therefrom by reported purification procedures A hypothetical specimen free from isopropenyl unsaturation would be expected to acquire the properties of isopropenyl unsaturation on irradiation due to the allylic resonance associated with one of the scission radicals $\dot{C}H_2C(CH_3) = CHCH_2CH_2C(CH_3) = CHCH_3 \longleftrightarrow CH_2 = C(CH_3)\dot{C}HCH_2CH_2C(CH_3) = CHCH_3$

Squalene (98 per cent) was purified immediately before radiolysis by passage through a silica-gel column, as described by Sax and Stross[3], and vacuum distillation $C_{30}H_{50}$ requires C, 87 73, H, 12 27, found C, 87 74, H, 12 25

As shown in the previous communication, specimens (20 g) were degassed in quartz cells, they were irradiated with γ-radiation from cobalt-60, and radiation yields

2-Methylbutene-1	1×10^{-2}	none

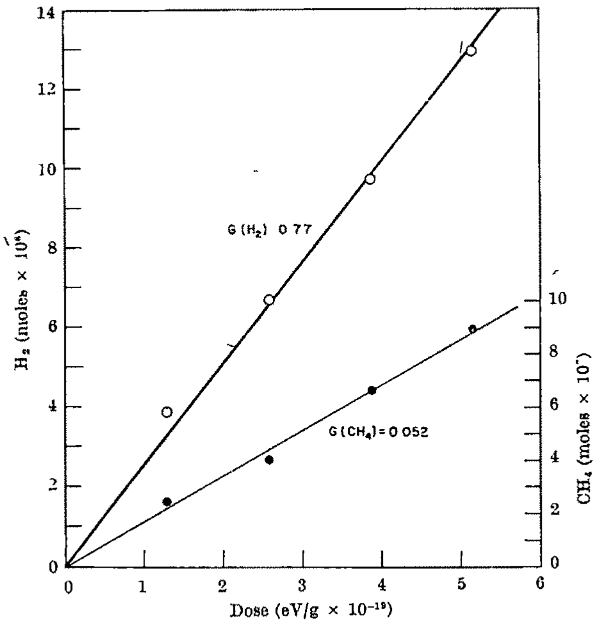

Fig 2 Yields of hydrogen and methane from 20 g of 2,6-dimethyloctadiene-2,6

were based on the gas chromatographic analysis of the vapour phase products in the cell This resulted in quantitative yields for hydrogen and methane and semi-quantitative yields for other hydrocarbons

Table 2 gives the product yields and Figs 2 and 3 show the linearity of the hydrogen gas and methane yields The product yields from squalene are generally less than those from 2,6-dimethyloctadiene-2,6

It is postulated that molecules of 2,6-dimethyloctadiene-2,6 and squalene undergo C—H and C—C bond scission on radiolysis to produce hydrogen, methyl and olefinic radicals These radicals are not expected to diffuse beyond a few molecules because of the great scavenging ability of the solvent, but are expected to react with adjacent and nearby molecules to produce stable products The reactions undoubtedly include addition of radicals to double bonds, abstraction of hydrogen, radical coupling, disproportionation, and rearrangement of unsaturation due to allylic resonance It does not seem reasonable to speculate on specific routes to observed products because of the complexity possible in the reactions

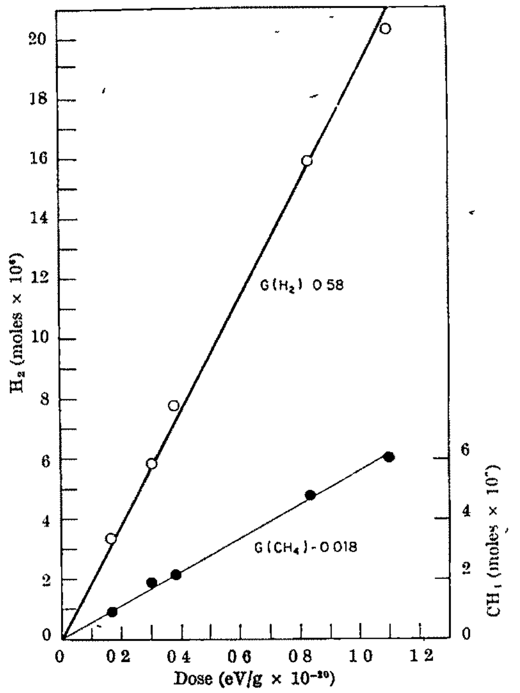

Fig 3 Yields of hydrogen and methane from 20 g of squalene

EFFECT OF X-IRRADIATION ON SUSCEPTIBILITY OF CELLS TO TRANSFORMATION BY POLYOMA VIRUS

By Prof MICHAEL STOKER

Medical Research Council Experimental Virus Research Unit, Institute of Virology, University of Glasgow

THE ability of polyoma virus to alter the hereditary properties of cells (polyoma transformation)[1,2] can be estimated quantitatively *in vitro* using the *BHK*21 line of hamster fibroblasts[3,4], and investigations can now be made on the conditions which affect the frequency of transformation following virus cell interaction

Since it is believed that X-irradiation predisposes to neoplasia, and some radiation-induced leukæmias in experimental animals are found to be transmissible[5], it was decided to examine the effect of X-rays on the sensitivity of *BHK*21 cells to transformation by polyoma virus

The tissue culture fluids and media, and the feeder layer cultures[6], the source and culture of *BHK*21 cells[3], the preparation of high titre virus stocks of a small plaque variant of polyoma virus[7] and the standard conditions for infection of *BHK*21 cells in suspension[4], have been described previously

The standard medium (designated *ETC*) consists of modified Eagle's medium with twice the normal content of amino-acids and vitamins. 10 per cent tryptose and 10 per cent unheated calf serum In all experiments, clone 13 of *BHK*21 cells was used after not more than 2 weeks' growth from a frozen stock at the thirtieth generation

Hamster cells, as well as mouse cells used for feeder layers, were irradiated as suspensions in *tris* buffer[8] with 2 5 per cent calf serum (afterwards called 'buffer') or as confluent monolayer cultures in medium A Watson-type Mobilix X-ray apparatus was used at 81 kV and 3 m amp delivering 4 1 r /sec in air The radiation was unfiltered and the target to cell distance was 12 7 cm The maximum depth of buffer or medium during the irradiation was 5 mm Following irradiation the suspended cells were centrifuged at 250*g* for 5 min and re-suspended in fresh buffer the intact monolayer cultures were washed with buffer

X-ray sensitivity of uninfected BHK21 *cells* The X-ray sensitivity of uninfected *BHK*21 cells was first determined Cells were exposed in suspension to various doses of

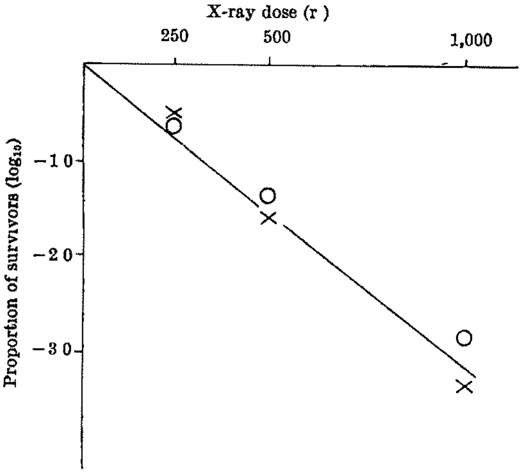

Fig 1 Sensitivity of normal and transformed *BHK*21 cells to X-irradiation Shows proportion of colony-forming cells surviving after irradiation compared with unirradiated controls
O, Normal, ×, transformed

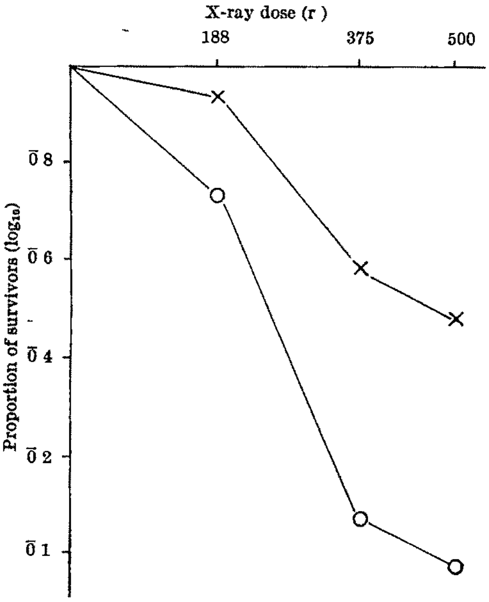

Fig 2 Effect of polyoma virus on irradiated normal *BHK*21 cells Cells were irradiated for various times and then exposed to virus Shows proportion of colony-forming cells compared to unirradiated controls
O, Normal, ×, transformed

irradiation and the numbers of surviving cells were determined by colony counts after plating on feeder layers of irradiated mouse cells For comparison a cloned, virus-free, line of polyoma transformed *BHK*21 cells was examined in the same way The results which are shown in Fig 1 do not reveal any significant difference in sensitivity between the normal and transformed cells No colonies with transformed or otherwise abnormal morphology were seen among about 10^4 survivors of normal cells after X-irradiation and conversely no normal colonies

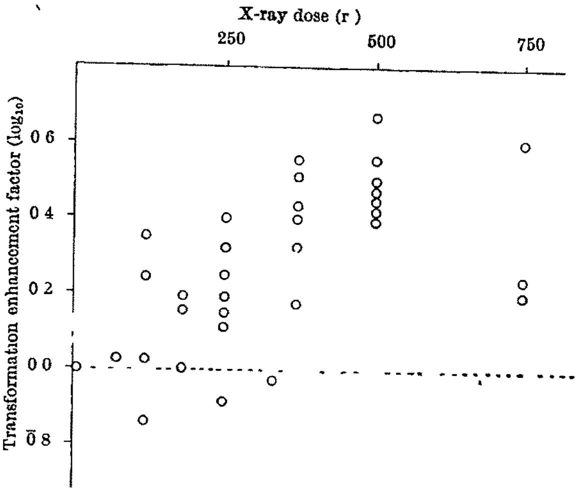

Fig 3 Effect of polyoma virus on irradiated normal *BHK*21 cells Pooled results of eight experiments showing enhancement in transformation frequency found after irradiation

$$\text{Enhancement factor} = \frac{\text{Proportion of transformed colonies from irradiated cells}}{\text{Proportion of transformed colonies from unirradiated cells}}$$

have been found among the surviving colonies of transformed cells

Effect of irradiation on frequency of transformation To investigate the effect of irradiation on subsequent polyoma transformation, batches of 1–2 million *BHK*21 cells were exposed in suspension to various doses of irradiation Equal numbers of cells (about one million) from each batch were infected in suspension with 10^8 plaque-forming units of polyoma virus and assayed for transformation by the standard method Table 1 gives the numbers of normal and transformed colonies which developed, and also the frequency of transformed colonies among total colonies (column 6) Fig 2 shows graphically the proportion of survivors which gave either normal or transformed colonies

It will be seen from Table 1 and Fig 2 that the irradiation reduced the number of viable cells giving normal colonies more rapidly than the number giving transformed colonies After 500 r and subsequent infection the proportion of normal viable cells had fallen from 46 to 4 4 per cent whereas the transformed viable cells only fell from 2 5 to 0 78 per cent This difference leads to an increase in the transformed colony frequency (column 6)

The increment in transformation produced by irradiation of the cells may be shown by the ratio of the transformed colony frequency after irradiation compared to the frequency in the unirradiated controls This will be called the enhancement factor, and it is shown in column 7 of Table 1 Fig 3 shows the enhancement factor for increasing irradiation obtained from the pooled results of eight experiments There is a good deal of variation between experiments, but it appears from the figures that the increase in transformation frequency is related to dose of X-rays at least up to 500 r At higher doses the number of surviving cells is too few for satisfactory estimates

From these results it may be concluded that prior irradiation of *BHK*21 cells followed by polyoma virus

Table 1 INCREASE IN FREQUENCY OF TRANSFORMED COLONIES ARISING FROM *BHK*21 CELLS EXPOSED TO POLYOMA VIRUS AFTER X-IRRADIATION OF THE CELLS

Dose of X-ray (r)	Normal colonies / Cells plated	(%)	Transformed colonies / Cells plated	(%)	Transformed colonies / Total colonies (*M*) (%)	Enhancement factor*
0	548/1,200	46	30/1,200	2 5	5 2	—
188	812/3,200	25	71/3,200	2 2	8 0	1 5
375	509/9,000	5 6	115/12,000	0 97	12 8	2 5
500	545/12,000	4 4	94/12,000	0 78	14 8	2 8

* Enhancement factor is ratio of transformed colony frequency (column 6) with irradiated cells compared with unirradiated cells

Table 2. INCREASE IN FREQUENCY OF TRANSFORMED COLONIES ARISING FROM IRRADIATED CELLS INFECTED IN MONOLAYERS TO AVOID CELL AGGREGATION

Dose of X-rays (r)	Unclumped cells (%)	Normal colonies / Cells plated	(%)	Transformed colonies / Cells plated	(%)	Transformed colonies / Total colonies (%)	Enhancement factor*

* See Table 1

infection increases the probability that the survivors will yield transformed clones.

Possible effect of cell aggregation. Both unirradiated and irradiated *BHK*21 cells in suspension are markedly aggregated by polyoma virus. For example, the cell suspension used for the assay shown in Table 1 contained about half the cells in clumps of two or more. Earlier experiments have shown that clumping does not affect the number or growth of transformed colonies, by comparison with colonies arising from single cells[4,9]. This is probably due to dispersal of the clumps after dilution of the infected suspension. It was still important to show that cell aggregation had no effect on the enhancement of the transformation after irradiation. For example, it was possible that a transformed cell in an aggregate with an untransformed cell might be more likely to form a transformed colony if the normal cell were previously damaged by irradiation.

Attempts to obtain single cell suspensions by sedimentation of aggregates after infection in suspension were unsuccessful. It was therefore decided to adsorb the virus to cells immobilized in monolayer cultures, and then to suspend the cells and assay for transformed colonies in the usual way. Preliminary experiments showed that cells suspended from monolayers immediately after adsorption of virus were still aggregated, perhaps because virus was still attached to the cell surface. However, if after adsorption the infected monolayers were left intact under medium for 3 h before suspension, it was possible to obtain predominantly single cell suspensions.

In terms of virus dose, transformation occurred less frequently when cells were infected as monolayers. In the technique finally adopted $1 \cdot 3 \times 10^9$ plaque-forming units in 0.2 ml of buffer were allowed to adsorb for 1 h at 37°, but this produced a lower transformation frequency than the standard exposure of cells in suspension to 10^9 plaque-forming units in 1 ml.

To determine the effect of irradiation on transformation using well-dispersed cells, separate monolayer cultures were exposed to increasing doses of X-irradiation, washed with buffer, and infected as described. The cells were then incubated in 5 ml of *ETC* medium for 3 h at 37°, suspended, and counted. The proportion of single cells ranged from 90 to 99 per cent and only two clumps with more than 2 cells were found. Table 2 gives the results of the assay. It will be seen that the increased transformation frequency was still observed with irradiated cells, even though the majority of cells were not aggregated.

*Effect of irradiated uninfected BHK*21 *cells on colony formation by transformed cells.* The increase in relative numbers of transformed colonies arising from irradiated cells did not necessarily mean that there was a real increase in the proportion of cells transformed. There might simply be a greater chance that transformed cells would form colonies when plated under these conditions after prior irradiation. Despite the presence of a large excess of irradiated mouse feeder cells in all assay plates, it was possible that addition of irradiated *BHK*21 cells might in some way enhance the growth of transformed cells.

To investigate this possibility, a standard transformation assay was carried out with 10^6 unirradiated *BHK*21 cells exposed to 10^9 plaque-forming units per ml of polyoma virus. 10^3 infected cells were then plated on irradiated mouse feeder layers, with and without the addition of five times the number of uninfected *BHK*21 cells irradiated with 750 r. Table 3 shows the results. About 5 per cent of the added irradiated cells survived, and this contributed to the increased total colonies counted in the assay with irradiated cells. It is clear that the presence of homologous irradiated cells did not alter the growth and colony formation by freshly transformed cells.

Table 3. EFFECT OF EXCESS IRRADIATED HAMSTER CELLS ON STANDARD POLYOMA TRANSFORMATION ASSAY USING UNIRRADIATED CELLS

No. of uninfected hamster cells irradiated (750 r.)	No. of infected hamster cells unirradiated	No. of colonies Total	No. of colonies Transformed	Transformed colonies / Total colonies (%)
Nil	1,000	407	24	5.9
5,000	1,000	458	22	4.8
10,000	nil	224	0	—

Conclusions. It will be seen from these results that the apparent frequency of transformation by polyoma virus is increased among cells which have survived X-irradiation. This effect might be due to an increase in the colony-forming efficiency of transformed cells rather than to an increase in the number of initial transformations. There was no evidence, however, that the experimental conditions following irradiation favoured the growth of transformed cells in the assay system, nor was the effect influenced by cell aggregation. It therefore seems likely that relatively more cells were actually transformed among the survivors after irradiation.

There is no direct evidence of polyoma virus multiplication in *BHK*21 cells, and even if new virus was produced by irradiated cells, the additional contribution would be unlikely to affect the transformation frequency by fresh infections. A satisfactory explanation of the phenomenon is yet to be found, but there are two main possibilities.

First, the population may be heterogeneous, and contain cells which are selected because they are genetically, or for temporary physiological reasons, more resistant to irradiation. These resistant cells may for some unknown reason also be more sensitive to polyoma transformation.

Secondly, it may be supposed that damage by X-irradiation directly causes an increase in sensitivity to the virus transformation. Such damage would have to be sub-lethal for the transformation to become manifest, unless one supposes that the virus can rescue otherwise lethally irradiated cells.

Whatever the explanation, if X-irradiation increases the susceptibility of cell populations to transformation by polyoma virus, it may also increase the sensitivity to other tumour viruses. If so, one factor in the carcinogenic effect of X-irradiation may be the increased probability that virus-induced tumours will arise in irradiated tissue. It will be desirable to test the effect of other carcinogens on cell susceptibility to tumour viruses.

ADENOSINE TRIPHOSPHATE-DEPENDENT REDUCTION OF NICOTINAMIDE ADENINE DINUCLEOTIDE BY FERRO-CYTOCHROME *C* IN CHEMOAUTOTROPHIC BACTERIA

By Dr M. I. H. ALEEM and Dr H. LEES

RECENT biochemical investigations with chemoautotrophic bacteria have been concerned with the mechanism of electron transfer[1-4], phosphorylation systems coupled to the oxidation of inorganic compounds[5-8] and with the fixation of carbon dioxide[9,10]. One of the metabolic problems remaining to be resolved is the source of reducing power required to drive the endergonic processes associated with the fixation of carbon dioxide. Since chemoautotrophic bacteria do not utilize sugars or organic acids as primary energy sources and do not use light energy as do photosynthetic organisms, there has been much speculation about the source of reducing power and how it is generated in these organisms. It is well known that reduced nicotinamide adenine nucleotides are required for fixation of carbon dioxide in photosynthesis, and recently adenosine triphosphate (ATP) and reduced nicotinamide adenine dinucleotide (NADH) were found to stimulate the incorporation of carbon dioxide into cell-free extracts of the nitrifying bacterium *Nitrobacter*[9]. Since the potentials of the compounds oxidized by chemoautotrophic bacteria are much more positive than the NAD/NADH couple, NO_2^-/NO_3^-, +0·421, $NH_4OH/NH_2OH.H$, +0·562, NH_2OH^+/NO_2^- +0·45; Fe^{2+}/Fe^{3+}, +0·77, NAD/NADH, −0·32; a mechanism which involves the reversal of electron transfer may be involved in reducing the nicotinamide adenine nucleotides although Gibbs and Schiff[11], in a recent review, do not favour this possibility. In this communication we show that NAD is reduced by ferro-cytochrome *c* in cell-free extracts of *Nitrobacter*, *Nitrosomonas* and *Ferrobacillus* provided ATP is added. The concept of an energy-dependent electron flow from succinate to NAD promoted by ATP or energy-rich precursors of ATP in animal mitochondria was first proposed by Chance and Hollunger[12]. Chance and Olson and Chance and Nishimura[13] suggested that a similar process would account for the light-stimulated NAD reduction in intact cells of purple bacteria. Bose and Gest[14] showed that the 'photoreduction' of NAD or fumarate by succinate and photo-evolution of hydrogen in *Rhodospirillum rubrum* was promoted by 'dark' oxidation-reduction reactions which were dependent on energy-rich intermediates produced by the interaction of light with the photo-chemical apparatus.

Cells of *Nitrosomonas europaea*, *Nitrobacter agilis* and *Ferrobacillus ferrooxidans* grown in batch cultures were collected in a Servall continuous flow centrifuge. Cells of *Nitrosomonas* or *Nitrobacter* were washed in 0·05 M

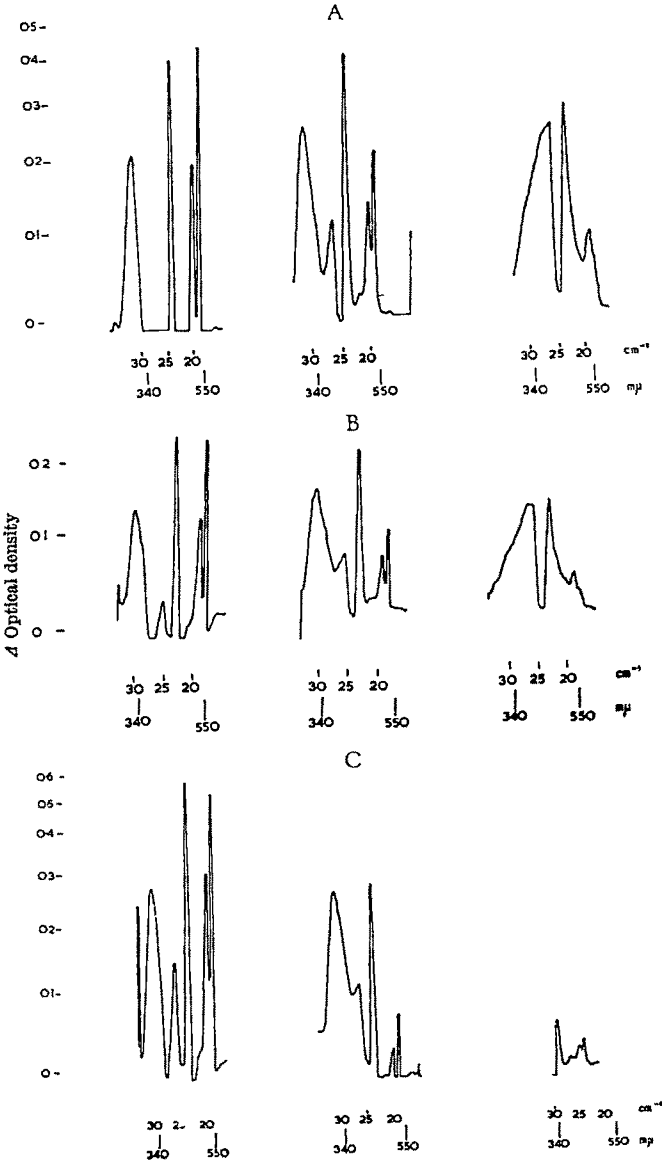

Fig. 1. Effect of adenosine triphosphate on the reduction of nicotinamide adenine dinucleotide by mammalian ferro-cytochrome *c* by cell-free extracts of *Nitrobacter* (fraction *a*). The results illustrate rapid scans, each taking 30 sec, of a difference spectrum over the range 30–25 cm⁻¹ or 300–600 mμ made in a Unicam *SP* 700 recording spectrophotometer. The reaction was followed under anaerobic conditions in special silica cuvettes (1 cm light path) fitted with Thunberg attachments. The reaction mixture contained 2 μmoles NAD, 0·05–0·1 ml. enzyme (preparation *a* or *b*) containing 0·5 mg protein/ml., in a final volume of 3 ml. 0·1 M *tris*–hydrochloric acid buffer *p*H 7·8. Adenosine triphosphate (40 μmoles in 0·2 ml. of the buffer) was added to the test cuvette only. Mammalian cytochrome *c* (horse heart, Sigma type III) was reduced with palladized asbestos and hydrogen, and 0·3 μmoles in 0·2 ml. *tris*–hydrochloric acid buffer was put in the sidearm of the Thunberg cuvette. After evacuating and gassing the cuvette with oxygen-free nitrogen (repeated three times), the reduced cytochrome *c* was tipped into the cuvette to start the reaction, which was then followed over a period of 10 min by the rapid scanning technique. The following enzymatic traps for NADH were also included in some of the reaction mixtures: alcohol dehydrogenase (0·1 mg crystalline preparation from yeast) and 0·1 ml. 1 per cent acetaldehyde (Fig. 1*B*) and lactic dehydrogenase (50 μg crystalline Sigma type I from rabbit muscle) and 5 μmoles sodium pyruvate (Fig. 1*C*). Time differences between the scans (left to right) are 1 and 2 min.

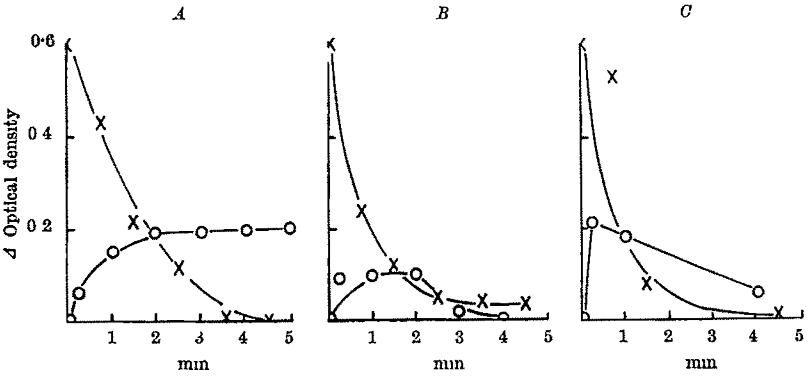

Fig. 2. Reduction of nicotinamide adenine dinucleotide (NAD at 340 mμ, O—O) by mammalian ferro cytochrome *c* (550 mμ, ×—×) in the presence of adenosine triphosphate (ATP) in cell-free extracts of *Nitrobacter* (fraction *a*). The results plotted from rapid scans, each taking 30 sec of a difference spectrum over the range 300–600 mμ in a Unicam *SP* 700 recording spectrophotometer. Details of reaction mixtures given in Fig. 1. Reaction mixtures in Fig. 2*A* as for Fig. 1*A*; in Fig. 2*B* as for Fig. 1*B* (containing the alcohol dehydrogenase trap), in Fig. 2*C* as for Fig. 1*C* (containing the lactic dehydrogenase trap)

tris-hydrochloric acid buffer (*p*H 7·5) and *Ferrobacillus* in de-ionized water adjusted to *p*H 2·5 with dilute sulphuric acid. Cell-free extracts were prepared by disrupting cells with a Mullard ultrasonic probe (20 kc/s) for 20 min at 0° and centrifuging at 10,000*g* for 30 min to remove cell debris. The supernatant fraction (*a*) was re-centrifuged at 144,000*g* for 1 h, resulting in a particle-free supernatant solution (*b*). Both fractions *a* and *b* were used as enzyme source.

The reduction of NAD (340 mμ) and the oxidation of reduced cytochrome (550 mμ) were followed by making a series of rapid scans, each taking about 30 sec, of a difference spectrum over the range 300–600 mμ using a Unicam *SP* 700 recording spectrophotometer. The reaction mixtures in 3 ml of 0·05 M *tris*-hydrochloric acid buffer (*p*H 7·8) contained 2 μmoles NAD, 0·1 ml 4 per cent mammalian cytochrome *c* (horse heart Sigma type III) reduced with palladized asbestos and hydrogen, in an apparatus designed by Walker and Nicholas[15], and 0·05–0·1 ml enzyme containing 0·5 mg protein/ml. Adenosine triphosphate (40 μmoles) was included in the test cuvette only. The reaction was started by adding reduced cytochrome *c* to both cells. The experiments were performed under anaerobic and aerobic conditions. Since the addition of natural substrates to the assay mixtures, for example, nitrite for *Nitrobacter*, hydroxylamine for *Nitrosomonas* and ferrous iron for *Ferrobacillus*, would result in the reduction of the cytochrome components by the respective cytochrome *c* reductases, measurement of any ATP dependent oxidation of ferro-cytochrome *c* would not be feasible. Moreover, these substrates also have an appreciable absorption in the 340 mμ region.

Since oxidized cytochrome *c* has a shoulder near 340 mμ which could be confused with the NADH peak, it was essential to obtain unequivocal evidence for NADH formation by other methods. This was achieved by using two independent trapping systems involving the enzymatic action of alcohol dehydrogenase and acetaldehyde and that of lactic dehydrogenase and pyruvate, both of which specifically oxidize NADH.

In this communication we illustrate results for extracts of *Nitrobacter* only since they are similar to those obtained with *Nitrosomonas* and *Ferrobacillus*.

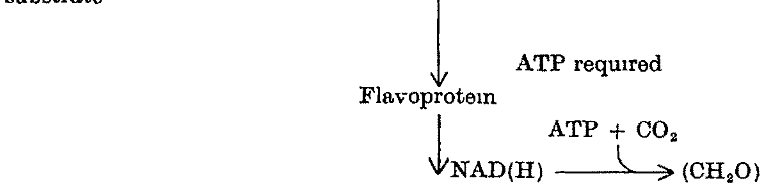
The results in Figs. 1 and 2 show that the reduction of NAD which is concomitant with the oxidation of ferro-cytochrome *c* is dependent on ATP. Within 1 min of starting the reaction there was a rapid formation of a compound absorbing at 340 mμ with a simultaneous oxidation of ferro-cytochrome *c* (Figs. 1*A* and 2*A*). That the compound absorbing at 340 mμ was NADH was confirmed by using the alcohol dehydrogenase (ADH) and the lactic dehydrogenase (LDH) traps (Figs. 1*B* and 2*B*, and 1*C* and 2*C*). The faster initial rate of production of NADH (maximum within 15 sec) and its subsequent rapid disappearance in the presence of the LDH trap is probably due to the differential behaviour of the ADH and the LDH traps. Whereas without a trap NADH formed and cytochrome *c* oxidized reached a steady state after 2 min, both were fully oxidized in the presence of the ADH or LDH systems. Inorganic phosphate was liberated from ATP during these reactions. NADP was a poor substitute for NAD in this system.

In the absence of either ATP or reduced cytochrome *c* no reduction of NAD could be demonstrated. Although in whole cells the theoretical ATP requirement for the reduction of NAD approximates to 4 : 1, in the cell-free systems, however, it is between 10 and 20 : 1. There was little enzymatic reduction of NAD when less than 5 μmoles ATP was used. The reduction of NAD by ferro-cytochrome *c* may involve flavin systems since atebrin (10^{-4} M) inhibited NADH formation and the addition of equimolar amounts of flavin mononucleotide (FMN) completely reversed this effect. Further evidence that flavins are involved in the electron flow was deduced from pronounced negative spectral changes in the region 375–385 mμ. Similar results were obtained with aged particles where presumably the link between flavin and NAD had been lost on storage or with fresh preparations using small amounts of ATP (< 10 μmoles).

It is concluded that the observed effects cannot be due to the differential behaviour of cytochrome oxidase in the two cuvettes since similar results were obtained under aerobic or anaerobic conditions. These effects were also observed in fraction *b* containing little of the oxidase, and it was established that ATP even at 40 μmoles did not depress cytochrome oxidase activity.

It has also been possible to demonstrate conclusively that the primary oxidation of an inorganic substrate catalysed by a chemoautotroph generates both the energy and the reducing power. Cell-free extracts from *Nitrobacter*, for example, when provided with nitrite, ADP and NAD, exhibited a marked and rapid stimulation in fixation of carbon dioxide. The carbon dioxide fixation rate dropped considerably on omission of any of the components, indicating thereby the dependence of the chemosynthetic carbon dioxide assimilating system on phosphorylation and the reduction of the pyridine nucleotide.

The following general scheme is proposed for the overall metabolism of chemoautotrophic bacteria, for example, *Nitrobacter*, *Nitrosomonas* and *Ferrobacillus*.



The reducing power required for the endergonic reduction of carbon dioxide in these organisms is generated by the reversal of electron transfer by ATP from ferro-cytochrome *c* to NAD. The unique ability of these bacteria to utilize ATP to reverse electron flow from electropositive to electronegative respiratory carriers is a physiologically important mechanism which is vital to their chemosynthetic mode of life

Experiments now in progress may elucidate whether the reduction of NAD results from a true reversal of electron transfer by the normal respiratory chain or whether other carriers are involved

One of us (M I H A) thanks the British Council for a visitors award and the National Research Council of Canada for the award of a travel grant which made it possible for him to undertake a part of this work at Long Ashton. We thank M A Wright, Chemical Microbiology Department, Long Ashton Research Station, for assistance with the growing and handling of batch cultures of the bacteria, and J A Pickard, Long Ashton, for help with the recording spectrophotometer.

IN VIVO DESTRUCTION OF EXOGENOUSLY APPLIED INDOLYL-3-ACETIC ACID AS INFLUENCED BY NATURALLY OCCURRING PHENOLIC ACIDS

By Dr. M. H. ZENK and G. MÜLLER

Botanical Institute, University of Munich

THERE is quite a controversy in the literature as to the growth activity of certain naturally occurring phenolic acids While Vendrig and Buffel[1,2] have stated that caffeic acid may be a very important growth substance, there is another possibility, that the phenols may act *in vivo* as inhibitors or activators of the indolyl-3-acetic acid (IAA) oxidizing system[3,4], thus influencing growth This influence of phenols was clearly established by enzymatic tests *in vitro* The significance of the influence of caffeic acid and other phenolic acids *in vivo* is, however, not yet clearly established[2]

Since the *in vivo* action of the IAA-oxidizing system has been questioned, with regard to its being an artefact produced by cut-surfaces[5], we tried first to demonstrate the *in vivo* existence of this enzyme system Carboxyl labelled IAA (IAA*) (synthesized via a modified procedure of Thesing and Schulde[6] by lowering the concentration of ^{14}NaCN gramine derivative = 1 · 1 5 spec act 3 4 μc /μmole) was used as a substrate As a result of the action of the IAA-oxidase on the auxin, IAA is decarboxylated[7] and the resulting $^{14}CO_2$ is flushed, together with the respiratory carbon dioxide, out of the reaction vessel by means of carbon dioxide free air and then trapped in potassium hydroxide using a Vigreux-column Refixation of the carbon dioxide by the tissue did not occur Thus, kinetic measurements of the IAA-oxidase were possible Dark-grown *Avena* coleoptiles were used as plant material In order to obtain undamaged tissue, the coleoptiles were cut 2 mm below the node in the mesocotyl part of the seedling The cut surface was closed by dipping the remaining mesocotyl part into liquid collodium After drying, the collodium formed a film on the tissue which was impermeable to any aqueous solution

Fig 1 shows that if the tissue is placed in an IAA solution, decarboxylation occurs readily The increase in the rate of decarboxylation is linear after a lag-period of 3 h. Since there was no cut surface, the coleoptiles had to absorb the IAA by cuticular absorption Part of the IAA entering the tissue was destroyed by a naturally occurring IAA-oxidizing system The destruction of IAA is independent of a wound-effect

Thus having demonstrated the *in vivo* existence of an IAA oxidase system, we determined the influence of certain phenolic acids on this system If the interpretation of the auxin-sparing action of some of the cinnamic acids is correct, then we would expect after the addition of the synergistic phenolic acids[8] an inhibition of the decarboxylation reaction On the other hand, growth antagonists should result in an enhancement of the IAA oxidation

In order to obtain more consistent and comparable results, the apical 3 mm of the coleoptiles were discarded and three successive 3 3-mm sections were prepared without the primary leaf 1 g ± 2 mg of those segments were used for an experiment The tissue was shaken gently at constant temperature (21° C), and carbon dioxide was collected at 2-h intervals for 12 h Fig 2 shows the

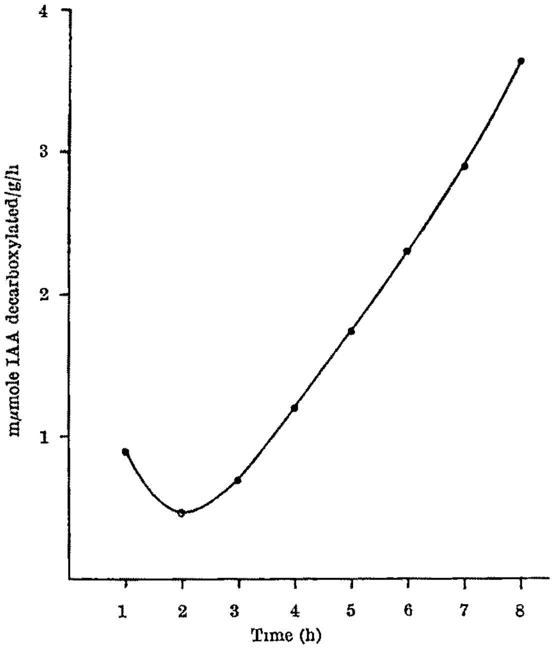

Fig 1 Kinetics of the decarboxylation of IAA* by intact *Avena* coleoptiles (var Victory), 2 cm long, with their cut ends in the mesocotyl part closed by the collodium film Incubation medium 12 5 ml 10^{-5} M IAA* (125 mμM) 10^{-3} M citrate phosphate buffer *p*H 5 0/g of coleoptiles Carbon dioxide was collected at hourly intervals and the radioactivity measured after correction for self-absorption and computed with the specific activity of the IAA used

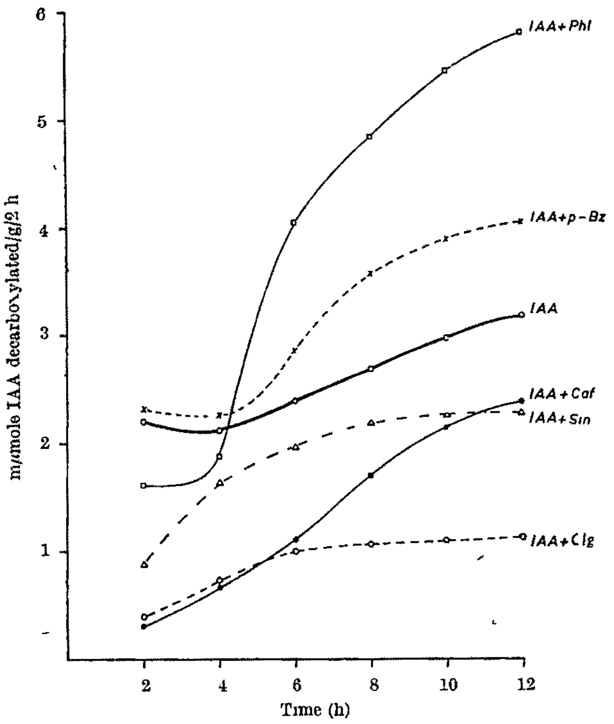

Fig 2 Kinetics of the decarboxylation of IAA* by 3-mm *Avena* coleoptile sections *in vivo* as influenced by phenolic acids Incubation medium 12·5 ml 10^{-5} M IAA (125 mμM), 10^{-3} M citrate phosphate buffer *p*H 5·0/g ± 2 mg coleoptile tissue and as indicated 10^{-4} M phenolic acids chlorogenic (Clg), sinapic (Sin), caffeic (Caf), *p*-hydroxybenzoic (*p*-Bz) and phloretic (Phl) acid The $^{14}CO_2$ was collected in 2-h intervals

influence of certain phenolic acids on the decarboxylation reaction. While the auxin synergists[6], caffeic, sinapic and chlorogenic acids actually inhibited the decarboxylation and therefore inhibited the inactivation of IAA, a slight enhancement of the *in vivo* destruction of IAA by the addition of *p*-hydroxybenzoic and phloretic acids was noticed

There are also reports of *p*-coumaric acid being a very effective cofactor of the IAA-oxidase *in vitro*[9], although *m*-coumaric and *o*-coumaric acid showed only negligible influence A drastic inhibiting influence of *p*-coumaric acid on IAA-induced growth could also be shown[4,8] Fig 3 demonstrates the influence of the isomeric coumaric acids on the decarboxylation of IAA by *Avena* coleoptile sections While *m*- and *o*-coumaric acid are only slightly active in promoting the decarboxylation, *p*-coumaric acid has an extremely stimulating effect on this reaction There is, starting with the fifth hour, a linear increase in the rate of decarboxylation of IAA The total amount of IAA decarboxylated per 2-h intervals increases logarithmically over the measured period of 12 h With IAA alone in the incubation fluid no such drastic increase of the rate of IAA destruction is observed *p*-Coumaric acid is known to stimulate *in vitro* the oxidation of IAA very markedly, we, however, do not feel that the action of *p*-coumaric acid is a matter of adapting the enzyme system which is responsible for IAA destruction *in vivo*[10] Thus, after the addition of Mn^{++} ions in a final concentration of 10^{-3} M to the incubation medium containing IAA and the coleoptile sections, the decarboxylation rate of IAA increases immediately 300 per cent over the IAA control without showing a lag period This suggests that the enzymes for IAA decarboxylation are already present, but not functioning at such a high turnover rate The increase in the decarboxylation rate induced by *p*-coumaric acid is as yet not clear

The influence of the concentration of *p*-coumaric acid on the decarboxylation during an 8-h period is shown in Fig 4 There is a maximum increase in the auxin destruction rate at 10^{-4} M Similar to the *in vitro* experiments, 0·1 μM *p*-coumaric acid/ml seems to be optimal also for auxin destruction *in vivo*

Finally, the influence of different phenolic acids on the uptake and decarboxylation of IAA during a 12-h period was investigated *in vivo* and compared with the effect

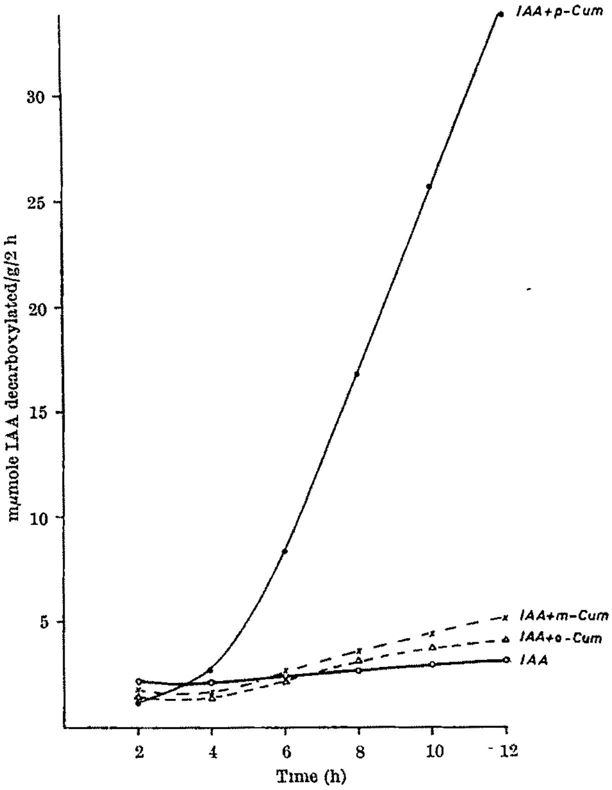

Fig 3 Kinetics of the decarboxylation of IAA* by 3-mm *Avena* coleoptile sections *in vivo* as influenced by 10^{-4} M coumaric acids Incubation medium as in Fig 2 *p*-Coumaric (*p*-Cum), *m*-coumaric (*m*-Cum) *o*-coumaric (*o*-Cum) acid

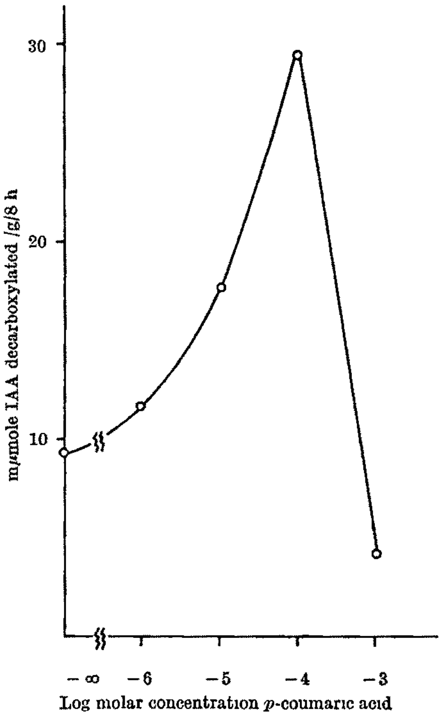

Fig 4. Decarboxylation of IAA* by 3-mm *Avena* coleoptile sections *in vivo* in the presence of various molar concentrations of *p*-coumaric acid Incubation medium 12·5 ml 10^{-5} M IAA (125 mμM), 10^{-3} M citrate phosphate buffer *p*H 5·0/g of coleoptile tissue and the indicated amount of *p*-coumaric acid

Table 1

IAA 10^{-5} M + various phenolic acids 10^{-4} M	Uptake mμmoles IAA/g/12 h	IAA control (%)	Decarbox mμmoles IAA/g/12 h	IAA control (%)	Enzymatic destruction of IAA in control (%)
IAA control	46.0	100	14.9	100	100
+ Chlorogenic acid	52.0	113	5.4	36	73
+ Caffeic acid	46.0	100	7.9	53	79
+ Dihydrocaffeic acid	41.5	90	10.4	69	88
+ Sinapic acid	46.2	100	11.2	75	83
+ *p*-Coumaric acid	32.0	69	90.6	608	181
+ *o*-Coumaric acid	39.6	87	16.4	109	104
+ *m*-Coumaric acid	45.3	98	19.5	131	117
+ Phloretic acid	36.8	80	23.2	155	188
+ *p*-OH Benzoic acid	37.0	80	18.9	127	113
+ Ferulic acid	45.6	99	21.0	141	126
+ Isoferulic acid	36.7	80	20.4	137	101
+ Cinnamic acid	39.9	86	14.1	94	100
+ Tyrosine	40.2	87	14.1	94	100

of the same acids on the IAA oxidase from peas[11]. The amount of IAA taken up by the tissue was measured after the end of the 12-h incubation by extracting the coleoptiles with hot ethanol and determining the radioactivity in an aliquot of the alcoholic solution[12].

According to Table 1 the tested phenols can be divided into three groups. The synergistic acids (chlorogenic, caffeic, dihydro-caffeic, and sinapic) which inhibited the decarboxylation of IAA, thus clearly having an auxin-sparing influence. Secondly, the growth-inhibiting phenols (*p*-coumaric, phloretic, ferulic, isoferulic, *m*-coumaric, *p*-hydroxybenzoic, *o*-coumaric acids). Those acids increase the IAA decarboxylation, depriving the tissue of auxin, and thus retarding growth. Thirdly, acids which influence neither growth nor decarboxylation (cinnamic acid and tyrosine). Gibberellic acid is in contrast to *in vitro* experiments[13] without any influence on IAA decarboxylation *in vivo*. The auxin-sparing action of the synergistic phenols is also reflected in the higher amount of IAA taken up by the coleoptiles. Tissue in the presence of *p*-coumaric acid, on the other hand, shows the least uptake of IAA.

The influence of the various phenolic acids on the *in vivo* decarboxylation is closely resembled by the *in vitro* destruction of IAA by an enzyme system from peas. There is, however, an interesting exception. We are able to confirm the report[9] that phloretic acid enhances the enzymatic oxidation of IAA drastically *in vitro*; however, there was only a slight effect on the *in vivo* system compared with *p*-coumaric acid. In the case of caffeic acid, the dihydro form is about 20 per cent less effective in inhibiting the decarboxylation of IAA than caffeic acid itself. We have observed that the phenolic acids taken up by the coleoptiles are converted in the corresponding glucose esters, which occur widely in Nature[14,15]. Those esters are still effective as modifiers of the IAA oxidase. It could be possible that the dihydrocinnamic acids are partly metabolized in a different way, thus showing less influence on the oxidation of IAA *in vivo*, or reaching only a lower effective concentration in the tissue than the corresponding cinnamic acids. Generally, however, the same structural requirements for the cinnamic acids to influence growth[4,8] and the IAA oxidase *in vitro*[9] and *in vivo* hold true. We feel, therefore, that it is now clearly established by means of *in vivo* experiments that the phenolic synergists and phenolic inhibitors of growth act through inhibition or activation of the IAA-oxidizing system.

SOME EFFECTS OF ADRENALINE AND ANTI-ADRENALINE COMPOUNDS ON PLATELETS *IN VITRO* AND *IN VIVO*

By DR. J. R. O'BRIEN

Portsmouth and Isle of Wight Area Pathological Service, Central Laboratory, Portsmouth

It has often been suggested that 'stress' may release noradrenaline into the blood stream and that 'stress' may precipitate arterial thrombosis. Platelet-to-platelet adhesion, that is platelet aggregation, plays a part in thrombus formation and in hæmostasis of small blood vessels as, for example, in the Borchgrevink bleeding time[1]. In 1941 Derouaux[2] showed that in some circumstances the catecholamines may shorten the bleeding time, and recently Mitchell and Sharp[3,4] have shown that noradrenaline causes platelet aggregation *in vitro*, while Mustard[5] has shown that adrenaline shortens the half-life of platelets in the pig. These observations may be inter-related and suggested a detailed examination of the effect of the catecholamines on platelets.

Fresh citrated human platelet-rich plasma is placed in a magnetically stirred cuvette in a colorimeter at 37° C and the light transmission is continuously recorded. An increase in transmission occurs when the platelets aggregate and a decrease occurs if the platelet clumps come apart—disaggregation[6]. The addition of adrenaline acid tartrate to give a final concentration of M × 10^{-6} causes immediate partial aggregation followed by a lag phase when slight disaggregation may occur. This is followed by rapid and total aggregation. Inspection of a family of curves obtained when different doses of adrenaline were added (Fig. 1) shows that the slope of the initial aggregation is linearly related to the log of the dose. The time after the addition of adrenaline to the beginning of the lag phase, that is to the first inflexion in the curve, decreases slightly with higher concentrations. The length of the lag phase is also dependent on the dose, but the final aggregation is independent of the initiating concentration and is always rapid and complete. Exactly similar curves are obtained by adding noradrenaline, which is ten-fold less active. Isoprenaline is inactive.

Adenosine and adenosine monophosphate (AMP) have been shown to inhibit aggregation caused by adenosine diphosphate (ADP), thrombin, 5-hydroxytryptamine (5-HT) and they delay the effects of tri-ethyl tin[6,7]. These two inhibitory compounds at a final strength of

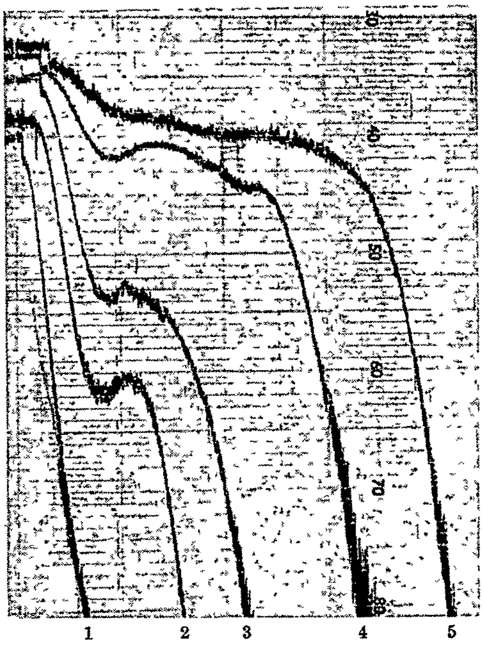

Fig 1 Light transmission is recorded on the ordinate, a decrease indicating aggregation The abscissa records time, one major division represents 2 min Adrenaline in 0 1 ml saline was added after the control (horizontal) period to give the following final concentrations curve 1, 5 M × 10^{-6}, curve 2, M × 10^{-6}, curve 3, 5 M × 10^{-7}, curve 4, 2 M × 10^{-7}, curve 5, M × 10^{-7}

5 M × 10^{-5} added before adrenaline 2 M × 10^{-6} inhibit aggregation added during the lag phase they will still inhibit the second phase of aggregation Adenosine triphosphate (ATP) inhibits ADP-induced aggregation but has no effect or enhances aggregation caused by thrombin or 5-HT or by tri-ethyl tin[7] ATP M × 10^{-6} added before a small dose of adrenaline or noradrenaline causes an increase in the degree of aggregation in the first phase but has little effect on the subsequent stages A much higher concentration of ATP added before the adrenaline may modify or block the second phase of aggregation

If phentolamine ('Rogitine'), which is an inhibitor of other pharmacological actions of adrenaline, is added in equimolar concentrations before the addition of adrenaline it completely inhibits aggregation and this inhibition is apparently competitive since a ten-fold increase in adrenaline requires a ten-fold increase in phentolamine to cause an equal degree of inhibition Another anti-adrenaline compound, dibenyline and the anti-serotonins '*Ro* 3/0837' and, '*UML* 491' have no effect on adrenaline-induced aggregation except at a relatively high concentration (10 µg/ml)

The interpretation of these findings is difficult particularly because we do not know the nature of the alteration in the platelet surface when it becomes more 'sticky' and because more than one kind of alteration may result in a similar degree of stickiness Adrenaline and noradrenaline initiate two waves of aggregation which can be separated and have other differences, yet both waves are inhibited by the same compounds All these findings are compatible with the hypothesis that adrenaline causes platelet ADP probably derived from ATP to be liberated and that this release is concerned with the 'stickiness'. Indeed, Spaet[8] has recently shown spectroscopically that nucleotides are in fact liberated It is remarkable that noradrenaline, 5-HT and the adenosine phosphates are all normally present in the platelets and the addition to the plasma of each of these substances causes aggregation, although these reactions when examined in detail show important differences On the other hand, thrombin and tri-ethyl tin which also cause aggregation are not present in the platelet Many problems of kinetics biochemistry and physical chemistry are raised but not answered by these observations

Table 1 COMPOUNDS INDUCING PLATELET AGGREGATION AND THEIR INHIBITORS

Aggregating compound	Concentration	Specific inhibitor
Adenosine diphosphate	M × 10^{-8}	Adenosine*
5-Hydroxytryptamine	5 M × 10^{-6}	'*UML* 491' ('Deseryl')
Adrenaline	M × 10^{-7}	Phentolamine ('Rogitine')
Noradrenaline	5 M × 10^{-7}	
Thrombin	0 06 U/ml	Heparin

* Adenosine inhibits aggregation produced by all these aggregating compounds

Any of the physiological substances shown *in vitro* to produce aggregation might be involved *in vivo* This problem could be investigated since each aggregating compound has *in vitro* a specific competitive inhibitory compound(s), which has virtually no effect on aggregation induced by other compounds (Table 1) Accordingly, these specific inhibitors and some other compounds dissolved in 0 1 ml of saline were injected intradermally into the human forearm and the Borchgrevink bleeding time was estimated from cuts made through the injected areas From Table 2 it will be seen that only phentolamine caused prolongation of the bleeding time Erythema and local œdema were produced by phentolamine and to an even greater extent by histamine and hyaluronidase, but neither of the last two injections prolonged the bleeding time Accordingly, the prolongation of the bleeding time by phentolamine suggests that it may specifically inhibit adrenaline or noradrenaline, and, therefore, that these catecholamines may normally be responsible for platelet adhesion or aggregation in these circumstances The other compounds studied did not prolong the bleeding time, nor does heparin unless it is present at a very high concentration[9] Thus these experiments also suggest that ADP (other than that liberated from adrenaline) and thrombin and 5-HT do not play a major part in capillary hæmostasis

Table 2 EFFECT OF INHIBITORS, ETC, ON THE BLEEDING TIME

Material injected	Amount injected	No of observations	Mean bleeding time (min)
Saline		8	3 5
Adenosine	0 25 mg	4	4 5
'*UML* 491'	0 1 mg	4	3 95
Phentolamine	0 5 mg	8	>12 5
Phentolamine	0 05 mg	4	5 5
Dibenyline	0 3 mg	2	4 2
Histamine	0 05 mg	12	3 75
Hyaluronidase	30 I U	2	2 7

Table 3 SOME EFFECTS OF CATECHOLAMINES AND THEIR INHIBITORS

	Smooth muscle stimulated	Platelet aggregation *in vitro*	Bleeding time prolongation
Adrenaline	Yes	Yes	—
Noradrenaline	Weaker	Weaker	—
Isoprenaline	No	No	—
Adrenaline effect inhibited by			
Phentolamine	Yes	Yes	Yes
Dibenyline	No	No*	No

* Except at a high concentration

The results presented have no direct bearing on thrombosis circumstantially and indirectly they suggest that the local release of adrenaline or noradrenaline may activate the hæmostatic mechanism perhaps by liberating ADP The remarkable parallelism of the effects of the catecholamines and their inhibitors in three very different situations, namely, the nictitating membrane of the cat *in vivo*, platelet aggregation *in vitro* and the bleeding time (Table 3) might suggest that some basic common process is involved

RADIOASTRONOMY

Faraday Rotation Effect in Extragalactic Radio Sources

Cooper and Price[1] have shown that the polarization of radio emission measured at three different points in the radio source Centaurus *A* rotated progressively with increasing wave-length They found the rate of rotation to be proportional to the square of the wave-length This fact suggested to Cooper and Price a direct explanation in terms of Faraday rotation in a magneto-ionic medium. Recently, Gardner and Whiteoak[2] measured the polarization of 18 radio sources at different wave-lengths in order to investigate whether Faraday rotation was present All the sources showed the quadratic dependence of polarization position-angle on wave-length characteristic of Faraday effect In the discussion of their results, Gardner and Whiteoak suggested the possibility that some of the Faraday rotation occurs in our Galaxy (Fig 1 in ref 2)

The Faraday rotation θ of the plane of polarization of radio radiation from an extragalactic source at a wave-length λ can be expressed as a sum of four different terms

$$\text{const}\,\frac{\theta}{\lambda^2}=\underbrace{\int N_{e1}H_1\mathrm{d}r}_{\text{ionosphere}}+\underbrace{\int N_{e2}H_2\mathrm{d}r}_{\text{galaxy}}+\underbrace{\int N_{e3}H_3\mathrm{d}r}_{\text{intergalactic space}}+\underbrace{\int N_{e4}H_4\mathrm{d}r}_{\text{radio source}} \quad (1)$$

each of which contributes to the integral effect observed The symbols N_{ek} and H_k stand for electron density and longitudinal magnetic field When θ is measured in radians, λ in metres, N_e in particles/c c , H in gauss and r in parsecs, the constant has the value 0 124 × 10^{-5} According to results obtained by Evans[3], the first integral is nearly two orders of magnitude smaller than the observed value of the left-hand term in equation (1), therefore the ionospheric contribution to the Faraday rotation effect in radio source radiation is negligible Also, the third term in equation (1) appears to be negligible, because although the path of radiation through intergalactic space is very long there is no evidence of sufficiently high magnetic fields and electron densities This point of view seems to be supported by the lack of correlation between the Faraday rotation measure and the distance of the radio sources, although such a correlation might not occur if the intergalactic magnetic fields were not sufficiently regular Hence the majority of the rotation probably occurs either within our own Galaxy or within the radio source itself

Gardner and Whiteoak[2] discussed the possibility of a galactic origin for the main part of the Faraday rotation Although they showed that sources with the smallest rotations are at high galactic latitudes, the considerable scatter in both magnitude and sign of the rotation at intermediate latitudes makes the galactic origin of the main part of Faraday rotation less probable

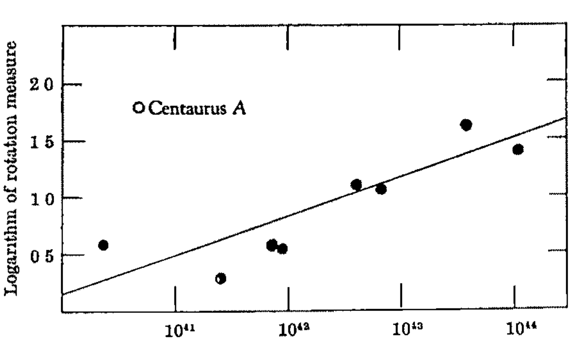

Fig 1 Total luminosity versus Faraday rotation measure for extragalactic radio sources

Let us examine in more detail the hypothesis that Faraday rotation is produced mainly within the source itself Under the condition of minimum total energy of a radio source radiating by means of an acceleration-radiation mechanism, the prevailing magnetic field is

$$H\propto\psi^{-2/7}L^{2/7}r^{-6/7} \quad (2)$$

where L is the total radio luminosity, ψ is a 'filling factor' determining the portion of the source's volume occupied by filaments and knots of the magnetic field and relativistic particles trapped in it, and r is the radius of the emitting region[4]

The Faraday rotation measure depends on r and H through the relation

$$\lambda^{-2}\theta\propto N_eHr \quad (3)$$

For the purpose of correlation testing, it is reasonable to assume that the magnetic field in expression (2) and the longitudinal magnetic field in expression (3) are comparable Therefore, on the basis of the order-of-magnitude relation

$$L\propto\psi H^{\frac{1}{2}}N_e^{-3}\,(\lambda^{-2}\theta)^3 \quad (4)$$

we can expect a correlation between radio luminosity L and rotation measure $\lambda^{-2}\theta$, if the rotation is produced mainly in a radio source itself

The correlation between total radio luminosity L and rotation measure $\lambda^{-2}\theta$ for extragalactic radio sources is shown in double logarithmic scale in Fig 1 The polarization data were given by Gardner and Whiteoak[2] and the values of total luminosities by Maltby, Matthews and Moffet[4] The points in Fig 1 represent those extragalactic radio sources from Gardner and Whiteoak's list for which the distance is known The full line represents the expected relation between total luminosity and rotation measure given by (4), provided the factor $\psi H^{\frac{1}{2}}N^{-3}$ does not change considerably The line has a slope equal to 0 33

The open circle in Fig 1 corresponds to the values of L and $\lambda^{-2}\theta$ for the central source of Centaurus *A* As is well known, the central source of Centaurus *A* is immersed in a large radiation halo of complex structure It is very probable that polarized radiation from the central source, passing through the extended halo region, will be subject to additional Faraday rotation, the amount of which may be very large because of the size of the extended source and the magnitude of possible magnetic fields (6 × 10^{-6} gauss (ref 4)) This could explain the deviation of the open circle in Fig 1

In so far as it is possible to draw conclusions on the basis of only eight points, the correlation expressed in Fig 1 strongly suggests that the Faraday effect occurs mainly within radio sources, not in the Galaxy or in intergalactic space Furthermore, the rather small scatter of points in Fig 1 indicates that the factor $\psi H^{\frac{1}{2}}N^{-3}$ does not vary greatly from one radio source to another

Occultation of the Crab Nebula by the Solar Corona in June 1963

In a recent communication, Basu and Castelli[1] described observations at wave-lengths of 10 cm and 25 cm of the occultation of the radio source in Taurus, the Crab Nebula, by the solar corona in June 1962. The results were interpreted as indicating a progressive increase in the angular diameter of the source with decreasing angular distance from the Sun, due to scattering by irregularities of electron density in a non-uniform corona.

Several observers have demonstrated that such an effect occurs at metre wave-lengths, for example, Hewish[2,3] and Vitkevitch[4] have shown that, over the range of wave-lengths 1·9–7·9 m, and for radial distances less than 12 solar radii, the results are in accord with a simple scattering theory in which the angular extent of the scattered distribution (defined as the brightness distribution produced when a point source is viewed through the corona) is proportional to the square of the wave-length. Assuming this dependence on wave-length to hold down to centimetre wave-lengths, and extrapolating from the metre observations of Hewish, values ~2″ at 10 cm and ~10″ at 25 cm are derived for the expected angular diameter (between e^{-1} points) of the Gaussian scattered distribution at distances ~5 solar radii from the Sun. From their observations Basu and Castelli inferred angular diameters of 20′ at 10 cm and 25′ at 25 cm, which therefore cannot be accounted for by the simple theory.

In view of this discrepancy, observations of the Crab Nebula were undertaken in June 1963 using the twin 90-ft. dishes of the California Institute of Technology's Owens Valley Radio Observatory. The two antennæ were used as an east–west interferometer of spacing 680λ operating at a frequency of 1,660 Mc/s (18 cm wave-length). Any increase in angular diameter of the source, observed with the interferometer, results in a decrease in the recorded source response which may be interpreted directly in terms of the angular extent of the scattered distribution. With the arrangement described here, the quiet Sun was largely resolved and gave a contribution to the total response which was only a fraction of the response due to the source itself. In the absence of an appreciable solar contribution it was possible to detect scattering angles as small as 0·7′. The source was observed daily at several different hour angles during the period June 11–19, conjunction occurring on June 14–15 (Fig. 1). In order to allow for the solar contribution, additional observations of the response were made each day with the antennæ directed towards the positions which the source took relative to the Sun on each of the occulting days. The contribution was at all times less than 15 per cent except on June 15 when the solar response was 25 per cent of that due to the source. As the angular separation of source and Sun decreased, the gain was decreased by measured amounts (always less than 0·4 db) to preserve the same detector levels in the presence of solar noise. The response of the source 3C 123 was observed each day and used to correct for small changes in receiver sensitivity.

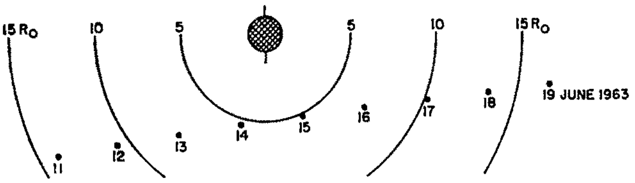

Fig. 1. Position of the Crab Nebula relative to the Sun at 12 noon P.S.T. $R_{\odot}$, Solar radius

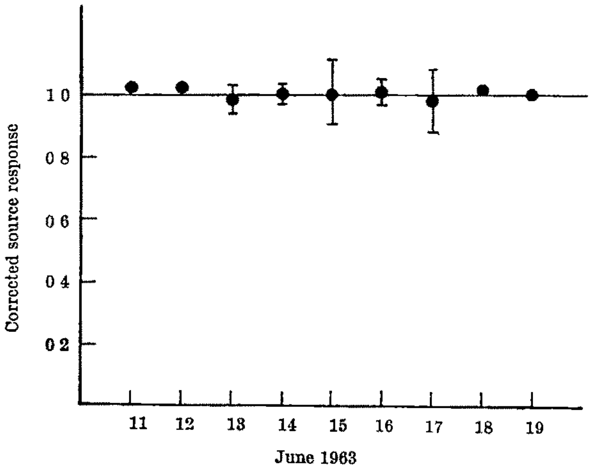

Fig. 2. Corrected response of the Crab Nebula. The error limits indicate uncertainties in removing the solar contribution. Results for hour angles ± 1 h have been combined in this figure

When the foregoing factors were taken into account in the analysis, no positive evidence for a variation in the source response, corresponding to an increase in angular diameter, was found (Fig. 2). The corrected source response remained constant to within 12 per cent, enabling an upper limit of 1·2′ to be set to the angular diameter of the scattered distribution in the east–west direction. The observations recorded here, therefore, give no evidence for the existence of enhanced scattering at centimetre wave-lengths which cannot be accounted for by the simple theory applicable at metre wave-lengths.

PHYSICS

Charge Transfer and Excimer Formation

The general properties of excited dimers, or excimers, have been well established[1-4]. In concentrated solutions of some polycyclic aromatic hydrocarbons, a singlet excited molecule can interact with an unexcited neighbour to produce the excited dimer, or excimer. This excimer can then break up into de-excited monomer molecules with the emission of a characteristic dimer fluorescence. The forces binding the dimer have been ascribed by Förster[5] to resonance dipole interaction. The criterion has been given for excimer formation that the molecule should possess a weak ^1L_b level lying beneath a strong ^1L_a level. Most of the excimer-forming molecules obey this criterion, a notable exception being anthanthrene.

It has been alternatively suggested[6] that the binding of the dimer may arise from charge transfer interaction in which one molecule donates charge to its partner or shares charge with its partner. In this picture the dimers behave like charge-transfer complexes and the excimer emission band is a charge-transfer band. It has been well established[7-9] that the frequency ν_{CT} of the charge transfer band is given to a first approximation by the relation:

$$h\nu_{CT} = I - E_A - \Delta \qquad (1)$$

when I is the ionization potential of the electron donor, E_A is the electron affinity of the electron acceptor and Δ represents the various other interaction terms, including resonance dipole interaction, which are assumed small. If the excimer emission is to be explained in terms of charge transfer one would expect a similar relationship between the frequency ν_D of the excimer emission, taken here as the frequency of strongest emission, and other molecular parameters, thus

$$h\nu_D = (I - S_1) - E_A - \Delta$$

The ionization potential of the excited molecule is $I - S_1$. S_1 is taken as ^1L_b.

In Table 1 are presented the ionization potentials, first singlet excited states (^1L_b) and electron affinities of 20 polycyclic aromatic hydrocarbons. Also presented in Table 1 are the energies of the excimer emission bands of those hydrocarbons forming dimers. The ionization potentials and electron affinities in Table 1 are those of the molecules in the vapour state. In solution they will be greatly reduced and increased respectively due to the polarization forces of the solvent. To a first approximation, the solvent can be assumed to have a similar effect on the energy-levels of all the molecules.

§ Aladekoma, J., and Birks, J. B. (to be published).

In Table 1 it is seen that those molecules which form dimers in solution at room temperature have $I - S_1$ less than 4.36 eV. All molecules having $I - S_1$ greater than 4.36 eV do not form dimers at room temperature. Anthracene, which forms a very stable dimer, has the very low $I - S_1$ value of 4.05 eV.

In Fig. 1 is shown a plot of $h\nu_D$ against $I - S_1 - E_A$. This is seen to give a good straight line with the exception of 3 4 benzpyrene, whose $I - S_1 - E_A$ value is 0.3 eV too low. Δ has been neglected and it is suggested that Δ does not vary greatly in this class of compounds. This correlation strongly suggests that the excimer emission band can be interpreted as a charge transfer band.

The meaning of the $I - S_1$ correlation is none too clear. The correlation would tend to suggest that possible charge transfer occurs as a two-stage process, the first stage involving ionization with perhaps the solvent acting as an intermediate.

Measurement of Ion Diffusion Coefficient in Liquid *n*-Hexane

By a method elaborated by me the diffusion coefficients of both negative and positive ions have been measured in liquid *n*-hexane at 25° C (ref. 1). This method is based on that of diffusion from a body of limited dimensions with boundary conditions. One-sign ions were introduced to the measuring chamber designed as a parallel plate condenser and then time decrease of ion number caused by diffusion was examined. Experimental conditions were chosen so that the influence of Coulomb repulsion of one-sign ions could be neglected.

The diffusion x coefficient was evaluated from the formula

$$D = \frac{(\ln Q_1 - \ln Q_2)\, l^2}{\pi^2 (t_2 - t_1)} \qquad (1)$$

where Q_1, Q_2 = electric charge measured for two measuring times t_1 and t_2, l = electrode distance.

Figs. 1 and 2 show the dependence $\ln Q = f\,t$ for both positive and negative ions in *n*-hexane. The coefficients of diffusion calculated from this dependence were $D_- = (2.75 \pm 0.22) \times 10^{-5}$ cm²/sec., $D_+ = (1.43 \pm 0.11) \times 10^{-5}$ cm²/sec. Hitherto there was no experimental method of direct measurement of diffusion coefficient of ions of one sign in dielectric liquids. The diffusion coefficient was calculated from Nernst–Einstein formula

$$\frac{u}{D} = \frac{e}{kT} \qquad (2)$$

where u = ion mobility, D = ion diffusion coefficient; k = Boltzmann constant; T = absolute temperature.

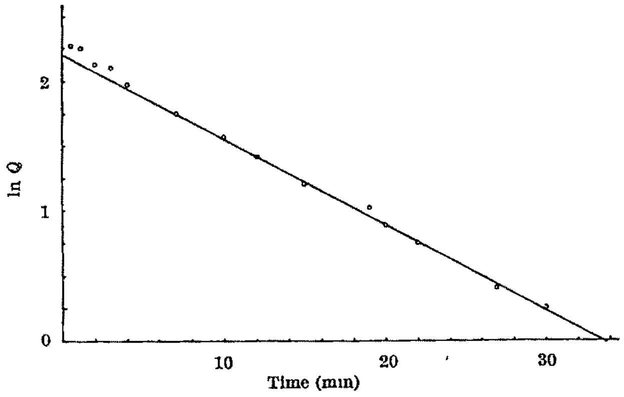

Fig. 1. Time decrease of the positive ions No. Electrode distance l = 3.6 mm

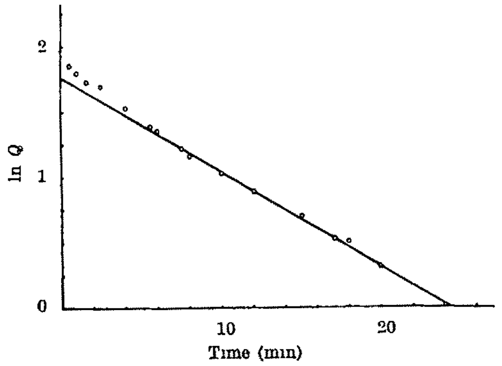

Fig 2. Time decrease of the negative ions No Electrode distance $l = 4\ 8$ mm

At 25° C the ratio $e/kT = 39$ V^{-1} and for results obtained by me $u_-/D_- = 34\ 5$ V^{-1}, $u_+/D_+ = 42\ 5$ V^{-1}

This ratio was calculated by the use of ion mobility values obtained by O Gzowski[2] I have also carried out the measurements of ion mobility using the method described in ref 3, and obtained the same values as in work in ref 2 Thus, within experimental error, the law of Nernst–Einstein is well confirmed for both positive and negative ions in *n*-hexane That conclusion is important, because it shows the difference between the thermal motion of molecules having uncompensated electric charge and the motion of neutral molecules

The measurements of self-diffusion coefficient carried out with different methods give[4] for it $D_0 = 4\ 2 \times 10^{-5}$ cm^2/sec In the work of Davis, Rice *et al* [5,6] the problem of such difference is discussed The ratio of self-diffusion to diffusion coefficient of positive ions evaluated by these authors was 3 – 5 for different liquids Ar$^+_2$, Kr$^+_2$, Xe$^+_2$

I thank Prof I Adamczewski for advice

Faraday Effect Ellipsometer

T P Murray[1] described the measurement by ellipsometry of the thickness of oil films present on commercial tinplate In his arrangement the elliptically polarized light reflected from the specimen surface was brought into a plane by means of a quarter-wave plate and the extinction position of the analyser found After de-oiling the specimen a new extinction position was found by adjustment of the analyser only, the difference being proportional to oil film thickness Angular shifts of a few tenths of a degree are common whereas the light intensity varies only slowly for several degrees about the minimum Murray overcame this difficulty by reading the analyser for equal photoelectric responses either side of the minimum, but it occurred to me that a more elegant technique, leading to an easier to construct and possibly more accurate instrument, would be to use Faraday cells as described by E J Gillham[2] for an automatic polarimeter

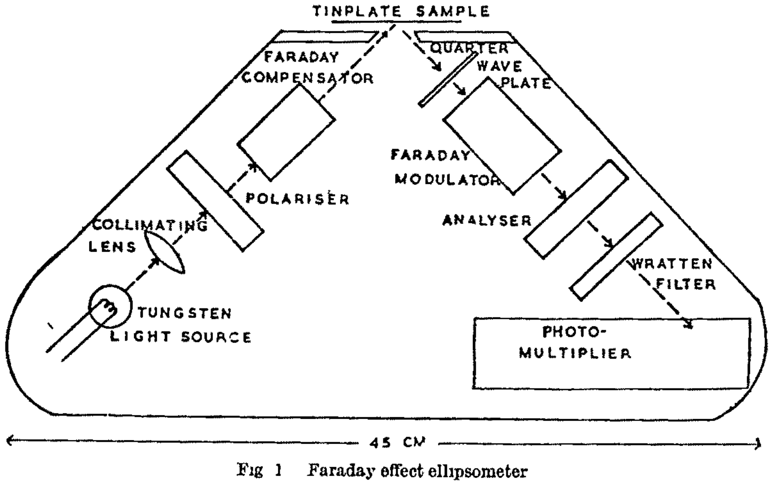

Fig 1 Faraday effect ellipsometer

Accordingly, a Faraday effect ellipsometer has been built primarily for measurements of thickness of oil on commercial tinplate but applicable to any metal substrate of reasonable brightness and flatness and bearing a removable transparent film of the order of a few molecules thick A diagram of the instrument is shown in Fig 1 The function of the Faraday cells is essentially the same as described by Gillham, one serving to oscillate the plane of polarization and thus modulate the light intensity while the other introduces a compensating shift equivalent to a small analyser rotation Strictly speaking, both Faraday cells should be placed between the quarter-wave plate and the analyser, but in order to achieve a compact instrument the compensator has been transposed to the incident beam This reduces the compensator sensitivity referred to the analyser somewhat and would be unacceptable if compensation of more than about a degree is required

In use the instrument is first adjusted by setting the plane of polarization of the incident light to be at 45° to the plane of the incident and reflected rays With a typical specimen in position the analyser and the quarter-wave plate are adjusted in turn for the best minimum photo-cell current For all further measurements with this type of specimen, the quarter-wave plate is left fixed. Measurements of film thickness are now made by first adjusting the analyser for an accurate null using the Faraday modulator and the usual electronic circuits for phase-sensitive de-modulation of the resulting photomultiplier signal After removing the film the specimen is replaced in exactly the same position and the null is re-established by direct current in the Faraday compensator This current is proportional to thickness for a given film and substrate for films thin enough for the approximate Drude equations to apply, say to at least 100 Å

	205			–285		490
	225				–395	620
	215				–405	620

In this instrument modulation is carried out at 50 c/s and the modulator produces an angular swing of about ± 2° Compensation is possible over a range of about 0 75° referred to the analyser, and the noise-level using a tinplate specimen and about 0 1 c/s equivalent band-width in the de-modulator filter is equivalent to about 3 millidegrees, and this is the limiting factor in setting the instrument This is about an order of magnitude worse than that reported by Gillham for his polarimeter and is mainly due to the poor quality, optically speaking, of commercial tinplate surfaces None the less, it is very adequate for measuring films, such as oil on tinplate, which typically produce a shift of 0 3° and is nearly an order of magnitude better than the repeatability of setting claimed by Murray

To illustrate that the instrument is responsive to the thin films of oil on tinplate (of the order of 30 Å) a piece of commercial tinplate was de-oiled and oiled a number of times, compensator readings on the ellipsometer being taken at each stage

De-oiling was by Soxhlet extraction in benzene and oiling was by dipping in and controlled slow removal from dilute solutions of oil (dioctyl sebacate) in benzene The amount of oil so deposited can be varied in an approximate manner by changing the oil concentration The results are shown in Table 1 in terms of milli-degrees of compensation Ten milli-degrees is equivalent to about one angstrom unit of oil film thickness The changes in the de-oiled state represent a slight lack of reproducibility of the surface rather than instrumental error

I thank Prof A B Winterbottom for his advice and the Metal Box Co , Ltd , for permission to publish this communication

METEOROLOGY

Measurement of Conducted Flow of Heat in a Sea Ice Cover

In any micro-meteorological study or heat economy survey, the measurement of the conducted flux of heat at, or below, the Earth's surface is important The two methods normally used to achieve this either involve measuring the temperature gradient if the thermal conductivity can be accurately established, or insertion of a heat flux meter, the basis of which is the measurement of temperature gradient across a thin slab of material of known conductivity The accuracy of heat flux meters is limited unless the effective conductivity of the device used matches that of the medium in which the flow of conducted heat is being measured For example, in using a flux meter with square horizontal surfaces with a width to thickness ratio of 12 1, a 20 per cent mismatch in conductivities results in an approximately 5 per cent error in indication

For surface media which are subject to changes in thermal conductivity or are transparent to radiation, one or other of the foregoing methods of heat flow measurement become inapplicable The first difficulty is met when rainfall alters the effective conductivity of soils or porous rocks so that measuring techniques are restricted to use of a flux meter Snow and ice covers, on the other hand, present problems due to the penetrating visible radiation heating the sensor surfaces unequally In the case of fresh-water ice, the properties of which remain essentially constant, the problem is solved by measuring the temperature gradient with small thermocouples having reflecting surfaces

Sea ice presents an example of the most complex type of situation where both problems of variability in thermal conductivity and transparency to radiation have to be considered I was able to overcome both these difficulties during a heat budget study on annual sea ice in Hudson Bay This was achieved by excavating a pit of about 1 5 m across and 25 cm deep and allowing cold fresh-water to freeze, forming a reference block Frozen into this block were a vertical sequence of four small thermocouples with reflecting surfaces electrically insulated by thin tubular polythene envelopes and spaced 5 cm apart by a transparent 'Perspex' frame The relatively thick slab of prepared ice was used to gain sufficient temperature difference to avoid the necessity for thermopiles, the increased area of which would have resulted in more serious local absorption of radiation The four thermocouples enabled a uniform temperature gradient to be detected in the reference ice, under which conditions the most widely separated thermojunctions could be used to determine the heat flux most accurately

Some optical and conductive matching between the reference block and the surrounding sea ice was accomplished during the preparation of the former By insulating the prepared excavation from above, the reference ice was made to grow from below and form a relatively dense and transparent medium On the other hand, permitting the ice to form from above, progressively in layers, resulted in a bubbly mass of small crystal structure An alternative method which proved satisfactory in controlling the density of the block was to freeze varying mixtures of snow and water Ice of a given density appeared to be more opaque when prepared by the latter method Although there was some degree of independent control over thermal conductivity and transparency, relatively accurate matching was attempted only for the former, and was checked by a determination of the conductivity of the surrounding sea ice Transparency matching was judged by appearance only, but if necessary could be checked by means of a simple light meter. Usually, a light snow cover results in radiation penetration being of reduced importance

Measurement of the thermal conductivity of the reference ice is necessary It will be shown elsewhere[1] that a simple measurement of density is sufficient to fix the conductivity of non-saline ice and that the additional determination of salinity enables the thermal conductivity of sea ice to be specified as a function of temperature The device proved to be satisfactorily sensitive and accurate and its properties, in marked contrast to those of the sea ice, remained essentially constant over a period of three months, in particular no significant diffusion of sea ice brine into the reference ice occurred The sensitivity of the 'ice heat flux meter' was demonstrated by the fact that the indicated values of surface heat flux were reflected in corresponding rates of sea ice growth after a calculable time delay[2]

GEOLOGY

Age of the Great Dyke of Southern Rhodesia

The isotopic composition of strontium has been determined for two whole-rock specimens of gabbro from the Wedza Complex of the Great Dyke of Southern Rhodesia In addition, concentrations of rubidium and strontium were measured for these rocks by the method of isotope dilution These results led to an estimate of the time since differentiation of this intrusive

The rock specimens were obtained through the courtesy of Dr B G Worst, who has made a detailed study of the structure and petrogenesis of the Great Dyke[1] He concluded that the 'Dyke' is in reality a downfaulted remnant of an original sheet-like mafic intrusive composed of four complexes and may be related to the igneous cycle of the Bushveld Igneous Complex

The isotope ratio determinations for strontium were made in duplicate on a mass spectrometer featuring a 6-in radius of curvature, 60° sector analyser tube The details of the analytical procedure have been discussed by Faure and Hurley[2] and will not be repeated here The measured $^{87}Sr/^{86}Sr$ ratios were normalized to a standard value for $^{86}Sr/^{88}Sr = 0\ 1194$ by a procedure outlined by Faure and Hurley[2,3] In addition, a correction of $-0\ 003$ was applied to the $^{87}Sr/^{86}Sr$ ratios in order to eliminate a consistent bias from the results as indicated by replicate analyses of a secondary strontium isotope standard ($SrCO_3$, Eimer and Amend, lot 49232, Table 1).

The rubidium determinations were made in duplicate by isotope dilution while the strontium determinations were confirmed by X-ray fluorescence analysis The analytical results are summarized in Table 1

Table 1 ANALYTICAL DATA FOR THE GREAT DYKE, SOUTHERN RHODESIA

M I T sample	rock type	$\frac{^{87}Sr}{^{86}Sr}$	$\frac{^{86}Sr}{^{88}Sr}$	$\left[\frac{^{87}Sr}{^{86}Sr}\right]_{corr}$	Rb (p p m)	Sr (p p m)	$\frac{^{87}Rb}{^{86}Sr}$
4937	Quartz gabbro/ Wedza complex	0 7212	0 1199	0 7227	34 6	153 9*	
		0 7232	0 1189	0 7217	31 0		
	Average	0 7222 ± 0 0010	0 1194 ± 0 0005	0 7222 ± 0 0005	32 8 ± 5 5%	153 9 ± 5%	0 617 ± 0 046
4936	Norite/ Wedza complex	0 7059	0 1193	0 7056	6 38	245 0*	
		0 7048	0 1192	0 7042	5 16		
	Average	0 7054 ± 0 0005	0 1193 ± 0 0001	0 7049 ± 0 0007	5 77 ± 10 7%	245 0 ± 5%	0 068 ± 0 008

The measured $^{87}Sr/^{86}Sr$ ratios were corrected for isotope fractionation assuming that $^{86}Sr/^{88}Sr = 0\ 1194$ (see ref 2)

Blank corrections of 0 234 μg Sr and 0 10 μg Rb were made to all isotope dilution analyses

* Confirmed by X-ray fluorescence analysis using a norite of known Sr content (by isotope dilution) as comparison standard Sample 4937, Sr = 155 p p m , sample 4936, Sr = 241 p p m

$SrCO_3$, Eimer and Amend, lot 492327, average of nine analyses on one instrument $^{87}Sr/^{86}Sr = 0\ 7084 \pm 0\ 0007(\sigma)$, corrected relative to $^{86}Sr/^{88}Sr = 0\ 1194$

The time elapsed since differentiation of the two rock specimens was calculated by solving two simultaneous equations of the form

$$\left[\frac{^{87}Sr}{^{86}Sr}\right]_p = \left[\frac{^{87}Sr}{^{86}Sr}\right]_0 + \frac{^{87}Rb}{^{86}Sr}(e^{\lambda t}-1)$$

where

$\left[\frac{^{87}Sr}{^{86}Sr}\right]_p$ = atomic ratio of ^{87}Sr to ^{86}Sr at the present time

$$\left[\frac{^{87}Sr}{^{86}Sr}\right]_0 = \text{same at } t = 0$$

$$\lambda = 1\ 47 \times 10^{-11}\ yr^{-1}$$

The solution of the two equations yields $t = 2{,}110 \pm 350$ m y and $\left[\frac{^{87}Sr}{^{86}Sr}\right]_0 = 0\ 7028 \pm 0\ 0013$ The errors assigned are uncertainties and include maximum and minimum values compatible with the analytical results The large uncertainty of ± 17 per cent assigned to the age is partly due to the fact that the radiogenic ^{87}Sr enrichment of sample No 4937 is only about 2 5 per cent relative to the initial abundance of this isotope This work is the first attempt, to the best of our knowledge, to determine the time since differentiation of the Great Dyke of Southern Rhodesia by radioactive dating techniques

Nicolaysen *et al* [4] reported a rubidium–strontium age of 1,940 ± 50 million years (recalculated to $\lambda = 1\ 47 \times 10^{-11}\ yr^{-1}$) for the mafic rocks of the Bushveld Complex of the Republic of South Africa This determination was made on a biotite concentrate from a biotite bearing pyroxenite of the Rustenburg Platinum Mine Nicolaysen *et al* [4] concluded from their data that " new age measurements on micas, monazites and zircons from the Bushveld Complex are consistent with an age of 1,950 ± 150 million years " Schreiner[5] was the first to report age determinations by the whole-rock rubidium–strontium method His age for the red granite which intrudes the mafic rocks of the Bushveld Complex is 1,800 m y (recalculated to $\lambda = 1\ 47 \times 10^{-11}\ yr^{-1}$)

The age of the Great Dyke of Southern Rhodesia is 2,110 ± 350 million years and is therefore identical within the limits of the errors to the age of the Bushveld Igneous Complex This conclusion supports the earlier suggestion by Worst[1] that the Great Dyke and the Bushveld Complex were emplaced during the same magmatic cycle

We thank Dr B G Worst for sending us the whole-rock specimens of the Great Dyke This work was supported by the U S Atomic Energy Commission contract *AT*(30–1)–1381

Geology of the East Rutts (South Devon)

AN expedition by the Oxford Underwater Research Group was made during July 1963 to examine the submerged pinnacle of rock known as the East Rutts (50° 13 5′ N , 3° 59′ W)

The rock is situated five miles south-west of the Bolt Tail promontory and 5 6 miles south of St Anchorites Rock in Bigbury Bay

It is approximately elliptical in plan, being about 530 yd in length in a north-east–south-west direction and 220 yd in a north-west–south-east direction Echo-sounding traverses indicated that the uppermost part of the pinnacle lay about 30 ft below the surface whereas the sea-floor in the vicinity of the rock lay at 120 ft

Extensive gullies were seen to cut through the rock formation in a north-east–south-west direction, and an almost sheer face was observed at the south-west end of the pinnacle

Samples of the rock *in situ* were obtained by aqualung divers of the Group and were subjected to petrological examination, X-ray and chemical analysis

In thin-section the rock shows a mainly anhedral mosaic of dolomite grains with some calcite enclosing lenses and stringers of strained quartz grains Clustering of the dolomite grains at the edge of the quartz and the presence of dolomite rhombs in the quartz patches suggest diagenetic replacement Specimens from a depth of 50 ft are finer-grained (average grain size diameter 0 1 mm) than those from 100 ft (average grain size diameter 0 5 mm), rare small flakes of mica are present in the former and more extensively in the latter, together with a little anhedral iron ore

An X-ray powder photograph showed the presence of quartz, dolomite, calcite, mica and ore.

A chemical analysis of the rock from a depth of 100 ft is given It compares closely with the analysis of the Knox dolomite from Morrisville, Alabama, U S A , quoted by Pettijohn (1956, Table 81, Analysis *D*) except in its somewhat higher silica content

Analysis

	%
SiO_2	8 47
R_2O_3	0 59
MgO	18 07
CaO	28 32
CO_2	42 39
Na_2O	1 07
K_2O	0 97
H_2O (110° C)	0 31
Total	100 19

Neutron activation analysis of the rock indicated 19 7 ± 0 68 per cent for its magnesia content

The presence of a large mass of dolomite in the East Rutts area is surprising, considering the present stratigraphic and structural ideas on that part of the English Channel Hill and King[1] indicate the presence of metamorphic rocks in the locality, with New Red Sandstone deposits to the north and west, the latter giving place to the metamorphic rocks comprising the Eddystone reef Apart from presenting the evidence of the existence of the dolomite we have as yet no explanation to offer for its position other than the very tentative suggestion that it may be a very localized facies of the Devonian or of New Red Sandstone lying within the Eddystone–Start Point metamorphic thrust zone It is hoped that further investigations now planned will provide more evidence

We thank Mr A Stone, of the Neutron Generator Laboratory, Wantage Research Laboratories, for checking the magnesia content of the rock by neutron activation analysis We also thank Dr K Sandford, of the Department of Geology and Mineralogy, University of Oxford, for helpful discussions, and Mr A Hancock and Mr D Gill for the collection of *in situ* samples of rock under arduous diving conditions

Local Distribution of Elements in the Tests of Foraminifera

Electron probe X-ray microanalysis permits the determination on a micro-scale of local distribution and concentration of elements in a sample In a preliminary enquiry, the tests of calcareous Foraminifera have been investigated

The analysis was preceded by optical emission spectrographic analysis of the tests of approximately 12 specimens of each species investigated These analyses determined the elemental composition of the tests plus included sedimentary particles which cannot (with certainty) be cleaned out of the innermost chambers The results of the spectrographic analyses were used to eliminate the necessity of preliminary searching on the electron probe, thus saving much time

Foraminifera for probe analysis were cleaned in dilute hydrogen peroxide After drying, they were embedded (under partial vacuum) in polystyrene The method of embedding is described in detail by me (submitted for publication) A median section was cut and polished, and a thin metal layer was deposited on it by vacuum evaporation, to ensure electrical continuity

Generally, interpretation of results was complicated by topographical and microstructural effects The calcium and silicon concentration variation in Recent *Elphidium excavatum* (Terquem) and *E bartletti* (Cushman), calcium concentration variation in Recent *Quinqueloculina seminulum* (L), calcium, iron, silicon, manganese, and magnesium concentration variation in the Tertiary *Operculina victoriensis* (Chapman and Parr), and calcium and magnesium concentration variation in Recent *Operculina complanata* (Defrance) have been recorded

Improved magnesium detection is desirable, because this element has been shown to be of classificatory and ecological significance in the Foraminifera

METALLURGY

Effect of Impurities on the Electrical Resistivity Increase during Elongation of Cadmium at 71° K

Observations of electrical resistivity increases in metals during plastic deformation[1] have been attributed to changes in the concentration of point, line and planar defects Further experiments have demonstrated that prior deformation and recovery[2] as well as impurity concentration[3,4] affect the slope of the resistivity–elongation curves It is the purpose of this communication to present some results obtained on cadmium containing impurities The influence of lead, magnesium and copper, in particular, is discussed

Polycrystalline cadmium wire, which for most experiments was 1 mm in diameter, was obtained in various degrees of purity as indicated in Table 1 Specimens, about 14 cm long, were elongated in liquid nitrogen and the resistance change was measured potentiometrically as a function of elongation A more detailed description of the experiment is available in ref 5

Table 1 Emission Spectrograph Analysis of Cadmium Impurities (p p m)

Sample impurity	69-Cd + 1,000 p p m Pb	69-Cd + 1,000 p p m Mg	69-Cd + 10 p p m Cu	Commercial Cd	49-Cd	59-Cd
Pb	1,000	<1	<1	100	3	<1
Mg	<1	1,000	<1	<1	10	<1
Si	<1	<1	<1	<1	10	<1
Fe	<1	<1	<1	<1	10	<1
Cu	10	10	10	10	3	<1
Ag	<1	<1	<1	3	10	<1
Al					10	
Total impurities (nominal)	1,000 p p m Pb 10 p p m Cu	1,000 p p m Mg 10 p p m Cu	10 p p m Cu	110 p p m	56 p p m	1 p p m
Slope (approx)	<3 4	3 4	3 4	1 8	1 2	3 4

The results of the deformation experiments at liquid nitrogen are shown in Fig 1 The closed and open squares represented by curves *A* and *B* are data on the same 59-cadmium specimen measured while the load was on and after the load was removed, respectively Part of the difference between *A* and *B* can be attributed to the elastic recovery, which is estimated to be less than 0 1 per cent However, the greater part of the difference is undoubtedly due to the presence of the stress and its subsequent effect on the scattering of conduction electrons It can be seen that both *A* and *B* show a linear dependence on strain The results for cadmium doped with copper, lead and magnesium also fall on curve *B* although the cadmium containing lead shows some deviation Curve *C*

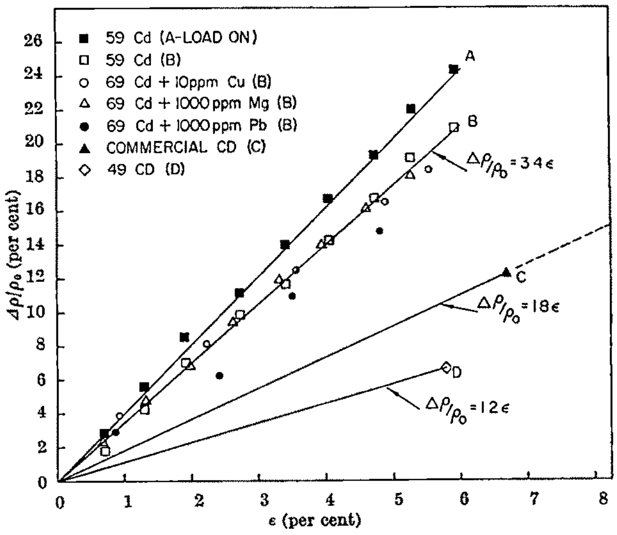

Fig 1 Percentage resistivity increase for cadmium specimens of various purities as a function of elongation strain at 78° K

shows some results obtained earlier in this laboratory for cadmium of commercial purity These latter specimens were 5 mm in diameter and their resistance was measured using a Kelvin double bridge Only one point of this data is shown on Fig 1 Other results obtained from this experiment indicate a linear behaviour to approximately 13 per cent elongation The point on curve *D* represents the average data of eighteen 49-cadmium specimens The deviation from the average value noted on the plot is insignificant

It is interesting to note that the addition of slight amounts of copper has very little influence on the ρ versus ε curves over what is observed for high-purity cadmium Additional impurities such as magnesium, at least at a concentration of 1,000 p p m , shows no effect Lead however, does affect the slope of these curves As the lead concentration increases, the slope decreases from that observed for high-purity cadmium and then increases toward the high-purity slope as the lead concentration approaches 1,000 p p m

The effect of other impurities such as silicon, iron, silver and aluminium is not very clear Nevertheless, the 49-cadmium contains all these elements and does have the lowest ρ versus ε slope Whether it is primarily the lead or these other elements which is influencing this behaviour must await further investigation

It is recognized that impurities in copper and other metals influence defect formation such as stacking faults It can be speculated that the behaviour noted in cadmium is associated with twin formation, stacking faults, dislocation multiplication, influence of impurities on preferred orientation, etc Obviously, a more complete investigation is necessary to elucidate this phenomenon

Elevated Temperature Embrittlement induced in a 20 per cent Chromium : 25 per cent Nickel : Niobium Stabilized Austenitic Steel by Irradiation with Thermal Neutrons

IT has been known for some time that neutron irradiation at ambient temperatures produces increases in the proof and ultimate tensile stresses and reductions in ductility of austenitic steels in room temperature tensile tests[1] These changes in properties result from the interaction of dislocations with the vacant lattice sites and interstitial atoms produced by fast neutron-atom collisions and are recovered on testing at temperatures of about 500° C due to annihilation of the point defects[2]

More recently it has been established that irradiation in a nuclear reactor also reduces the ductility of austenitic steels and austenitic type alloys at test temperatures above about 600° C. This high-temperature brittleness is manifested as decreases in the elongation and reduction of area values in post-irradiation uniaxial tensile tests[3], reduced strengths and elongations in post-irradiation stress rupture tests[4] and reductions in the circumferential elongations to fracture in 'in-pile' tube bursting tests[5]

The mechanism responsible for this type of embrittlement is being investigated in a double-vacuum-melted 20 per cent chromium 25 per cent nickel niobium stabilized steel, the analysis of which is given in Table 1

Table 1 ANALYSIS OF STEEL

Element	C	Cr	Ni	Mo	Nb	Ti	Cu

Wt %	0 03	0 008					

Tensile specimens with a parallel gauge-length of 0 835 in were die-stamped from a strip 1 in wide and 0 0215 in thick and heat-treated for 0 5 h at 1,050° C in pure argon followed by rapid cooling The specimens were electropolished and individual batches were irradiated as follows (1) at 40° C in the core of the *Herald* light-water moderated and cooled reactor; (2) at 135° in the 4VGR hole, (3) at 50° C in the 2V hole in the *Dido* heavy-water moderated and cooled reactor Cobalt and nickel monitors were included with each batch of specimens to measure the thermal and fission neutron doses respectively The specimens were afterwards tested at room temperature, 750° or 850° C at a strain rate of 2×10^{-4} sec^{-1} in a hard beam autographically recording dynamometer tensile machine operated remotely within a 4-ft thick concrete cell, the elevated temperature tests were made in purified argon and the temperatures were stabilized for 0 5 h before commencing the tests At least two specimens were tested in each condition and the mean results of the 750° and 850° C tests are given in Table 2

Table 2 ELEVATED TEMPERATURE TENSILE TEST RESULTS ON UNIRRADIATED AND IRRADIATED 20 PER CENT CHROMIUM 25 PER CENT NICKEL NIOBIUM STABILIZED AUSTENITIC STEEL

Irradiation facility	Neutron dose (n cm^{-2})		Test temperature (° C)	0 2% Proof stress (lb /in ^{2})	Ultimate tensile stress (lb /in ^{2})	% Elongation
	Thermal	Fission				
—	—	—	750	18,200	27,600	55 5
Herald	$7\,6 \times 10^{18}$	$3\,8 \times 10^{18}$	750	18,500	26,400	48 3
Dido 4VGR	$2\,2 \times 10^{19}$	$1\,9 \times 10^{16}$	750	16,400	27,200	29 1
Dido 2V	$1\,5 \times 10^{20}$	$7\,4 \times 10^{17}$	750	14,600	27,800	17 9
—	—	—	850	13,200	14,200	56 4
Herald	$7\,6 \times 10^{18}$	$3\,8 \times 10^{18}$	850	13,100	14,400	41 1
Dido 4VGR	$2\,2 \times 10^{19}$	$1\,9 \times 10^{16}$	850	14,600	15,800	38 6
Dido 2V	$1\,5 \times 10^{20}$	$7\,4 \times 10^{17}$	850	13,100	15,300	20 8

With the possible exception of the 0 2 per cent proof stresses of the samples tested at 750° C, the stress values are not significantly affected by the irradiation; however, the elongations to fracture are markedly reduced at both test temperatures This elevated temperature embrittlement is a function of the thermal neutron dose and cannot be correlated with the fission (or fast) neutron dose This is in contrast to the room temperature point defect hardening and embrittlement which is dependent on the fast neutron dose as shown in Table 3

Table 3 ROOM TEMPERATURE TENSILE TEST RESULTS ON UNIRRADIATED AND IRRADIATED 20 PER CENT CHROMIUM 25 PER CENT NICKEL NIOBIUM STABILIZED AUSTENITIC STEEL

Irradiation facility	Irradiation dose (n cm^{-2})		0 2% Proof stress (lb /in ^{2})	Ultimate tensile stress (lb /in ^{2})	% Elongation
	Thermal	Fission			
—	—	—	30,700	76,800	48 2
Dido 4VGR	$2\,2 \times 10^{19}$	$1\,9 \times 10^{16}$	37,500	84,600	42 2
Dido 2V	$1\,9 \times 10^{20}$	$1\,7 \times 10^{18}$	48,100	84,700	30 2
Herald	$7\,6 \times 10^{18}$	$3\,8 \times 10^{18}$	54,500	89,000	31 6

Additional experiments are in progress to confirm these observations and to investigate the mechanism whereby the thermal neutrons are effective in causing the elevated temperature embrittlement of austenitic steels

We thank Mr J Fennell for assistance with the testing of the specimens

Equilibrium Diagram for the Nickel-Cadmium System

To study the effect of size factor in alloying behaviour it was decided to determine the ternary system Cu–Ni–Cd, on which no data have been published The binary systems Cu–Ni and Cu–Cd have been fully investigated, the results of the various investigations being summarized by Hansen[1] Of the Ni–Cd system only cadmium-rich alloys have been studied in detail a further investigation of this system was therefore carried out in conjunction with the work on the ternary diagram

Alloys were prepared from analytical reagent quality nickel powder and stick cadmium, the powder was given a reducing treatment in hydrogen to remove any oxide present Weighed amounts of the pure metals were sealed in evacuated silica capsules for melting, which was carried out by heating for about 1 h at 1,200°–1,250° C, conditions which had been shown to be adequate for the nickel to be taken into solution The capsules were then rapidly cooled to give a fine-grained ingot and annealed for a minimum period of three weeks to homogenize the alloy At the end of the annealing period the alloys were water-quenched and then weighed to check whether any loss had occurred in melting The nominal compositions of ingots which were satisfactory in this respect were taken as the actual compositions

The liquidus surface for the Ni–Cd systems was examined by equilibrating nickel in the form of wire with cadmium at constant temperature At the end of the soaking period the capsule containing the sample was quenched and broken open The residuum of the wire was separated from the melt and the latter analysed for its nickel content The results obtained from this study are indicated in Fig 1 Cooling curves on alloys close to 50 atom per cent nickel failed to show any arrest between the liquidus and 502° C, micro-examination of these cooling curve ingots showed the formation of peritectic walls of β Ni–Cd surrounding dendrites of the α-phase The peritectic temperature was therefore determined from heating curves on homogenized alloys and gave a value of 695° C for the decomposition temperature of the β phase The formation of the γ′ phase was studied by combined dilatometry and thermal analysis The volume change at 405° reported by Voss[2] was not observed, an alloy of γ′ together with a small amount of γ showed an arrest point accompanied by partial collapse of the specimen at 490° C and a second arrest and complete collapse at 502° C It is significant that Voss, who reported a peritectic temperature of 502°, obtained this value on higher nickel content alloys (~10 wt per cent nickel) than Swartz and Phillips[3] (6–8 wt per cent nickel), and it is probable the former detected the peritectic involving γ′ and the latter that of γ, which would be more prominent in the lower nickel alloys they studied The nickel-rich solubility limit is confirmed by an alloy of 21 2 atom per cent nickel, which showed the presence of a trace amount of γ′ at 430° C compared to a reported solubility of 19 5 atom per cent at this temperature Other than the β-phase (Ni–Cd) no other compounds were observed in the system

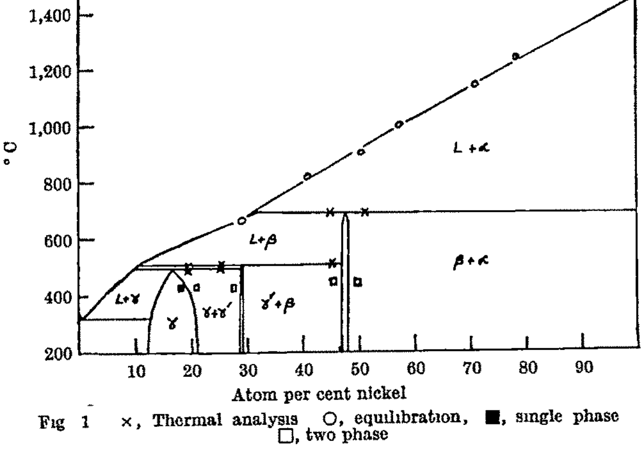

Fig 1 ×, Thermal analysis ○, equilibration, ■, single phase □, two phase

The β-phase structure has been studied by X-ray diffraction using the powder method The compound possesses the structure $Fd3m$ with a cell edge of 11 40 kX units and contains approximately 48 formula units in the unit cell

CHEMISTRY

Spin-orbit Coupling and Intermolecular Energy Transfer

Recently[1,2] we reported on the intermolecular energy transfer in chemiluminescent solutions, an excited product of the reaction being a donor and anthracene derivatives being acceptors (activators) The activated chemiluminescence spectra were identical with the fluorescence spectra of the activators, indicating that the singlet state of the activator is the excited one[2] A dependence of the chemiluminescence intensity on the activator concentration was used for estimating the ratio k_{PA}/f_P (k_{PA}, transfer constant, f_P, emission probability of the excited product, P' (Fig 1)) The relative values of the k_{PA}'s were found to be greater the more halogens were introduced in the activator molecule and the greater was the atomic weight of the substituent In this communication these features of the phenomenon are regarded as evidence for the spin-orbit coupling in the activator molecule

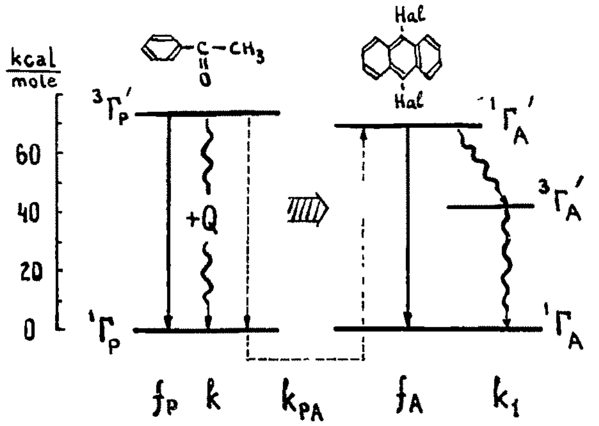

Fig 1 Energy-levels diagram for the chemiluminescence in ethylbenzene oxidation and for the energy transfer on the anthracene derivatives The solid, waved and dashed lines represent, respectively, radiative, radiationless transitions and energy transfer Deactivation by a quencher, Q, is discussed in ref 3

The excited product P' formed in the hydrocarbon oxidation was identified as a ketone in its triplet state[3] Therefore, the energy transfer may be represented as a coupled transition $|{}^3\Gamma'_P \rightarrow {}^1\Gamma_P| \rightarrow |{}^1\Gamma_A \rightarrow {}^1\Gamma'_A|$, as shown in Fig 1 There were reasons for considering it as an exchange-resonance transfer—its features strongly differed[2] from those required by the theories of the inductive-resonance or radiative transfer, and the maximum value of k_{PA} (for 9,10-di-bromoanthracene) was only 20–30 times less than the number of collisions So we believe that the

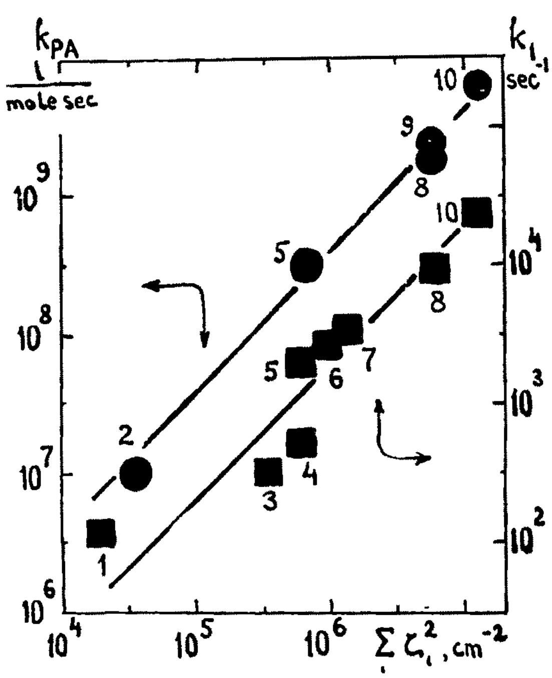

Fig. 2. Substituents influence on probabilities *T-S* intra- and inter-molecular transitions. k_1—from ref. 6, k_{PA}—from ref. 2—assuming f_P for *cyclo*hexanone equal to 10^3 sec^{-1}. *Cyclo*hexanone is formed in *cyclo*hexane oxidation at 50° C. The straight lines correspond to direct proportionality between the abscissas and ordinates. Values of ζ_i from ref. 5. 1, Anthracene (*A*), 2, 9,10-diphenyl-*A*, 3, 1-chloro-*A*, 4, 1,5-dichloro-*A*, 5, 9,10-dichloro-*A*, 6, 2,9,10-trichloro-*A*, 7, 1,5,9,10-tetrachloro-*A*, 8, 9-bromo-*A*, 9, 9-bromo,10-phenyl-*A*, 10, 9,10-dibromo-*A*

energy transfer is brought about by the exchange of electrons between the donor and acceptor in the state of a diffusion-controlled collision. Then its probability should be proportional to the matrix element squared of the operator of the exchange interaction[4]

$$k_{PA} \sim |<H_1>|^2 = |\int \psi'_P{}^*(1)\psi_A{}^*(2)H_1\psi'_A(1)\psi_P(2)d\tau|^2 \quad (1)$$

$$H_1 = e^2/r_{12}$$

$<H_1>$ is not equal to zero except when the excited donor and acceptor have the same multiplicity and their normal states have the same multiplicity also[4]. This selection rule is obviously not valid in our case since the excitation is transferred from the triplet state to the singlet one, that is

$$\psi'_P = {}^3\psi'_P \text{ and } \psi'_A = {}^1\psi_A$$

For that reason $<H_1>$ and k_{PA} are close to zero and the transfer is 'forbidden'.

Introduction of halogens strengthens an interaction of the spin and orbital momenta. That leads to the 'mixing' of states of different multiplicity

$$\psi'_A = {}^1\psi'_A + \lambda\,{}^3\psi'_A \quad (2)$$

Combination of equations (1) and (2) leads to the following expression

$$k_{PA} \sim \lambda^2|<H_1>|^2_{3,3} \quad (3)$$

where $|<H_1>|_{3,3}$ is the part of the $|<H_1>|$ corresponding to the 'pure' triplet–triplet transition

$$|<H_1>|_{3,3} = \int {}^3\psi'_P{}^*(1)\,{}^1\psi_A{}^*(2)H_1\,{}^3\psi'_A(1)\,{}^1\psi_P(2)d\tau$$

Now the coupled transition becomes permissible and hence the greater becomes factor λ. The latter may be calculated in principle by the methods of the perturbation theory of quantum mechanics

$$\lambda = \frac{<H_{so}>}{\Delta E} \quad (4)$$

where $<H_{so}>$ is the matrix element of the spin-orbit operator and ΔE, energy difference for levels ${}^1\Gamma'_A$ and ${}^3\Gamma'_A$. A precise calculation of λ is difficult and I considered a simplified model of the activator molecule assuming that it consists of 'isolated' atoms, each of them independently influencing the excited electron. In this approximation, a contribution of each atom into k_{PA} may be represented by ζ_i^2, where ζ_i is a radial part of the matrix element $<H_{so}>$ for an isolated atom—a quantity well known from atomic spectra[5]. Hence k_{PA} should be proportional to $\sum_i \zeta_i^2$. In fact this correlation takes place for a number of anthracene derivatives, as is shown in Fig. 2.

It is remarkable that, according to Hoffman and Porter, halogen-induced spin-orbit coupling increases the probability of the intramolecular radiationless transition ${}^3\Gamma'_A \rightarrow {}^1\Gamma_A$ in the anthracene derivatives[6]. The probability of this triplet–singlet conversion may be written in the form

$$k_1 \sim |<H>|^2 = |\int {}^3\psi'_A{}^* H\,{}^1\psi_A d\tau|^2 \quad (5)$$

where H is a certain operator which depends on transition mechanism (for example, for dipole–dipole radiative transition H is the dipole momentum operator). $<H>$ is equal to zero in the absence of the spin-orbit coupling. On the analogy with the aforementioned energy transfer quantities, $|<H>|^2$ and k_1 should be proportional to the same quantities $\sum_i \zeta_i^2$ for halogen derivatives of anthracene. This correlation is also satisfactorily carried out as can be seen from Fig. 2. (At the same time, a dependence of k_1 on the position of a substituent is seen from Fig. 2 which indicates the limitations of the simple model used.) That verifies my hypothesis of the identical mechanism of halogen influence on both intra- and inter-molecular processes.

Considering the possibilities of chemiluminescence as a method of studying excited states I should like to emphasize some positive characteristics of this way of excitation. If I had used photo-excitation it would be very difficult to study the energy transfer from a poorly luminescent donor (ketone) on to a well luminescent activator because of the unavoidable direct excitation of the activator which is strongly absorbing in the spectral region common with the donor. In the case of chemical luminescence, excited states are being formed by 'dark' way and the strongly luminescent components can be excited only through energy transfer, the latter being a subject of the present investigation.

Vaporization of Uranium Monophosphide

IN the search for new oxygen-free refractory materials, we have found that the subphosphide of thorium, $ThP_{0.7}$, has a high thermodynamic stability[1] which is comparable with that of uranium monosulphide[2]. We have included the uranium monophosphide, UP, and its mixtures with uranium dioxide in our investigations[3]. Since recent reports[4,5] indicate the potential usefulness of uranium monophosphide for high-temperature reactor application, we present here our preliminary results concerning the thermodynamics of vaporization of uranium monophosphide.

The uranium monophosphide was prepared by reaction of the elements using the Faraday method and thermally degrading the resulting triuranium tetraphosphide, U_3P_4, to uranium monophosphide at 1,400° C. Analysis showed that it contained 0.38 per cent oxygen. An X-ray diffraction pattern showed the presence of uranium monophosphide and traces of uranium dioxide. The mass spectrometric investigation was done with an instrument at the National Bureau of Standards similar to that described by Chupka and Inghram[6]. A tantalum Knudsen effusion cell with a tungsten liner was used. Temperatures were measured with a calibrated optical pyrometer under black-body conditions.

The vaporization of uranium monophosphide was investigated over the temperature range from 1,750°–2,250° K. During its vaporization the major primary ion species observed and measured were U^+, P^+, P_2^+, and UO^+. In a uranium monophosphide–uranium dioxide mixture, the UO_2^+ ion was also a major species. In no case was gaseous uranium monophosphide observed. X-ray analysis of the residue left in the effusion cell from the uranium monophosphide samples showed only lines of uranium monophosphide. Lines of uranium dioxide could no longer be detected. On the basis of these observations, we suppose that uranium monophosphide vaporizes congruently over the temperature-range measured according to the following reaction:

$$UP_{(s)} = U_{(g)} + \frac{1}{x} P_{x(g)} \; (x = 1 \text{ or } 2) \qquad (1)$$

Oxygen impurities in the uranium monophosphide sample are believed to react according to

$$UP_{(s)} + UO_{2(s)} = 2UO_{(g)} + \frac{1}{x} P_x \; (x = 1 \text{ or } 2) \qquad (2)$$

The observations that no uranium dioxide could be detected in the residue and that the UO^+ ion intensity decreased in relation to the U^+ ion intensity as the vaporization progressed indicate that reaction (2) is preferred to reaction (1). If the uranium dioxide content becomes large, reaction (2) becomes the predominant reaction. The appearance of the UO_2^+ ion resulting from the vaporization of uranium dioxide according to

$$UO_{2(s)} = UO_{2(g)} \qquad (3)$$

is also observed.

The ion intensities are correlated to vapour pressures through silver calibration[6,7]. The difference in electron multiplier efficiencies of Ag^+ and the ionic species observed above uranium monophosphide was determined experimentally. Corrections for fragmentation and double ionization were considered. The intensity of U^+ ion was corrected for the effect of oxygen content according to equation (2). For the ionization cross-section of the phosphorus monomer the value of 13.8 as given by Otvos and Stevenson[8] was used. For the phosphorus dimer the value 21.8 was estimated. A value of 37.5 was derived for the cross-section of uranium on the basis of congruency of vaporization according to equation (1) using the cross-section of the phosphorus monomer as a standard.

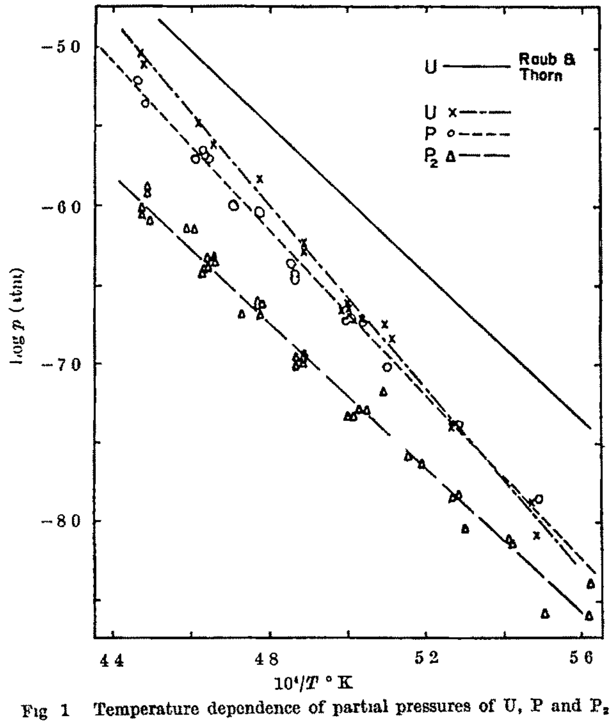

Fig. 1. Temperature dependence of partial pressures of U, P and P_2

In Fig. 1 the logarithm of the vapour pressure of each species over uranium monophosphide is presented as a function of the reciprocal of absolute temperature. The derived average values for partial molal heats of vaporization in kilocalories per mole, at 2,000° K, are as follows: $\Delta\bar{H}$ (U) = 131.69 ± 2.25, $\Delta\bar{H}$ (P) = 119.94 ± 2.63; $\Delta\bar{H}$ (P_2) = 105.46 ± 1.66, where the uncertainties represent standard deviations. From these values a heat of vaporization, ΔH° vap., in kilocalories per mole of uranium monophosphide, is obtained as 184.42 ± 3.08 for the reaction (1) when $x = 2$ and 251.63 ± 4.88 when $x = 1$. The temperature dependence of the partial pressures over the temperature range of investigation is linear within the limits of experimental errors and can be expressed by the following equations:

$$\log p_{(\mathrm{atm})}\,[P] = \frac{-26{,}211}{T} + 6.4107 \pm 0.0716$$

$$\log p_{(\mathrm{atm})}\,[P_2] = \frac{-23{,}046}{T} + 4.2550 \pm 0.1036$$

$$\log p_{(\mathrm{atm})}\,[U] = \frac{-28{,}778}{T} + 7.7950 \pm 0.0687$$

Also included in Fig. 1 is the calculated vapour pressure of uranium[9]. Due to the different temperature dependences of the uranium pressures of solid uranium monophosphide and liquid elemental uranium, the uranium dissociation pressure of uranium monophosphide will become equal to that of elementary uranium at 2,600° K. This implies that above 2,600° K the vaporization of uranium monophosphide becomes incongruent and can be expressed by equation (1) and equations (4) and (5):

$$UP_{(s)} = U_{(l)} + \frac{1}{x} P_x \; (x = 1 \text{ or } 2) \qquad (4)$$

$$U_{(l)} = U_{(g)} \qquad (5)$$

The congruency of the vaporization below 2,600° K may need to be modified to account for a deviation from stoichiometry that increases at high temperatures[4]. Indications of this in our work are supported by the decrease in lattice parameter from 5.589 ± 0.001 to 5.584 ± 0.001 Å of uranium monophosphide during vaporization and by the observation that there is a slight decrease in total vapour pressure and a decrease in the partial pressure ratio of phosphorus monomer and uranium as the vaporization proceeds. Possible secondary reactions with the container materials have not been considered in the evaluation. From the extrapolation of the total pressure to one atmosphere, a boiling point of uranium monophosphide of 3,890° K can be predicted. For uranium mononitride the decomposition temperature is approximately 3,110° K (ref. 10). As compared with uranium monosulphide[2], the total vapour pressure of uranium monophosphide in our temperature range is lower by a factor between three and ten. Uranium monophosphide thus appears to be a refractory material of high stability. This stability against vaporization and the apparent congruency of the vaporization process add to its potential usefulness as a nuclear fuel material at high temperatures. The similarity in vaporization behaviour and density, and the expected similarity in thermal expansion may make it a promising additive to uranium dioxide base nuclear fuel elements

We thank Mr D. W Wilson for the synthesis and X-ray analysis This work was supported by the U S Atomic Energy Commission

Effect of the Compressibility of the Carrier Gas on the Experimentally Determined Number of Plates of a Chromatographic Column

THE height-equivalent to a theoretical plate of a chromatographic column, either packed or tubular, can be represented by the general equation

$$h = A + B\frac{D_g}{v} + C_g\frac{v}{D_g} + C_l\frac{v}{D_l} \qquad (1)$$

where v designates the carrier gas velocity, D_g and D_l the diffusion coefficients of the particular component considered in the carrier gas and in the fixed phase, respectively, and where A, B, C_g and C_l are appropriate constants ($A = 0$ in tubular columns)

Experimentally, when the drop in pressure in a column is small compared with the gas pressure, the number of plates in a column, operated at constant gas flow and temperature, that is, the length of the column divided by h, can be determined from the relation

$$\frac{l}{h} \cong n^* = 8\ln 2\left(\frac{t}{\Delta t}\right)^2 = 5\ 54\left(\frac{t}{\Delta t}\right)^2 \qquad (2)$$

where t and Δt designate the elution time after injection and the width of the eluted band at mid-height, respectively

When the drop in pressure is not negligibly small, the fourth term in the right-hand side of equation (1), which varies with v, that is, inversely with the pressure, will cause h to vary with the pressure If, however, this last term is negligibly small, h is independent of the pressure, since both v and D_g vary inversely with the pressure In this case, the number of plates in the column as defined here remains a well-defined quantity, but relation (2) must be modified to take care of the various effects due to the gas compressibility The calculations are as follows The velocity v at any point in the column is determined by the relation

$$v = \frac{\mathrm{d}p}{\mathrm{d}x}\frac{1}{r} = v_0 \times \frac{p_0}{p} \qquad (3)$$

where $\frac{\mathrm{d}p}{\mathrm{d}x}$ = pressure gradient, r = pneumatic resistance per unit length, v_0 = gas velocity near column exit, p_0 = pressure at exit (usually atmospheric pressure) Since r is proportional to the carrier gas viscosity, which is substantially independent of pressure, r may be regarded as constant throughout a uniform column

Integration of equation (3) gives p as a function of inlet and exit pressures, and distance from the inlet of a column of length l

$$p^2 = p_1^2 + \frac{x}{l}(p_0^2 - p_1^2)$$

The average pressure and average squared pressure in the column can be obtained immediately from the relation just written by appropriate integrations

$$\bar{p} = \frac{2}{3}\frac{p_1^3 - p_0^3}{p_1^2 - p_0^2}, \quad \overline{p^2} = \frac{p_1^2 + p_0^2}{2}$$

The time of travel of a sample for which the column has a capacity ratio k is

$$t = (1 + k)\int_0^l \frac{\mathrm{d}x}{v} = (1 + k)\frac{1}{v_0p_0}\int_0^l p\mathrm{d}x =$$
$$\frac{2}{3}\frac{1 + k}{v_0p_0}\frac{p_1^3 - p_0^3}{p_1^2 - p_0^2}\,l \qquad (4)$$

As a sample packet is carried along the column from higher to lower pressures, its second moment (variance) is increased by the combined effects of diffusions and isothermal expansion This latter effect can be equated out of the mathematical treatment by considering the specific second moment of mass, w, an increment of which is given by

$$\mathrm{d}w = p^2\ \ \mathrm{d}u = p^2h\mathrm{d}x$$

since a sudden isothermal expansion of a gas packet leaves w invariant Integration over the entire column length gives

$$w = h\int p^2\mathrm{d}x = h\,\frac{p_1^2 + p_0^2}{2}\,l$$

At the column exit, w is related to the observed bandwidth at mid-height by

$$\Delta t^2 = 5\ 54\ (1 + k)^2\,\frac{w}{p_0^2v_0^2} =$$
$$5\ 54\ (1 + k)^2\,\frac{p_1^2 + p_0^2}{2p_0^2v_0^2}\,lh \qquad (5)$$

Equations (2), (4) and (5) give for n^* as a function of the actual number of plates, $n = \frac{l}{h}$

$$n^* = \frac{8}{9}\,\frac{(p_1^3 - p_0^3)^2}{(p_1^2 - p_0^2)^2(p_1^2 + p_0^2)}\,n \qquad (7)$$

As defined by equation (2), n^* is directly related to the square of the resolution, and the coefficient of n in the right-hand side of (7) corresponds to the slight loss of resolution which is incurred when operating a column for which C_l is negligible with a large drop in pressure This coefficient is unity when $p_1 - p_0$ is negligibly small if compared to p_0, and approaches $\frac{8}{9}$ monotonously as p_1 increases indefinitely

Hydrogen-bond Energies in the Crystalline State

MUCH interest and significance pertain to the energy of the hydrogen-bond molecular interaction present in many gaseous, liquid and solid systems[1] There are very few reliable estimates for its magnitude in the crystalline state, where its role is often a predominant feature of the lattice structure

Systematic measurements of the molar sublimation heats[2] which are very close to, if not identical with, the lattice energies per mole, allow more direct estimation of these hydrogen-bond energies than has been possible heretofore For the even-carbon members of the straight-chain monohydric alcohol series (from C_8 to C_{22}) all in the same isostructural polymorphic form, we find in kcal/mole

$$\Delta H_{\text{subl}} = 10\ 0 + 1\ 80\ n$$

where n is the 'carbon number' $H(CH_2)_n\,OH$ Putting $n = 0$ gives the total head-group contributions to the lattice energy, that is, the sum of the contribution due to the (OH) group and that arising from the difference between a terminal methyl (CH_3) and a chain methylene (CH_2) group The (CH_2) contribution is clearly 1 80 kcal/mole

In the heats of evaporation of the normal paraffins[3] the difference in the (CH_3) and (CH_2) contributions is 0 6 kcal/mole This difference can be expected to increase for the process of sublimation, and other considerations suggest that then ΔH_{subl} (CH_3) − ΔH_{subl} (CH_2) = 1 0 ± 0 2 kcal/mole This leads to ΔH_{subl} (OH) = 9 0 ± 0 2 kcal/mole

To deduce the energy increment due to the hydrogen-bonding condition of the (OH) group in these compounds, we still require an estimate of its lattice energy when not involved in hydrogen-bonding, but otherwise similarly placed to the (OH) group in the alcohols A definite minimum value for this 'free (OH) group' lattice energy has been deduced as 1 4 kcal/mole from the difference of the sublimation heats of 2,4 6-tri-*tert* butyl phenol and 2,4,6-tri-*tert* butyl benzene In this highly sterically hindered phenol the (OH) group is completely protected from hydrogen-bonding even in the crystalline state[4] A maximum of 2 8 kcal/mole is indicated for the same factor, for example, by ΔH_{subl} (CH_3), and a most probable value is 2 2 ± 0 4 kcal/mole Accordingly, the hydrogen-bond energy is (9 0 ± 0 2 − 2 2 ± 0 4), that is, 6 8 ± 0 6 kcal/mole

Again, for the straight-chain even-carbon monocarboxylic acids[5] and their methyl esters, we find, in kcal/mole

$$C_nH_{2n+1}COOH \quad \Delta H_{\text{subl}} = 14\ 2 + 1\ 50\ n$$

$$C_nH_{2n+1}COOCH_3 \quad \Delta H_{\text{subl}} = 7\ 7 + 1\ 95\ n$$

Both these series of compounds crystallize in a similar head-to-head layer lattice structure and so it is reasonable to suggest

$$\Delta H_{\text{subl}}\,(COOH) - \Delta H_{\text{subl}}\,(COOCH_3) = 14\ 2 - 7\ 7 = 6\ 5 \text{ kcal/mole}$$

In the absence of hydrogen-bonding in the acids, the difference (in the reverse direction) would arise from the replacement of (O—H) by (O—CH_3) This difference (essentially the lattice energy of the CH_3 group) is estimated to be 2 4 ± 0 4 kcal/mole, and this leads to 6 5 + 2 4 = 8 9 ± 0 4 kcal/mole for the carboxylic acid hydrogen-bond energy in the crystal

The energy increase relative to the alcohols (8 9 and 6 8 kcal/mole) is expected thus, in crystalline hexadecanol[6] the oxygen–oxygen distance (O–H O) is 2 71 ± 0 02 Å, in crystalline formic acid it is 2 58 Å and in dodecanoic acid[7] it is 2 56 Å Likewise, in the vapour of formic acid (HCOOH) the hydrogen-bond energy is 7 06 kcal/mole[8] that this becomes 8 9 kcal/mole in the crystalline state for the higher acids conforms to the shortening of the (O–H O) distance between the vapour state of the dimer and the crystal[9] by 0 15 Å A similar shortening with change of phase occurs for acetic acid

It may be mentioned that the difference[10] ΔH_{subl} (C_6H_5OH) − ΔH_{subl} (C_6H_6) is 16 1 − 10 5 = 5 6 kcal/mole correcting this for the 'free (OH) group' contribution by the figure already quoted for the difference between 2,4,6-tri-*tert* butyl phenol and 2,4,6-tri-*tert* butyl benzene (1 4) suggests 4 2 kcal/mole as the hydrogen-bond energy in crystalline phenol This is essentially the same as the value (4 3 kcal/mole) for hydrogen-bonded phenol in carbon tetrachloride

Further confirmation of the foregoing 'solid state' hydrogen-bond energies comes from measurements of the activation enthalpies ΔH^* involved in the kinetic process of their rupture, and so necessarily higher than their equilibrium ΔH values In crystalline *cyclo*pentanol and *cyclo*hexanol, dielectric studies[11] have given ΔH^* = 9 6 and 10 4 ± 0 4 kcal/mole for the bond in the alcohols, while ultrasonic data[12] give ΔH^* = 10 5 kcal/mole for the benzoic acid dimer

Quantitative Gas-liquid Chromatography of the Higher Fatty Acids

THE efficient separation of the higher fatty acids on polyester substrates[1–3], particularly with the addition of phosphoric acid, has been established for some time The quantitative aspects of such analyses have not, however, been stressed, since in addition to association affecting the response of thermal conductivity detectors, adsorption of various types in the column may occur[4]

The direct analysis of volatile fatty acids in dilute aqueous solutions on a quantitative basis has recently been shown to be possible through addition of formic acid vapour to the carrier gas, thus effectively suppressing adsorption of the weaker acids on the support and possibly in the substrate as well[5] This procedure can only be carried out with a flame ionization detector, since in this detector formic acid gives no response[6], but the presence of the formic acid does not affect the response characteristics of other carbon compounds

The extension of this quantitative technique to the higher fatty acids, using an efficient polyester substrate to give separations of the unsaturated acids equivalent to those obtained with their methyl esters, has been found to be practical

A flame ionization detector and simple device for adding formic acid vapour to the carrier gas were utilized as previously described[5], excepting that a pipping-pen integrator was used Although a low percentage of polyester would speed analyses[2,4], an available column of 20 per cent ethylene-glycol succinate (EGS) on 80–100 mesh 'Chromosorb *W*' was operated at 212° C with helium as the carrier gas at 20 lb /in ^{2} input for fatty acid analyses and at reduced flow (7 lb /in ^{2}) for certain ester analyses

Freshly prepared fatty acids from linseed oil, and their methyl esters prepared by the boron trifluoride procedure[7], were used in the present study Iodine values (Wijs) were determined by the Official Methods of the American

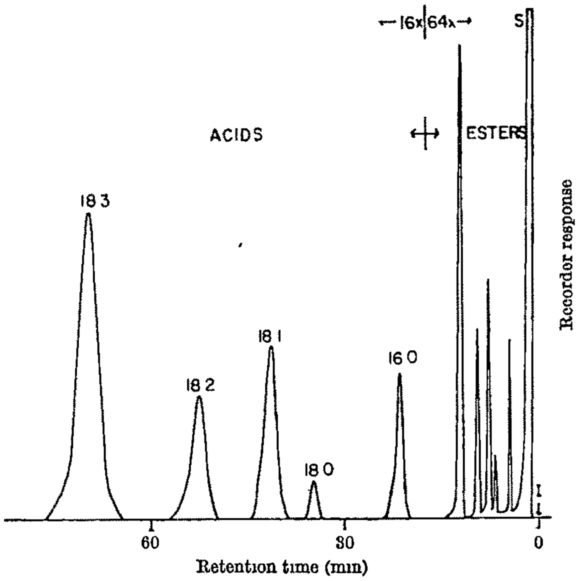

Fig 1 Simultaneous analysis of fatty acids from linseed oil and their methyl esters Column (6 ft × 1/8 in outer diam stainless steel, 20 per cent EGS on 80–100 mesh 'Chromosorb *W*') at 212° C utilizing helium carrier gas at 20 lb /in ² with added formic acid vapour Ester peaks are in the same order as acid peaks

Oil Chemists' Society All procedures were carried out in inert atmosphere. The esters and acids were injected in carbon disulphide solution (2 5 per cent w/v), samples of 0 005 ml being commonly used

With plain carrier gas repeated injections of the fatty acids failed to give any response on the recorder, indicating complete adsorption on the column When formic acid was added to the carrier gas reproducible analyses of acids were immediately obtained (Fig 1), although the previously adsorbed acids were not displaced by the formic acid in any obvious manner[5].

Since the acids and esters examined did not overlap (Fig 1, Table 1) it was feasible to carry out a simultaneous analysis of both materials For quantitative studies, however, the esters were also analysed (in the presence of formic acid vapour) at the reduced flow rate in order to give larger peaks The compositions were then calculated (Table 2) and from these were computed the iodine values, in reasonable agreement with the Wijs iodine values The ratios of the peak heights for the acids and esters when analysed simultaneously (Fig 1) were identical within ± 2 per cent, indicating that proportionality was maintained The individual counts for these ester peaks, although subject to high error owing to the few counts available, indicated on the average approximately equal weight response for the acids and esters Although the response should be slightly higher for the esters these observations all indicate that no significant loss of esters or acids occurred

Table 1 TYPICAL RETENTION TIMES* (MIN) FOR ANALYSES OF ACIDS AND ESTERS

Materials	Acids	Esters	
		With acids	Reduced flow
Palmitic	19 7	3 2	11 8
Stearic	32 6	5 5	19 6
Oleic	38 8	6 5	23 2
Linoleic	49 3	8 3	29 3
Linolenic	65 5	11 0	38 6

* Adjusted (from first solvent disturbance)

Table 2 PERCENTAGE OF COMPONENTS, AND IODINE VALUES (I V), AS INDICATED BY AREA RESPONSE FOR DIFFERENT ANALYSES OF ACIDS AND ESTERS

Materials	Acids		Esters	
Palmitic	8 7	7 4	8 7	8 6
Stearic	2 9	3 3	2 9	2 7
Oleic	17 5	17 4	16 3	17 7
Linoleic	16 8	16 5	15 7	16 0
Linolenic	54 8	55 4	56 4	55 1
I V (calc)	196	197	188	186
I V (Wijs)	199		188	

Theoretical plate numbers[8] as determined for linolenic acid and ester peaks in the mixed analysis were identical (about 2,400) within experimental error The other ester peaks were too narrow to permit accurate measurement The comparable ester peak at reduced flow gave a lesser value (about 900) and palmitic acid and ester peaks under the two different operating conditions gave proportionate values of approximately 2,000 and 700

Table 3 SEPARATIONS OBTAINED IN VARIOUS ANALYSES OF ACIDS AND ESTERS

Materials	Acids			Esters			
				With acids		Reduced flow	
Stearic/palmitic	1 65	1 66	1 64	1 71	1 70	1 70	1 70
Oleic/stearic	1 20	1 19	1 18	1 18	1 17	1 18	1 18
Linoleic/oleic (6/9)*	1 28	1 28	1 28	1 27	1 27	1 27	1 27
Linolenic/linoleic (3/6)*	1 32	1 34	1 32	1 33	1 33	1 32	1 32
Linolenic/oleic (3/9)*	1 68	1 70	1 69	1 69	1 68	1 67	1 67

* See ref 11

In examining the separations between various acids (Table 3), the slightly lower stearic/palmitic separation with the acids in contrast to the esters parallels the different vapour pressure ratios obtained for these materials at lower temperature[9] If the oleic/stearic separation is slightly less with the esters this may be due to lengthening of the chain, since the saturated and mono-unsaturated ester log plot lines[10] converge for this polyester in this temperature range as fatty acid chain length increases The systematic type II separation factors for the unsaturated acids and esters are, as predicted[11], virtually identical in all cases

Effect of Ultrasonic Radiation on the Crystallization of Polyethylene from Dilute Solution

THERE is much interest at present in the morphology of polymer single crystals grown from dilute solution, and, using polyethylene, Bassett and Keller[1] have recently attempted to systematize the relationship between crystal habit and preparative method In some of their experiments involving quenching, crystals of an unfamiliar type were sometimes observed. These took the form of necklaces very similar to those prepared by van der Heijde[2] in his examination of the crystallization of polyoxymethylene from dilute solution

In our experiments, 'Rigidex 50' polyethylene with $\overline{M}_w$ of $1\ 12 \times 10^6$ and a branching frequency of less than 1 per 1,000 was crystallized by pipetting 1 ml of a 0 5 per cent wt. solution in boiling *p*-xylene into a suitable volume of *p*-xylene thermostated at the appropriate temperature in an ultrasonic field Figs 1 and 2 show the general appearance under the electron microscope of the crystals from the resulting suspension The necklaces consist of roughly hexagonal platelets strung along a central filament In none of the preparations was the normal lozenge-shaped crystals totally absent, but they could have been formed as the suspensions cooled to room temperature in the absence of ultrasonic radiation The characteristic necklaces were produced over a range of

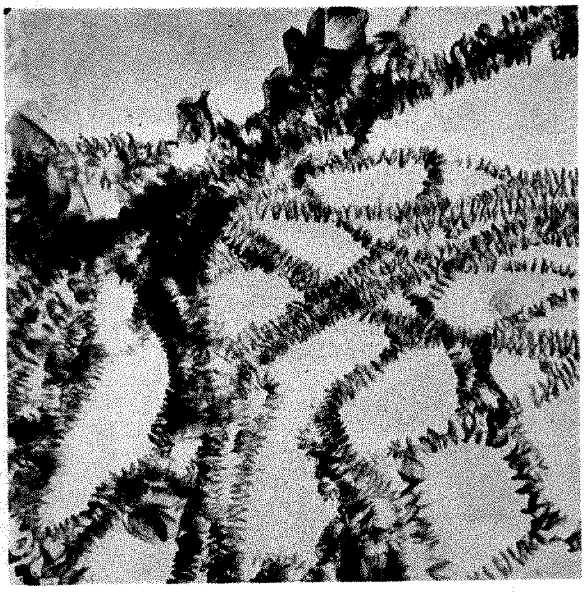

Fig. 1. Polyethylene. Gold–palladium shadowed at 30° C. (× 4,000)

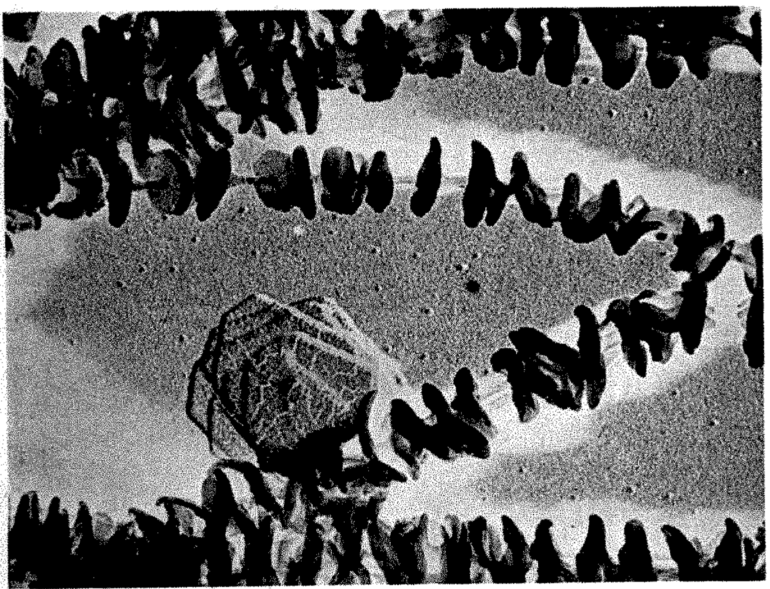

Fig. 2. Polyethylene. Gold–palladium shadowed at 30° C. (× 24,000)

conditions: (1) 0·05–0·1 per cent wt. solution, (2) 85–190 kc/s, (3) 82°–88° C, (4) 0·1–0·4 mW/cm^2. The experiments showed that 0·1 mW/cm^2 is the minimum power sufficient to produce the new crystals, but the other conditions do not necessarily represent limits. Niegisch[3] has produced similar forms at 75° C and 20 kc/s from dilute solutions of 'Marlex 50' polyethylene. The method of preparation we describe is evidently not unique, but polyethylene crystals of the new morphology are certainly typical of our technique which favours their production. Using a sample of Du Pont 'experimental polyoxymethylene' under similar conditions we were not able to produce necklaces though other anomalous crystals were detected.

At this stage it is not possible to say whether the effect of ultrasonic radiation on the morphology of polymer crystals is due primarily to a modification of the nucleation process or of the crystal growth stage, but the answer to this question is clearly relevant to the formulation of theories of crystallization mechanisms. We are at present using ultrasonic techniques as a means of investigating the crystallization process, and the observations reported here form part of a more general investigation.

We thank Mr. J. M. Bell for obtaining the electron photomicrographs and one of us (H. M. S.) thanks the U.S. National Science Foundation for a fellowship.

BIOPHYSICS

Molecular Lesions produced in Ribonuclease by Gamma-rays

Crystalline enzymes are very sensitive to inactivation by ionizing radiations. In general, one ionization within an enzyme molecule can result in the loss of catalytic activity[1-3]. Although these primary ionizations occur randomly within the molecule there is evidence from electron spin resonance investigations[4] that certain groups are preferentially damaged. There is, however, a scarcity of knowledge about the nature of the molecular lesions produced by ionizing radiation in biological macromolecules, and the forms of molecular damage responsible for the observed loss in enzyme activity are unknown.

Experiments are reported here which suggest that the direct action of ionizing radiation produces structural changes such as the breakage of certain disulphide bonds, and molecular conformity changes so that 'latent' tyrosyl groups become easily ionizable.

We have examined the radiosensitivity of ribonuclease (RNase) and the results have been reported elsewhere[3]. RNase is particularly well suited for studies on molecular damage, since a great deal is known about its structure. The amino-acid sequence of RNase has been determined[5], and it is known to possess four disulphide bridges[6]. The disulphide bridges are important in determining the conformation of the molecule, and their breakage results in loss of enzyme activity[7]. It appears, however, that not all the disulphide bridges are functionally important[8].

There is evidence that disulphide bridges may be broken in RNase[9] and in insulin[10] by ionizing radiation. We have assayed for the appearance of sulphydryl groups in samples of dry, purified, crystalline ribonuclease, irradiated in sealed tubes to a dose of 30 Mrads. This dose reduces the activity in air to 25 per cent.

The sulphydryl groups were titrated by the method of Boyer[11] using *para*hydroxymercuribenzoate (*p*OHMB) (Sigma Chemical Co., formerly catalogued as *para*chloromercuribenzoate (*p*CMB)). Increasing concentrations of ribonuclease were added to a constant concentration of *p*OHMB at *p*H 6·80 and the optical density at 255 mμ read at time zero. The optical density of irradiated RNase controls was also read at this time. The reaction vessels were closed and left for 12 h, at which time they were shaken and the optical density read. The results of an assay for RNase irradiated with 30 Mrads in air are shown in Fig. 1. The optical densities of the irradiated RNase were subtracted from those of the mixture to give a curve which represents the ultra-violet absorption due to the mercaptide formed from the combination of the *p*OHMB with sulphydryl groups. The equivalence point or 'knee' of the titration curve represents the point at which all the *p*OHMB is utilized. From this one can

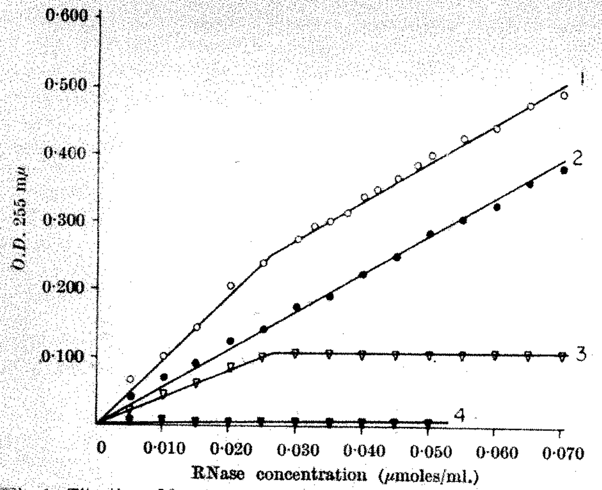

Fig. 1. Titration of free SH groups in RNase after a dose of 30 Megarads in air. The optical density (*O.D.*) is measured against that of a *p*OHMB blank. The knee of curve 3 represents equimolar concentrations of free SH groups and *p*OHMB

1, *p*OHMB (0·020 μmole/ml.) and irradiated RNase; 2, irradiated RNase; 3, 1 minus 2; 4, as in 3 for native RNase.

calculate the average number of radiation-produced, free SH groups per RNase molecule, and also the *G* value or yield of SH groups per 100 eV of γ-radiation absorbed. These are shown in Table 1 together with the yields for loss in enzyme activity under the same conditions. No free SH groups were detected in the native RNase. The appearance of SH groups following irradiation in air was also assayed at *p*H 4·5, and a slightly lower *G* value of 0·72 was obtained.

Table 1. Radiochemical Yields in RNase

Alteration observed	Units	Gaseous conditions during irradiation† O_2	N_2	NO
RNase molecules inactivated	/100 eV	3·00	1·53	0·93
Free SH* groups	/molecule	0·75	0·58	0·51
Disulphide bridges broken	/100 eV	0·95	0·67	0·63
Tyrosine groups unmasked	/100 eV	3·00	—	—

* Dose, 30 Megarads.
† Initial rate of breakage.

An experiment has been performed which shows that the total number of disulphide groups which are available for assay after chemical reduction remains unchanged following the irradiation. This suggests that the sulphur–sulphur bonds of the cystine groups (disulphide bridges) are broken by irradiation of RNase in the dry state, and it seems unlikely that C—S bonds of either cystine or methionine groups are broken.

The average titre of SH groups produced increased with dose, and appeared to approach an average of two per molecule. This is compatible with the assumption that only one disulphide bond per average molecule may be broken by the radiation.

RNase has six tyrosyl (phenolic) groups, three of which ionize easily with a *pK* of 10 and three of which are hidden within the molecule and are not readily ionized[12]. These ionized tyrosyl groups absorb strongly in the region of 295 mμ, and one can titrate them spectrophotometrically. Changes in the titration curve of these tyrosyl groups should indicate structural changes within the molecule.

Ionizing radiation caused a hyperchromic effect in the ultra-violet absorption curve of ribonuclease. Elevation of the hydrogen ion concentration also produced a hyperchromic effect (Fig. 2). The hyperchromic effect due to *p*H elevation was more marked in the region 290 mμ for irradiated ribonuclease than for the native enzyme, which suggested that tyrosyl group ionization was being changed. Spectrophotometric titrations at 295 mμ were carried out for native and irradiated ribonuclease after the method of Tanford[12]. The results are shown in Fig. 3. The increase in the extinction coefficient of native ribonuclease takes place in two equal steps, and Tanford interprets this as representing the ionization of three exposed tyrosyl groups followed, at higher *p*H, by the ionization of three tyrosyl groups which are hidden within the molecule. The ionization curve of irradiated ribonuclease is different, in that the first step is higher. This indicates that some latent tyrosyl groups have been unmasked so that they ionize at lower hydrogen ion concentrations. There is a striking similarity between the titration curve for irradiated RNase and that reported for RNase[13] in which hydrogen bonds were broken by guanidine hydrochloride.

At present, it is not possible to make a direct correlation between disulphide bond breakage and loss in enzyme activity although disulphide bonds might be important to enzyme activity[7]. The yield for sulphydryl group appearance is generally considerably lower than that for loss in enzymatic activity, so disulphide breakage may at the most be responsible for a fraction of the total

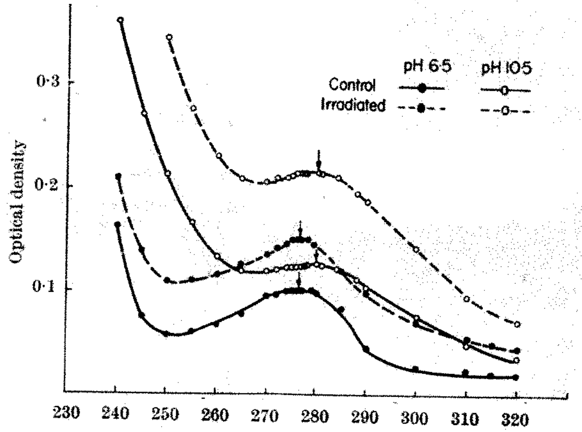

Fig. 2. Ultra-violet absorption spectra of irradiated and native RNase. Note the hyperchromic effect in the irradiated samples (dashed lines) after a dose of 30 Megarads in air, and the enhanced effect at higher *p*H. Enzyme concentration, 10^{-5} M

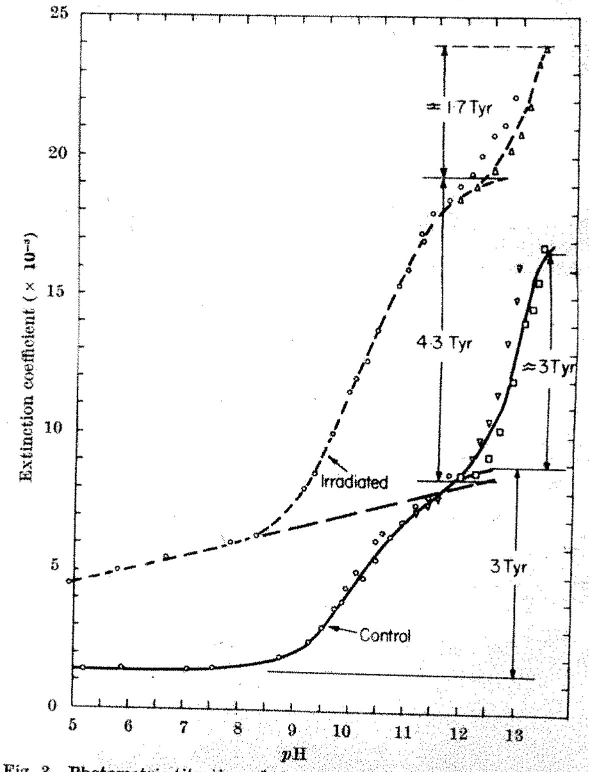

Fig. 3. Photometric titration of phenol (tyrosine) groups in native and irradiated RNase. After 30 Megarads, the number of unmasked tyrosine groups have increased from 3 to 4·3

Groups in RNase 295 mμ; absorbed dose, 30 Mrads damage. The possible exception to this is for irradiation in nitric oxide where both yields are of similar magnitude

It is possible that the appearance of the unmasked tyrosyl groups accompanies the breakage disulphide bridges, that is, the three tyrosyl groups are unmasked as a result of the breakage of a single disulphide bridge Tanford has suggested that the tyrosyl groups themselves might be involved in hydrogen bonding and that such bonds could be important in maintaining the tertiary structure of the molecule

An Alpha-globulin Allotype in the Mouse (MuB1)

Polymorphism, detected by antibody from individuals of the same species (allotypy), has so far been observed only in the γ- (ref 1) and β-globulins (ref 2) In man, a class of α-globulin *Gc*1 and *Gc*2 is subject to genetic variations and has been revealed by antibodies of heterologous origin[3] Polymorphism of other α-globulins, the haptoglobins in several mammalian[1] species and recently the trypsin inhibitors in man[4,5] have been detected by other means So far, the polymorphism of serum proteins has been most thoroughly examined in man and rabbit In the mouse the genetic variation of the transferrins[6] and of an allelic pair of γ-globulins (*MuA*1 and *MuA*2) (refs 7–10) have been examined We wish to report here a new allotypic specificity among the α-globulins of the mouse

Antibody was induced in *DBA/2J* and *A/HeJ* mice immunized with the serum of *DBA/1J* and *C57L/J* mice, respectively Mice were given subcutaneously, or into the foot pad, six injections of serum incorporated in complete Freund's adjuvant On the fifth day after the last injection, the animals were bled from the tail, and the sera from the two groups of animals (*DBA/2J* and *A/HeJ*) were pooled separately Both pools of sera reacted in an identical manner, giving one zone of precipitation in double diffusion with the serum of *BALB/cJ*, *CBA/J*, *C57BL/10J*, *C57Br/cdJ*, *C58/J*, *C57L/J*, *129/J*, *SJL/J*, *C3H/HeJ* and *DBA/1J* mice The specificity was absent in mice of the *A/HeJ*, *A/J*, *AKR/J*, *RF/J*, *SWR/J* and *DBA/2J* strains A number of hybrid strains were also tested *AKR/J* × *DBA/2J*, *C57BL/6J* × *A/J*, *C57BL/6J* × *DBA/2J*, *BALB/cJ* × *A/J*, *C57L/J* × *A/HeJ*, *C3H/HeJ* × *DBA/2J*, *C3H/HeN* × *C57BL/6J*, and only the hybrid *AKR/J* × *DBA/2J* was found to lack the allotypic specificity under investigation In short, all hybrids having in their ancestry one or two of the strains containing the allotypic specificity also possessed the allotypic specificity in their serum

In all cases, 3 or more males and 3 or more females were tested for the presence of the allotypic specificity and in all cases the distribution of the allotypic specificity in males and females was identical

In addition to inbred mice examined, forty 'Swiss' mice, from the Connaught Laboratories and from our own colony, were found to possess the allotypic specificity under investigation Five serum samples of woodland deer mouse (*Peromyscus maniculatus gracilis*) were also examined and found to give a reaction of partial identity with the allotypic specificity of strains such as *DBA/1J* These samples did not produce any detectable reaction with a previously described *MuA*2 antiserum.

The antibody from *DBA/2J* and *A/HeJ* mice was shown by immunoelectrophoresis to react with an α-globulin, the mobility of the α-globulin was located by comparison with that of some well-defined human proteins (Fig 1) Since it has been previously proposed to call the γ-globulin allotypes *MuA*1, *MuA*2, MuA_n[8,9], we now propose to call the α-globulin family of allotypic specificities *MuB* and the specificity here described *MuB*1

BIOCHEMISTRY

X-Irradiation of Deoxyribonucleic Acid

One of the biochemical effects of X-irradiation is the inhibition of synthesis of DNA Although Okada and Hempelmann[1] showed that, after ionizing radiation, there is an inhibition of the activities of enzymes essential for DNA synthesis, the experiments of Bollum *et al*[2] indicate that regenerating rat liver can still synthesize thymidylic kinase and DNA polymerase in tissues where DNA synthesis has been suppressed by X-irradiation Walwick and Main[3] reported that the enzymes catalysing synthesis of DNA are unaffected by X-radiation at dose-levels (100–5 000 rads) ordinarily encountered in radiation biology. Stacey[4] found that the ability of X-irradiated DNA to 'prime' the action of polymerase is reduced, but only by relatively high doses

This communication describes another feature of the effect of X-irradiation of DNA, namely, a loss of ability of Ehrlich ascites carcinoma cells to take up irradiated DNA and an increased susceptibility of DNA to DNase after X-irradiation

DNA labelled with carbon-14 used in these experiments was prepared as follows Ehrlich ascites carcinoma cells from 8 mice, 5 days after inoculation, were collected by centrifugation and washed with saline free from erythrocytes, yielding about 7 ml of packed cells The ascites cells were incubated in 120 ml of isotonic Krebs–Ringer medium containing 2 4 m moles of *tris* buffer, *p*H 7 4, and 8 μc of thymidine-2-^{14}C (66 4 μg) for 3 h at 37° shaken aerobically in a Research Specialties Co water bath shaker After incubation, the ascites cells were collected by centrifugation and washed with saline DNA of the ascites cells was isolated by the method of Marmur[5] up to RNase treatment and then by the method of Kay, Simmons and Dounce[6] onwards from step 8 About 3 mg of DNA were obtained from 1 ml of packed ascites cells, yielding 26,000–30,000 c p m /mg DNA Heated DNA samples were prepared by keeping a solution of ^{14}C-DNA (0 3 mg per ml 0 01 M sodium chloride) at 100° for 10 min and then cooling it in an ice bath. X-irradiated DNA samples were prepared by irradiating (500 rads for 5 min) a solution of ^{14}C-DNA (0 3 mg per ml 0 01 M sodium chloride) in a Petri dish 1 ml (0 3 mg) of X-irradiated ^{14}C-DNA was used for each experiment

For the examination of cellular uptake of ^{14}C-DNA, 0 1 ml of Ehrlich ascites cells was incubated in 3 0 ml of isotonic Krebs–Ringer medium containing 60 μmoles of phosphate buffer, *p*H 7 4, and 0 3 mg of ^{14}C-DNA in an Erlenmeyer flask shaken aerobically in a water bath shaker for 60 min at 37° After incubation the contents of the flask were centrifuged, washed twice with 10 ml each of saline and once with 95 per cent ethanol, ethanol/ether (3 1) and then ether The residues were then suspended in a small amount of chloroform/ether (4 1), plated on aluminium planchets, and their radioactivities were counted The control counts of radioactivity, in which ^{14}C-DNA and ascites cells in the same medium were mixed in ice and washed immediately as already described, were subtracted from the counts found in experiments in which the incubation was carried out for 60 min at 37°

Table 1 CELLULAR UPTAKE OF ^{14}C-DNA BY EHRLICH ASCITES CARCINOMA CELLS

^{14}C-DNA preparation	Uptake (counts/2 min)
Native DNA	290
Heated DNA	139
X-irradiated DNA	0
Native DNA + DNase	0

As shown in Table 1 when ^{14}C-DNA is X-irradiated with 500 rads for 5 min no uptake is observed When heated DNA is used instead of native DNA the uptake is reduced The uptake is also reduced after treatment of DNA with pancreatic DNase (8 μg/ml) However, when DNA is radiated in the presence of 1 mM cysteine, the activity taken up by ascites cells is almost undiminished In the present experiments the localization of ^{14}C-DNA in the ascites cells was not studied This is now under investigation

The increased susceptibility of DNA to DNase activity after X-irradiation, or heating, was shown in the following manner 0 3 mg of ^{14}C-DNA was incubated in 2 0 ml of medium containing 80 μmoles of *tris* buffer, *p*H 7 4, 10 μmoles of magnesium chloride and 0 5 ml of 1 5 ascites homogenate in water for 60 min at 37°. After incubation, 1 ml of 30 per cent trichloroacetic acid (TCA) was added and the contents were centrifuged The clear supernatant was extracted three times with 6 ml each of ether to remove TCA Aliquots of the aqueous phase were plated and their radioactivities counted As shown in Table 2, DNase in ascites cells hydrolyses heated and X-irradiated DNA faster than native DNA The results indicate that not only is there a loss of ability of Ehrlich ascites carcinoma cells to take up irradiated DNA but also that a change occurs in DNA after X-irradiation whereby its susceptibility to DNase activity is increased

Table 2. DNASE ACTIVITY OF ASCITES CELLS WITH DIFFERENT SAMPLES OF DNA

^{14}C-DNA used as substrate	DNase activity total counts in TCA-soluble fraction
Native DNA	1,572
Heated DNA	3,060
X-irradiated DNA	2,310

Participation of Purine and Pyrimidine Nucleotide Sequences in the Molecule of Calf Thymus Deoxyribonucleic Acid

A METHOD was recently developed in this laboratory by which it was possible to degrade DNA chemically to sequences of purine nucleotides[1,2] During this procedure the DNA is first freed of pyrimidines by heating with anhydrous hydrazine and then degraded in alkali, the fragments formed are separated by chromatography on DEAE cellulose in a lithium chloride gradient Accurate quantitative analysis revealed that most purine nucleotides occur in calf-thymus DNA in sequences of two or more purine nucleotides[3] The results make it possible to calculate the frequency of occurrence of the individual purine nucleotide sequences in the DNA molecule (Table 1)

The frequency of occurrence of the individual sequences corresponds to the probability of occurrence of analogous sequences in a model system arranged as follows A certain number (n) of nucleotides of the same type (marked a) is arranged in all possible ways so that the number of nucleotides in every arrangement would be equal to n and so that no arrangement would be repeated, the sequence of the individual units being of no concern Thus, for example, for $n = 5$ a total of 7 arrangements are possible, namely, $aaaaa$, $aaaa+a$, $aaa+a+a$, $aaa+aa$,

Table 1 DISTRIBUTION OF PURINE AND PYRIMIDINE* NUCLEOTIDES IN CALF-THYMUS DNA

Sequence	Purine nucleotide clusters: % of total purine nucleotides in this type of sequence	Purine nucleotide clusters: Frequency of occurrence of the cluster (%)	Pyrimidine nucleotide clusters: % of total pyrimidine nucleotides in this type of sequence	Pyrimidine nucleotide clusters: Frequency of occurrence of the cluster (%)
$p\,N\,p$	17 3	44 0	17 9	44 1
$p\,(N\,p)_2$	15 8	20 0	17 6	21 6
$p\,(N\,p)_3$	15 4	12 9	15 5	12 7
$p\,(N\,p)_4$	12 8	8 1	13 6	8 3
$p\,(N\,p)_5$	10 9	5 6	9 9	4 9
Longer sequences†	27 8	9 4	25 5	8 4

* The values referring to the pyrimidine nucleotide clusters are calculated from data of Spencer and Chargaff (ref 4)

† The average chain length of this fraction corresponds to 7 6 nucleotides

Table 2 DISTRIBUTION OF NUCLEOTIDES IN THE MODEL SYSTEM FOR DIFFERENT MEANINGS OF n

Sequence	% of total nucleotides in this type of sequence $n=12$	$n=13$	$n=14$	Frequency of occurrence % of this type of sequence $n=12$	$n=13$	$n=14$
a	21 1	20 6	19 7	49 0	48 9	47 7
aa	18 0	17 0	16 9	20 7	20 1	20 6
aaa	14 6	14 4	13 8	11 2	11 3	11 2
aaaa	12 1	11 6	11 6	7 0	6 8	7 1
aaaaa	9 2	9 6	9 3	4 3	4 5	4 5
Longer sequences	25 0	26 7	28 6	7 8	8 3	9 0

$aa+aa+a$, $aa+a+a+a$, $a+a+a+a+a$ (since the sequence of units makes no difference the following arrangements are taken as equal $aaa+a+a$, $a+aaa+a$, $a+a+aaa$) The whole set is composed of 20 sequences of five types, the sequence *aaaaa* occurring once, *aaaa* also once, *aaa* twice, *aa* four times and *a* twelve times. The probability of occurrence of the individual sequences is determined by the ratio of participation of the sequence type investigated to the total number of all sequences of the set investigated, for example, the probability of occurrence of sequence *aa* is 4 20 = 0 20, that is, 20 per cent The probability of occurrence of the individual sequences depends considerably on the number of nucleotides (n) which are taken into consideration Thus for $n=2$ the probability of occurrence of sequence *aa* is 33 3 per cent, while for $n=20$ only 19 8 per cent, etc

The frequency of occurrence of the individual sequences of purine nucleotides from calf-thymus DNA corresponds to the probability of occurrence of analogous sequences of a model system derived in the foregoing way for $n=13$ to $n=14$ (Table 2)

The same law holds for the distribution of pyrimidine nucleotide sequences in the molecule of this DNA if the data published by Spencer and Chargaff[4] on the participation of nucleotides in the individual sequences of pyrimidine nucleotides are expressed with respect to the frequency of occurrence of the given sequences quite analogous results are obtained (Table 1) Even here the frequency of occurrence of the individual sequences corresponds to the probability of occurrence of these sequences in the foregoing model system for $n = 12$ to $n = 13$

This regularity of occurrence frequency of the individual sequences makes it possible to assume that the longest monothematic sequences of purine as well as pyrimidine nucleotides occurring in calf-thymus DNA are formed by 13 nucleotides According to the laws of probability, a molecule containing a single purine 13-nucleotide must also contain another 555 sequences similarly as the corresponding model system for $n=13$ If now the purine nucleotides in all these 556 sequences are added the total number of nucleotides is 1,313 The numbers of pyrimidine sequences and nucleotides are the same, the molecule of calf-thymus DNA contains thus (for $n=13$) a total of 2,626 nucleotides in the polynucleotide chain which corresponds to a molecular weight of $8\ 1 \times 10^5$ The intact molecule of calf-thymus DNA formed by two basic polynucleotide chains arranged in the double spiral should thus have a molecular weight in the vicinity of $1\ 6 \times 10^6$ The number n is thus a function of the molecular weight of the fundamental polynucleotide chain

The equal participation of the individual purine and pyrimidine sequences thus confirms the correctness of the Watson–Crick model of the double spiral of DNA (ref 5) against a sequence of purine nucleotides there must always be an analogous one of pyrimidine nucleotides

Effect of Injection on Nicotinamide Adenine Dinucleotide-levels

DURING an investigation of the possible *in vivo* effect of redox dyes on the distribution of oxidized and reduced nicotinamide adenine dinucleotides (NAD+ and NADH), it was noted that the ratios and/or levels of these co-enzymes can be altered by injection of distilled water alone

To standardize experimental conditions, only male rats, 11–12 weeks old and bearing 6-day Walker tumour implants, were used, and injection and killing (by cervical dislocation) of all the animals were carried out at the same time of day. The rats were divided into 3 groups Group I, 12 rats which had not received an injection , Group II, 5 rats injected intraperitoneally with 1 ml distilled water per 100 g body-weight , Group III, 5 rats injected intraperitoneally with 1 ml per 100 g body-weight of an aqueous solution of leuco base of indophenol blue (1 25 mg/ml).

Groups II and III were killed 0 5 h after injection.

The liver, kidney, spleen, tumour and left hind muscle were removed as quickly as possible, cut into small pieces, and frozen in liquid nitrogen The samples were immediately weighed (without being allowed to thaw), and were then homogenized and analysed according to the method of Caiger *et al* [1]

The results are presented graphically in Figs 1 and 2 Marked differences in the levels of nicotinamide adenine dinucleotides were observed only in the spleen, kidney and liver of Groups II and III as compared with Group I Two striking effects are apparent First, that under the conditions specified the leuco base of indophenol blue does not influence absolute or relative concentrations of NAD+ and NADH, since water gave virtually identical results. Second, the NADH concentration is distinctly less in both water and dye injected animals, resulting in an almost two-fold increase in the NAD+/NADH ratio Since no

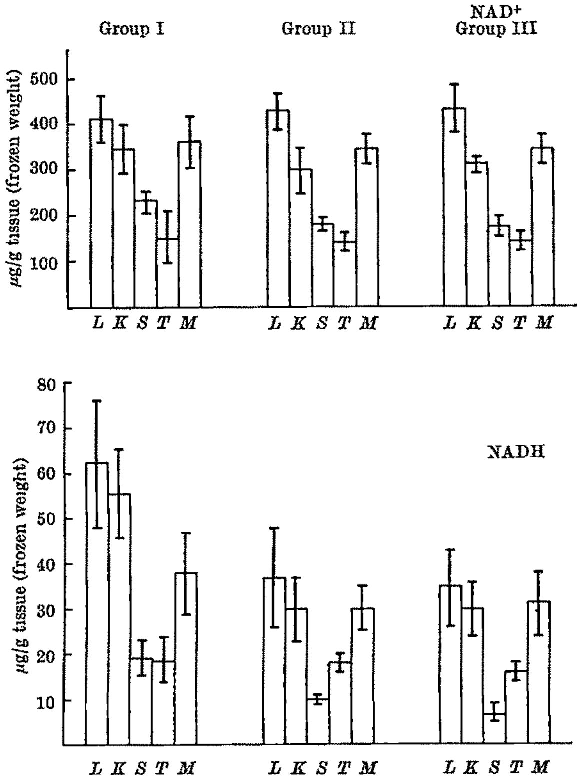

Fig 1 Distribution of NAD+ and NADH in the various tissues of the three groups of rats The standard deviations are indicated Group I, no injection , Group II, water injection, Group III, dye injection Tissues examined were liver (*L*), kidney (*K*), spleen (*S*), tumour (*T*), muscle (*M*)

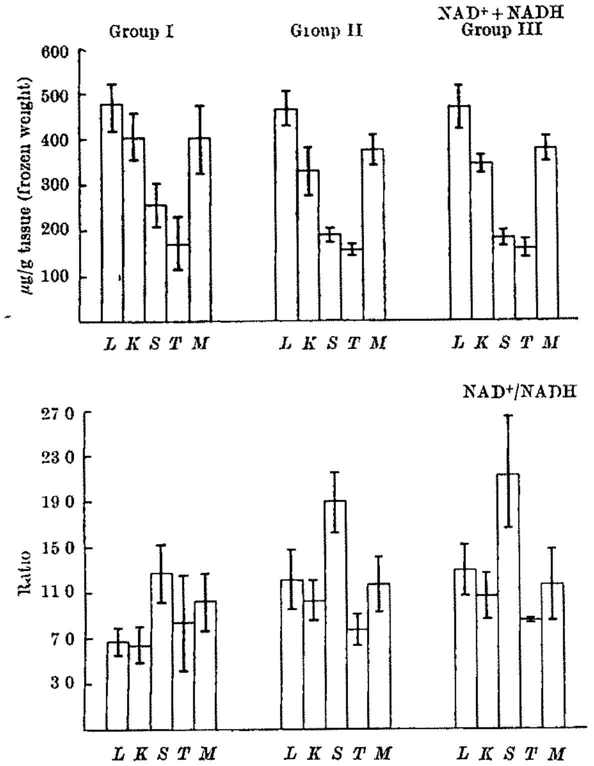

Fig. 2. Distribution of total coenzyme and NAD+/NADH ratio in the various tissues of the three groups of rats. The standard deviations are indicated. For details see Fig. 1

rise in the NAD+ level was observed (perhaps even a slight loss is indicated), it seems probable that a destruction or non-formation of reduced co-enzyme has occurred.

These findings suggest that injection *per se* can have a marked effect on the ratio and levels of nicotinamide adenine dinucleotides. Other workers have reported on the effect of stress on biological components, for example, non-protein sulphydryl groups[2,3] and blood sugar[4,5]. This investigation also confirms reports by other workers that NAD+ levels are low in tumours[6-8].

The question arises whether this stress affects NAD+ and NADH similarly in both normal and tumour-bearing animals. Extensive investigation on this problem is required. If qualitatively different reactions are obtained between normal and tumour-bearing animals this might yield further insight into the process of malignancy.

This research was carried out as a preliminary investigation to a co-operative study of the problem of biological and biochemical characterization of human cancers. We thank Miss P. Briggs for her assistance and Dr. D. A. Gilbert for his advice.

Acid Mucopolysaccharide Content of Dermal Connective Tissue of Normal and Hypophysectomized Rats

PREVIOUS investigations conducted in our laboratory have shown a parallel relationship between the *in vitro* oxidative-reductive depolymerization of hyaluronic acid and the *in vivo* 'permeability' changes of dermal connective tissue[1-5]. These results suggest that hyaluronic acid may play a part in the permeability of dermal connective tissue. Our investigations concerning substances which act as activators and others which act as inhibitors of connective tissue 'permeability' also have shown that a different effect is obtained using hypophysectomized and adrenalectomized rats as compared with normal rats[6]. This result led us to investigate the content of mucopolysaccharides in the dermal connective tissue of normal and hypophysectomized rats in order to establish whether the amounts of these substances are affected by the pituitary function.

Experiments were performed on rats 3–5 months old, *CFE* strain of both sexes. The hypophysectomized animals were purchased from N. and J. Supply, Inc., New City, Rockland County, New York. The animals were fed 'Wayne Lab Blox' (mice and rats) diet[7]. The animals were hypophysectomized about 2 weeks prior to use. One group of female rats was used 2 months after being hypophysectomized in order to establish whether the time after hypophysectomy would affect the mucopolysaccharide content. These animals maintained a stationary weight throughout this period.

Both control and hypophysectomized rats were killed by bleeding them from the aorta. The skin of the dorsal and lumbo-dorsal region was shaved and taken for analysis. It was ground into powder, defatted in a Soxhlet extractor using acetone and dried at 80° C in a drying oven. The mucopolysaccharides were extracted and isolated following a slight modification of the technique described by Schiller *et al.*[8]. The mucopolysaccharides were finally precipitated with cetylpyridinium chloride and the precipitate was washed with 0.03 M sodium chloride. From the precipitate, hyaluronic acid, chondroitin sulphate and heparin were extracted successively with 0.4, 1.2 and 2.1 M sodium chloride. The mucopolysaccharide content of different fractions was determined by the carbazole method of Dische[9] which is based on the uronic acid content. Glucurone was used as standard. The results are shown in Tables 1 and 2. The values are expressed as μmg of glucurone equivalent per gram of dry skin, they do not correspond, therefore, to actual but relative values of mucopolysaccharide content. The results obtained on normal animals (Table 1) are closely similar to those reported by Schiller and Dorfman[10] for normal rats of the same age. Moreover, the present results show no difference in the concentration of mucopolysaccharides in male and female rats.

In comparing the results obtained with normal and hypophysectomized animals (Tables 1 and 2), no difference is apparent between the various fractions and total mucopolysaccharide content for both groups.

Schiller and Dorfman[11] reported data on the turnover of hyaluronic acid and chondroitin sulphate in normal and hypophysectomized rats. This was done by the administration of both acetate-1-^{14}C and $Na_2{}^{35}SO_4$. The authors found the half-life times of 2.9 and 4.8 days, respectively, for hyaluronic acid and chondroitin sulphate in normal rats and 5.1 and 11.7 days, respectively, for hyaluronic acid and chondroitin sulphate in hypophysectomized rats.

Schiller also reported in another study[12] that hypophysectomy resulted in a progressive increase of hyaluronic acid, while the concentration of chondroitin sulphate steadily decreased.

Our results do not confirm this last finding. The discrepancy can be, however, due to the difference in the age of animals used in both experiments. Schiller used 4-week-old rats, whereas the animals in our experiments

Values for pooled sample from 4 female rats, 2 months after hypophysectomy:	840	71	23	6

were about 3 to 5 months of age. Schiller and Dorfman[10] found the concentration of hyaluronic acid and chondroitin sulphate in the skin of 44-day-old rats to be much greater than that of mature rats.

The results of the present work suggest that the *in vivo* 'permeability' changes of dermal connective tissue which follow the ablation of the pituitary may not be a result of a change in the concentration of mucopolysaccharides, but could possibly result from a decrease in the degree of polymerization of the hyaluronic acid or other mucopolysaccharides as suggested earlier[6].

In conclusion, the present findings show that hypophysectomy does not affect the mucopolysaccharide content of skin, at least not in adult rats. The concentrations of the different mucopolysaccharides are not affected even 2 months after the hypophysectomy.

Effect of Propanol–Water Mixtures on the Reactivity of Wool Cystine

THIS communication shows that the concept of hydrophobic bonds in interactions of soluble proteins[1] can also be applied to water-insoluble fibrous proteins. It has been observed[2,3] that lanthionine formation in wool at 65° C with sodium hydrogen carbonate or borate is much faster in mixed solvents than in aqueous solutions. This effect was not explained by the authors. It was also found by Atkinson, Filson and Speakman[4,5] that it is more difficult to extend wool fibres in water alone than in saturated aqueous butanol. Now there is evidence that addition of organic solvents will tend to overcome the resistance of the hydrophobic interior of proteins to penetration by the aqueous solvent and thus may increase the reactivity of protein groups located in hydrophobic regions.

New experiments (Fig. 1) on the relationship of propanol concentration to the wool cystine degradation by 0·1 normal sodium carbonate at 45° C gave a maximum cystine reactivity in 60 per cent (v/v) aqueous propanol. In Fig. 1 the results given in ref. 3 for the same solvent are included to show the close similarity of the solvent effect.

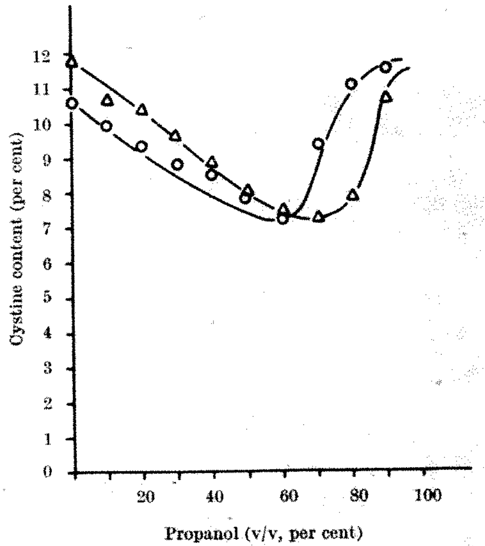

Fig. 1. Change in the cystine content in merino wool in 0·1 normal sodium carbonate: 45° C, 2 h (○) and in 0·5 molar borate solution: 65° C, 4 h (△) as a function of the concentration of propanol

The results suggest that the increased reactivity of wool cystine bonds in 10–80 per cent (v/v) aqueous propanol is best described as the consequence of a non-specific interaction of the solvent with the wool protein, resulting in the weakening of the hydrophobic interactions and the consequent exposure of wool cystine groups to the action of alkali.

Note added in proof. J. A. MacLaren (*Austral. J. Chem.*, **15**, 824; 1962) also regards wool as a protein linked by hydrophobic as well as hydrophilic interactions and found the extent of reduction of wool by thiols in aqueous alcohols increased.

PHYSIOLOGY

Effects of Calcium Ions on Prolonged Action Potentials and Hyperpolarizing Responses

The membrane of excitable tissue is capable of maintaining two different states, namely, either the resting state or the acting state. These two states are defined in terms of the membrane permeability to sodium and potassium ions; P_{Na}/P_K is small in the resting state whereas it is large in the acting state. Our recent experimental results suggest that the membrane potential may be dependent on the state of the membrane calcium which is probably located in a layer of lipoproteins[1]. In other words, the resting state of the membrane will be the condition in which calcium ions are associated with the membrane, and the acting state, the condition in which these ions are dissociated from the membrane. This concept is supported by the recent findings that P_{Na}/P_K is markedly increased when the membrane calcium is removed[2]. It is expected that the dissociation of the membrane calcium will be impeded when the concentration of calcium in the external solution is high, and accelerated when it is low or nullified. The membrane, therefore, will tend to stay in the resting state or acting state depending on the external concentration of calcium. Indeed, the excitable membrane is depolarized and often initiates action potentials spontaneously when the concentration of calcium in the external solution is reduced. Furthermore, it has recently been found that the action potential of frog's pinal ganglion cells is markedly prolonged in Ringer's solution containing no calcium ions[3].

It is known that the action potential of various excitable tissues is prolonged under certain experimental conditions, and also that the depolarized membrane produces hyperpolarizing responses when anodal currents are applied. It is considered that these potentials are produced by the transition of the state of the membrane between two physicochemically stable states[4]. If the two stable states of the membrane actually correspond to the resting and acting states, it will be expected that the increase in the external concentration of calcium will prevent the prolongation of the action potential or prolong the hyperpolarizing response of the depolarized membrane.

Toad's (*Bufo vulgaris formosus*) spinal ganglion with the dorsal root and sciatic nerve attached was used. The changes in the membrane potentials were recorded continuously with an intracellular microelectrode during which time the external perfusing solution was changed from Ringer's solution to the control solution. The time needed for changing the perfusion solution was one-tenth of a second. At the end of each experiment, the solution was changed back to Ringer's solution to ascertain reversibility. The technique of using a single intracellular microelectrode for both recording and stimulating was essentially similar to that described elsewhere[5].

It is known that the action potential of ganglion cells is prolonged when tetraethyl ammonium (TEA) is partially or totally substituted for sodium in the external solution[5]. The superimposed responses in record *A* (Fig. 1) were taken approximately 3 min after the external solution was changed from Ringer's to the control solution (TEA-chloride 87 mM, potassium chloride 2·0 mM, calcium chloride 1·8 mM, potassium bicarbonate 0·5 mM and sucrose 55 mM). Immediately after the responses were recorded, the control solution was changed to a calcium-rich TEA solution (TEA-chloride 87 mM, potassium chloride 2·0 mM, potassium bicarbonate 0·5 mM and calcium chloride 20 mM), whereupon the prolonged potential was rapidly shortened. As seen in record *B*, 5 responses were superimposed at intervals of 2 sec.

As Tasaki[6] has demonstrated, barium ions markedly prolong the action potentials of cells. Record *C* shows such a potential of a cell during perfusion with barium solution (barium chloride 58 mM, potassium chloride 2·0 mM, calcium chloride 1·8 mM, potassium bicarbonate 0·5 mM and sucrose 55 mM). The response of the same cell shortened as soon as the barium solution was changed to a calcium-rich barium solution (barium chloride 58 mM, potassium chloride 2·0 mM, potassium bicarbonate 0·5 mM and calcium chloride 20 mM) as shown in record *D* in which 6 responses were superimposed every 2 seconds.

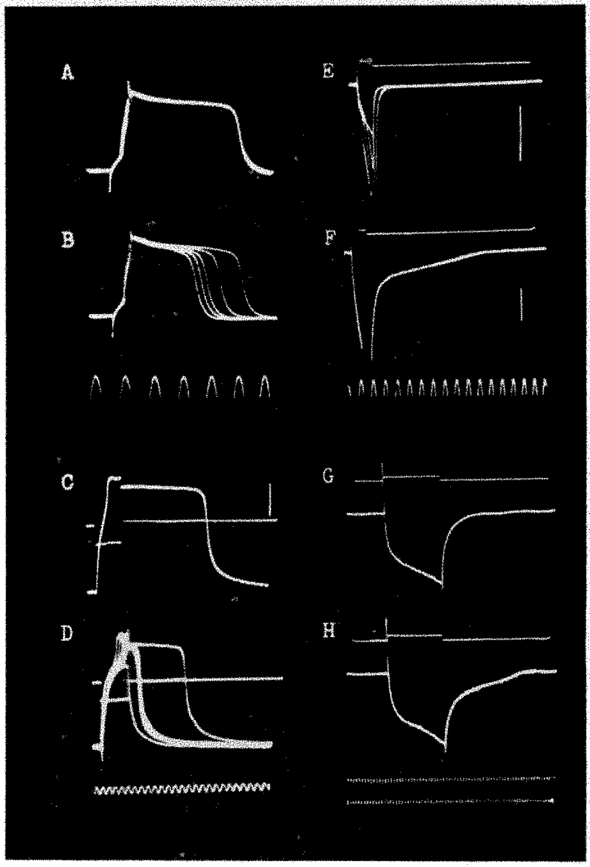

Fig. 1. Time marks: 60 cycles for all records except record *H* (1,000 cycles). Voltage calibration: the vertical bar in record *E* represents 50 mV calibration which is applicable to all records. Current calibration: the vertical bar in record *C* represents a calibration of 4×10^{-9} amp for records *C* and *D*, and that in record *F* represents a calibration of 5×10^{-8} amp for records *E*, *F*, *G* and *H*

The depolarized cell membrane in potassium-rich Ringer's solution is capable of producing a hyperpolarizing response during application of anodal currents[3]. The hyperpolarizing responses in a sodium-deficient potassium-rich solution, as a rule, abruptly returned to the initial depolarized potential level after the break of the anodal currents (duration: 20 msec), but in some cases showed a small plateau (step). Anelectrotonic potentials, induced by applying anodal currents ranging from 3×10^{-9} to 1×10^{-8} amp, of a cell perfused for 5 min with a sodium-deficient potassium-rich solution (potassium chloride 40 mM, sodium chloride 48·5 mM, calcium chloride 1·8 mM, sodium bicarbonate 0·5 mM and sucrose 55 mM) are shown in record *E*. In this case no plateau (step) formation could be observed following the break of the applied currents. However, when a calcium-rich potassium-rich solution (potassium chloride 40 mM, sodium chloride 48·5 mM, calcium chloride 20 mM and sodium bicarbonate 0·5 mM) was substituted for the sodium-deficient potassium-rich solution, a plateau soon appeared lasting for about 150 msec after the break of the applied currents (record *F*).

A similar effect of calcium ions could be observed when chlorine ions were completely replaced with glutamate ions (records *G* and *H*). In this experiment, the preparation was first perfused with a potassium-rich chlorine-free solution (sodium glutamate 58 5 mM, potassium glutamate 30 mM, sucrose 55 mM, calcium chloride 1 8 mM and sodium bicarbonate 0 5 mM) for about 5 min and then with a calcium-rich solution (sodium glutamate 58 5 mM, potassium glutamate 30 mM, calcium glutamate 20 mM and sodium bicarbonate 0 5 mM). The electrotonic potentials taken immediately before and approximately 30 sec after in the calcium-rich solution are shown in records *G* and *H*, respectively

These experimental results support the concept that the two stable states are the states in which the membrane calcium is either associated with or dissociated from the membrane[7] Presumably, the prolonged action potential is produced when the state of dissociation of the membrane calcium is sustained, and the hyperpolarizing response is produced when the association of membrane calcium takes place

Site of Action of Aldosterone on the Bladder of the Toad

The active transport of sodium by the urinary bladder of the toad, *Bufo marinus*, is increased when the animal[1] or the membrane itself[2–4] is treated with aldosterone Antidiuretic hormone also increases active sodium transport by the isolated toad bladder[5], this hormonal stimulation has been ascribed to a facilitated passive movement of sodium from the incubation solution on the mucosal side into the epithelial cells of the membrane[6], as a result, there is an increase of that fraction of tissue sodium concerned with the transfer of this ion across the preparation Hence the acceleration of the active extrusion of sodium, at the serosal border of the epithelial cells, can be taken as a mere consequence of an increased concentration of substrate—namely sodium—made available to the 'pump

An experimental approach among those devised by Frazier, Dempsey and Leaf[6] for the elucidation of the action of antidiuretic hormone on active sodium transport by the isolated toad bladder was adopted in order to obtain information concerning the site of action of aldosterone

Two subcutaneous injections of 50 μg *dl*-aldosterone-21-acetate, dissolved in 0 05 ml ethanol diluted to 0 25 ml with frog Ringer solution, were administered to toads, *Bufo marinus*, 16 and 4 h before death After pithing, both bladder halves of each toad were dissected and mounted between conical 'Lucite' chambers (inner diam 20 mm) according to Ussing and Zerahn[7] In a first series of experiments, incubation was carried out in frog Ringer fluid in which sodium was replaced by choline After 15 min part of this sodium-free solution on the mucosal side was removed and frog Ringer fluid containing tracer amounts of sodium-22 was introduced on that side The membranes were maintained short-circuited for 90 min, measured samples of incubation fluid on either side of the preparation were collected immediately before removal of the tissue which was blotted, care being taken not to contaminate one surface with the solution on the other side Bladder tissue was weighed in tared tubes before and after drying overnight at 95° C Radioactivity in the tissue and the incubation fluid was determined, and the amount of sodium-22 per unit tissue water was expressed as a function of the concentration of this radioisotope on the mucosal side The final concentration of sodium in the solution on that side was measured by flame photometry The pertinent results are given in Table 1, each value is the average of 4 determinations Mean short-circuit current and tissue labelling with sodium-22 were increased when the toads had been treated with aldosterone, mostly at the higher concentration of sodium used

Table 1 Influence of Aldosterone on Active Sodium Transport by the Isolated Toad Bladder and on Tissue Labelling with Sodium-22

	Membranes from untreated toads		Membranes from toads treated with aldosterone	
(1) Serosal surface exposed to choline–Ringer fluid				
Concentration of sodium on mucosal side (mM /l)	15 1	40 8	14 5	41 5

Tissue labelling† (% ± *S E*)	18 72 ± 4 42	10 98 ± 2 22	22 84 ± 3 82	18 46 ± 2 94
(2) Serosal surface exposed to sodium–Ringer fluid				
Concentration of sodium on mucosal side (mM /l)	10 0	40 0	10 0	40 0
Short-circuit current* (μamp)	33	47	91	106
Tissue labelling† (% ± *S E*)	7 57 ± 0 25	6 00 ± 0 53	20 00 ± 4 94	21 88 ± 6 49

* Average value of the last 30-min periods of incubation
† Concentration of sodium-22 in tissue water relative to that on the mucosal side

In view of the modesty of the short-circuit current—a quantitative expression of net sodium transport, even under such experimental conditions[6]—a similar number of investigations was performed on membranes the serosal surface of which was exposed this time to the usual frog Ringer solution, containing sodium, furthermore, incubation was interrupted after 45 min, which period of time is still amply sufficient for equilibrium to be reached between the 'active sodium transport pool' of the preparation and the solution on the mucosal side[6,8] In these circumstances, the behaviour of the untreated membranes was more satisfactory, the marked increase of sodium transport as well as that of bladder tissue labelling as a result of aldosterone treatment are thereby rendered more meaningful (Table 1)

Although quite different in their characteristics, the effects of antidiuretic hormone and aldosterone on active sodium transport by the isolated toad bladder are additive[1,2] The influence of this hormonal combination was therefore examined with regard to the size of the tissue sodium pool concerned with the active transport of this ion Experiments were carried out on paired bladder halves, one of which incubated as just described while the matched membrane was exposed simultaneously to 125 mU/ml vasopressin ('Pitressin', Parke, Davis and Co) It appears from Table 2 that antidiuretic hormone regularly increased active sodium transport and tissue water labelling with sodium-22, as has been reported by Frazier *et al* [6], this occurred even when the membranes were under the stimulating influence of aldosterone

These results thus are compatible with the interpretation that aldosterone stimulates the active transport of sodium by the epithelial cells of the toad bladder at least in part because this hormone exerts on the mucosal border of these cells an influence such that the amount of sodium delivered to the 'pump' is increased Indeed, the amount of sodium drawn into the tissue from the mucosal side was found to be increased at the time of an accelerated

* Mean short-circuit current during the last 30-min period

† Concentration of sodium-22 in tissue water relative to that on the mucosal side of the membrane The total concentration of sodium on that side was 25 mM /l for this series of incubations

rate of transfer of sodium across the epithelial cell layer In this respect, the influence of aldosterone resembles that of antidiuretic hormone, and both hormones actually combine their effects on this presumably passive albeit carrier-dependent[8] transfer of sodium across the cell mucosal border How aldosterone facilitates this transfer and whether it acts in addition on the 'pump' directly are still unanswered questions

This work was supported by the Fonds de la Recherche Scientifique Médicale Belge (grant No 344) Aldosterone was kindly provided by Ciba, Basle, Switzerland, and 'Pitressin' by Parke, Davis and Co , Bornem, Belgium

Mesial Surface of the Brain and Genital Function

WORK on the mesial surface of the cortex has produced conflicting observations on the part played by the cingulate gyrus in behaviour Smith[1,2], Ward[3] and Glees *et al* [4] reported that cingulectomy produces profound changes in the social and emotional behaviour of monkeys and similar observations have been made by Kennard[5] on the cat In contrast, Pribram and Fulton[6] and Mirsky *et al* [7] have observed little or no permanent effect following bilateral ablation in the monkey and this conclusion has been supported by investigations on the cat[8]

Our observations have been restricted to sexual behaviour Adult rhesus monkeys (*Macaca mulatta*), two males and two females, were used in the investigation and were observed over a period of eighteen months They were caged individually and their sexual activity was assessed by caging the mating pairs together for half an hour each day for thirty consecutive days In the pre-operative control phase copulation occurred daily for the period of the assessment in each pair and was unaffected by the female cycle

Cingulectomy (areas 23 and 24) was performed through a fronto-parietal craniotomy The dura was reflected toward the midline and the gyrus was approached by retraction at the sensory cortex The ablations extended to the sensory cortex of the mesial surface, particularly in the second animal

In the first male the operation was carried out in two stages No impairment of locomotion was produced by the right-sided ablation but an inability to grip with the right hind-limb followed the left-sided craniotomy The sexual activity of the animal was assessed from the third post-operative day of each operation Copulation occurred daily for a period of thirty days in each case, although the animal had some difficulty in maintaining the position due to the impairment of grip Bilateral carotid angiography was normal The female gave birth to a normal healthy monkey twenty-nine weeks after the first stage and eighteen weeks after the second stage Copulation continued to within twelve weeks of the delivery

In the second male the ablation was carried out in a single stage, a total paraplegia was produced The female was caged regularly with the male from the third post-operative day During the stage of total paraplegia erection was not impaired, but as the animal was unable to adopt the copulatory position ejaculation did not occur With some recovery in the paralysis, daily copulation occurred and was maintained for a period of thirty days even though a considerable motor deficit was present

These investigations suggest that the cingulate gyrus is not essential for sexual performance in the monkey and would support the observation of Pribram *et al* [6,7] that the gyrus is not intimately concerned in emotional behaviour The paralyses of the hind limbs, produced by the lesions extending to the somatic area 1, were accompanied by normal sexual activity This observation would be in accord with the conclusions of MacLean and his associates[9–11] from work on the squirrel monkey (*Saimiri sciureus*), that the somatic and autonomic aspects of genital function may be integrated by subcortical systems.

Uptake of Tritiated Aldosterone by Rat Tissues

As Tait *et al* [1] have pointed out, the half-life of aldosterone in plasma does not reflect metabolism alone The calculated 'volumes of distribution' for the body compartments exceed that of total body water, suggesting that aldosterone is selectively taken up by some region of the body[2] The work recorded here shows that injected tritiated aldosterone is unevenly distributed in the various tissues, that the rate of its disappearance from the tissues varies, and that in the liver the radioactivity is found predominantly in the supernatant fraction

Male Holtzman rats, 275–300 g, maintained on a synthetic diet with a constant daily intake of sodium and potassium were used throughout Four microcuries of chromatographically pure 1,2-^{3}H-*d*-aldosterone (100 mc / mg) in 2 ml. of 5 per cent glucose were injected into the tail vein Groups of rats, consisting of four animals, were killed by decapitation at intervals after injection of 5, 15, 30, 60 and 90 min A sample of blood was collected The tissues (heart, lung, muscle, spleen, intestine, aorta, brain, adipose tissue, kidney and liver) were immediately removed, dropped into ice-cold 0 25 M sucrose and allowed to chill. They were then blotted, weighed, finely minced, and homogenized in 2 5 ml of 0 25 M sucrose/g tissue Blood was hæmolysed by allowing it to stand with ten times its volume of cold de-ionized water A portion of each homogenate was extracted with 7 5 volumes of dichloromethane The various extracts were analysed for aldosterone by a slight modification, as described by Ayers *et al* [2], of the double isotope derivative assay

The total dichloromethane-soluble radioactivity of each tissue was determined by extracting 3 ml of the homogenate with 7 5 volumes of dichloromethane, drying the extract with a stream of air, transferring the material to counting vials, adding 5 ml phosphor, and counting in a liquid scintillation spectrometer Suppression of counts by the chromogens in the tissues was corrected by adding a known amount of tritiated toluene to each sample, recounting, and determining recovery When a known amount of tritiated aldosterone was added to unlabelled homogenates and analysed by the foregoing procedure, 98 per cent of the added radioactivity was recovered

To determine the intracellular distribution of injected aldosterone in the liver, 20 μc of tritiated aldosterone in 2 ml of 5 per cent sucrose were injected into the tail veins of rats fasted overnight Fifteen min after injection, the rats were killed by decapitation The livers were perfused *in situ* with cold 0 9 per cent saline, immediately removed, and the subcellular components isolated by ultracentrifugation in a Spinco model *L* preparative ultracentrifuge according to the method recommended by Hogeboom[3] Nuclei were isolated by the method of Chauveau[4]

The histological distribution of radioactivity was shown in these rats by autoradiography Sections of brain, heart, aorta, duodenum, spleen, liver, kidney, skeletal muscle and skin were quick frozen using acetone plus dry ice With a cryostat at –20° C, sections 8μ thick were cut, mounted on slides, and dried The stripping film technique of Fitzgerald *et al* [5], using Kodak '*AR* 10 film', was followed to film the slides The slides were then sealed in dark boxes containing calcium chloride and kept at 5° for 21 days The film was developed in *D*19 developer (Eastman Kodak) for 7 min at 18° and fixed in acid fixer After washing in running tap water for 10 min, sections were stained with Harris hæmatoxylin Only areas showing a grain density much above background were considered indicative of the presence of radioactive material

The average results on the disappearance of dichloromethane soluble radioactivity from rat tissues are shown in Table 1 Five minutes after injection of tritiated aldosterone, radioactivity was more concentrated in the kidneys, heart and lungs than in blood Fifteen min after injection, all tissues investigated with the exception of brain and adipose tissue had a higher concentration of radioactivity than blood

Tritiated aldosterone plus its dichloromethane-soluble metabolites disappeared logarithmically with time for 60 min from blood, kidney, heart and muscle After an initial uptake period of 15 min, they also disappeared logarithmically from spleen, lung, aorta and brain The uptake of radioactivity by the adipose tissue was slower than by the other tissues The maximum concentration in this tissue was 30 min after injection The level of radioactivity in the small intestine, although as high initially as most of the other tissues, did not decrease over the first 60 min

The distribution and disappearance of tritiated aldosterone were determined in blood, kidney, heart, lung, duodenum, brain and liver They were shown to be closely related to the distribution and disappearance of dichloromethane extractable radioactivity in all tissues investigated other than the liver In other words, most of the lipid-soluble radioactivity was present as tritiated aldosterone rather than its metabolites

By preparative ultracentrifugation of liver homogenates obtained from four rats 15 min after injection of 20 μc tritiated aldosterone, 70 per cent of the dichloromethane-soluble radioactivity present was shown to be in the supernatant fraction The nuclei, mitochondria, microsomes and cellular debris each contained approximately 7 per cent of the radioactivity in the total homogenate

Table 1 DICHLOROMETHANE EXTRACTABLE RADIOACTIVITY IN RAT TISSUES AFTER INJECTION OF TRITIATED ALDOSTERONE*

	Min after injection

Fat	160	228	446	102	372

* Results are expressed as the mean level of radioactivity in tissues from four animals in c p m /g tissue

Preliminary investigations of the histological distribution of radioactivity in the tissues using autoradiography indicate that aldosterone is localized in the tubular epithelial cells of the kidney, along the muscle fibres both in skeletal and cardiac muscle, in the alveolar walls of the lungs, and in the parenchymal cells of the liver

Although the role of aldosterone in the renal re-absorption of sodium has been examined most extensively, other investigations indicate that aldosterone is also involved in sodium and perhaps potassium transport in extrarenal tissues It lowers the sodium/potassium ratio in the saliva, sweat, and the secretions of the gastrointestinal tract of adrenalectomized animals[6]. Renkema *et al* [7] demonstrated that the intestine of cows is involved in the excretion and retention of ingested sodium Moll and Koczorek[8] found that administration of aldosterone resulted in an increased absorption of sodium by the duodenum This effect was inhibited by aldosterone antagonists These observations suggest that circulating aldosterone influences the transmucosal transport of sodium in the intestine Perhaps the maintenance of a high level of injected aldosterone by both the duodenum and the kidney 90 min after injection as compared with the other tissues is a reflexion of its role in sodium transport in these tissues

The slow rate of concentration or binding of aldosterone by fat as compared with the other tissues is interesting. Parra and Reddy[9] suggested that the mechanism by which fat accumulates cortisol is a solubility phenomenon rather than the essentially physical phenomenon of protein binding Our results also suggest that the mechanism by which fat accumulates aldosterone is different from that occurring in other tissues

The appearance of tritiated aldosterone in brain shows that the blood-brain barrier is, to some extent, permeable to aldosterone

PHARMACOLOGY

Vitamin B_6 as an Antidote against the Rodenticide 'Castrix' (2-Chloro-4-methyl-6-dimethylaminopyrimidin)

THE 'Castrix' molecule (2-chloro-4-methyl-6-dimethylaminopyrimidin)[1,2] resembles the vitamin B_6-antagonist toxopyrimidin. In rodents poisoned with this rodenticide the symptoms are an initial depression followed in 40–60 min by a 'search and flight reaction', spasticity, and tonic-clonic seizures, often with tongue-bite. Sound and touch aggravate the severity of the seizures, which may end with death from respiratory failure, dependent on dosage. Survival for more than 5 h usually results in total recovery within 24 h. As these symptoms are almost identical with those seen after administration of certain carbonyl trapping agents and vitamin B_6-antagonists[3-6] we tried vitamin B_6 as an antidote.

A total of 540 mice were used for the experiments. In the strain of mice utilized the LD_{50} of 'Castrix' when administered subcutaneously was 1.3 mg/kg in males and 1.1 mg/kg in females. On oral administration the LD_{50} was 1.2 mg/kg in female mice.

In all experiments pyridoxin, pyridoxal or pyridoxal phosphate was administered subcutaneously in a dosage of 25 mg/kg, which dosage was chosen arbitrarily. Mice injected subcutaneously with twice the LD_{50} of 'Castrix' showed no symptoms when pyridoxin was injected simultaneously with the 'Castrix', while untreated controls showed almost 100 per cent mortality. In another experimental series 'Castrix' was injected intraperitoneally at a dosage of 2.5 mg/kg. The first muscular symptoms, spastic gait and raised tails, appeared in about 30 min, at which time half the animals were treated with pyridoxin. Among the treated animals no seizures were seen, and all symptoms of toxicity disappeared within 10 min. All mice in the control group died within 90 min. Pyridoxal and pyridoxal phosphate were found to have the same effect as pyridoxin, while thiamine, nicotinamide, riboflavin, glutamic acid, and pyruvic acid had no effect. The last two compounds were tested both separately and in combination.

As a further test of the antidotal effect, the LD_{50} was determined in 125 female mice pretreated with pyridoxal immediately before the intraperitoneal injection of 'Castrix'. In these circumstances the LD_{50} was found to be 137 mg/kg. At this high dosage no epileptiform seizures were seen. The only symptoms were somnolence, prostration, and a slight opisthotonus preceding death.

Amphotericin *B* in the Chemotherapy of Experimental *Schistosomiasis mansoni* in Swiss Mice

IN May 1963, Gordon, St. John and Olsen[1] reported the prolongation of life in Swiss mice experimentally infected with a Puerto Rican strain of *Schistosoma mansoni*, when treated for 5 days with 'Fungizone' (amphotericin *B* made soluble with deoxycholate, E. R. Squibb). In the foregoing experiment, treatment began at a level of 0.5 mg of 'Fungizone'/kg body-weight of mouse a day. The dosage was increased in two daily increments of 0.5 mg/kg to a final level of 1.5 mg/kg a day, which was maintained for three days. Treatment began twelve weeks after infection (approximately 6 weeks after the parasite had begun producing ova). By one week subsequent to the termination of treatment, 80 per cent of the untreated but only 27 per cent of the treated animals had died. A χ^2 test showed that the experimental results fit to a confidence limit of 98 per cent the hypothesis that treatment influenced survival.

The work described here was undertaken to demonstrate whether the observed prolongation of life was due to a reduction in the number of worm pairs per mouse (that is, a reduction of infection-level due to treatment with 'Fungizone').

The mice used in this experiment were strain *CD*–1 Swiss, obtained from Charles River Breeding Laboratories, Inc. The snails used to obtain cercariæ were laboratory-reared *Australorbis glabratus*, obtained from several sources. Both the snails and the parasites were of Puerto Rican origin.

Large numbers of snails were induced to shed cercariæ by placing them in artificial pond water, in a shallow 'Pyrex' baking pan, and exposing them to a fluorescent lamp at close range. By this method, a concentration of 100 cercariæ/ml. was obtained.

Mice were infected by intraperitoneal injection of 1 c.c. of the above-described cercariæ-water per mouse. Treatment with 'Fungizone' began 13 days after infection. Treated animals comprised four groups, receiving daily doses of 1.0, 1.5, 2.0, and 2.5 mg of 'Fungizone'/kg mouse for 40 days. A fifth group received no treatment of any kind subsequent to infection. Treatment in all groups began at the 0.5-mg/kg level and increased in daily increments of 0.5 mg/kg until the final levels were reached. For the first seven days, all treatment was intravenous, thereafter intraperitoneal. The animals were killed within five days after terminating the treatments. The individual infection-levels of all animals were determined by counting the number of viable worms per mouse. The worms in the mesenteric venules were counted by carefully searching these structures at a magnification of ten times with a dissecting microscope. Those which remained in the liver were counted by crushing this organ flat between two glass plates and carefully searching at a magnification of 10 times. No parasites were found associated with any other organ or system of the mice.

Statistical methods by which treatment groups were compared included a one-way analysis of variance for unequal sample sizes, and a calculation of the value of Student's *t* for each treatment group compared with the group that received no treatment.

Table 1 presents the treatment groups and the mean number of worms per group (that is, mean infection-level per group) with the standard deviation of each group mean.

Table 1

Group No.	Daily dosage 'Fungizone'	No. mice in group	Mean level infection	Standard deviation
A	none	11	32.7	16.9
B	1.0 mg/kg	12	30.8	20.2
C	1.5 mg/kg	19	18.9	11.4
D	2.0 mg/kg	9	18.1	9.7
E	2.5 mg/kg	10	14.6	6.4

An analysis of variance comparing the infection-levels for all groups is presented in Table 2.

Table 2

Source of variation	Degrees of freedom	Sum of squares	Mean square (variance estimate)
Between samples	(5—1)=4	(*SSB*) 3,025.74	$MSB=\frac{SSB}{4}=756.435$
Error	(61—5)=56	(*SSE*) 10,305.67	$MSE=\frac{SSE}{56}=184.048$
Total	(61—1)=60	13,331.41	

$$F=\frac{MSB}{MSE}=\frac{756.435}{184.048}=4.01$$

With the numerator at 4 degrees of freedom and the denominator at 56 degrees of freedom, at the 99 per cent confidence-level, $F \simeq 3{\cdot}7$. Therefore, variance due to treatment is significantly greater than the individual variance within each group.

In order to demonstrate which groups are responsible for the observed group variance, values of Student's *t* comparing the mean infection-level of each group with that of the untreated group were computed and are presented in Table 3.

Table 3

Group No.	Student's *t*	Confidence limits (%)
A	—	—
B	0·24	(10–20)
C	2·68	(98–99)
D	2·29	(95–98)
E	3·18	(99·0–99·9)

From the foregoing analysis of variance and computation of Student's *t* the following inferences can be drawn: (1) treatment with 'Fungizone' effectively lowers the level of infection of treated animals below the infection level of untreated animals; (2) 1·5–2·5 mg/kg administered in a daily series of 40 injections represents an effective range of therapy; (3) no significant effect was observed using 1·0 mg/kg a day for 40 days.

The reduction of the mean number of worms per mouse (mean infection-level) in mice treated with 1·5–2·5 mg/kg 'Fungizone' a day undoubtedly explains the earlier observations by Gordon, St. John and Olsen that treatment with 'Fungizone' significantly prolongs the life of infected animals.

The two types of observations suggest to us that amphotericin *B* is an effective agent in the chemotherapy of experimental *Schistosomiasis mansoni* in the Swiss mouse.

Since the agent has been pharmacologically characterized in man in the treatment of disseminated mycoses, we suggest its use in clinical trials to determine its effectiveness in the treatment of human schistosomiasis.

Action of Puffer Fish Poison

Puffer fish (Tetraodontoidea) is an important cause of food poisoning in China and Japan[1,2]. Murtha *et al.*[2] claimed that the poison acts centrally and peripherally to produce respiratory and neuromuscular paralyses. They offered as proof of its central action the more rapid onset of respiratory depression when the toxic extract was injected into the carotid artery than when it was injected intravenously. This is disputable because the carotid artery normally supplies blood to the cerebrum while the brain stem is supplied by the basilar artery[3]. Secondly, the peripheral neuromuscular paralysis as described by Murtha *et al.*[2] appears to be a late effect because the transmission in the phrenic nerve diaphragm preparation in their experiment was not blocked until 20–30 min after artificial respiration was resorted to for the respiratory arrest.

In the present investigation the crude extract of liver and gonads of puffer fish, prepared as described by Hashimoto and Migita[4], was separated chromatographically into three fractions. The fraction with the highest R_F was found to increase the contractility of isolated rabbit gut preparation, and the fraction with the lowest R_F inhibited this action. The middle fraction with R_F about 0·26 was proved to be the toxic fraction when injected into animals. In mice, the intraperitoneal *MLD* of the toxic fraction was $3{\cdot}08 \pm 0{\cdot}06$ μg/100 g body-weight, as computed from the probit-log dose relationship.

A progressive arterial hypotension is a constant feature in rats given the toxic fraction irrespective of the dosage. This was also found in dogs and cats after administration of extract of puffer fish[2]. In the rat administration of a small sub-lethal dose produced hypotension only, without respiratory or other apparent changes; therefore, it seems that this is an independent action. Preliminary investigation showed that cardiac output as measured with a cardiometer was unaffected, which suggests that hypotension is attributable to direct action of the puffer fish toxin on peripheral blood vessels. Further lowering of diastolic pressure when the toxic fraction was given after injection of a ganglion blocking agent (tetraethylammonium bromide) supports the foregoing hypothesis. The administration of antihistamine (diphenhydromine) before injection of a sub-lethal dose of toxic fraction prevented the fall in blood pressure, therefore, the hypotension may probably be due to the histaminic action of the puffer fish toxin. The hypotension is unlikely to be due to autonomic effect because the pressure response to carotid occlusion or adrenaline was not affected by administration of the toxic fraction, and atropine did not influence the hypotensive effect. Infusion of noradrenaline following injection of toxic fraction maintained the arterial blood pressure at normal level for about 1 h.

Large sub-lethal or lethal dose of toxic fraction caused respiratory depression in addition to hypotension. When the lethal dose was large, the respiration stopped when the fall in blood pressure was still slight. The respiratory arrest occurred more rapidly when the toxic fraction was injected into the subclavian artery (retrogradely via the carotid artery) than when the same dose was injected into the carotid artery or a vein. When Evans blue was injected into the subclavian artery of a rat the dye stained the brain stem only, while injection of the dye into the carotid artery stained the cerebrum only. Therefore, the rat brain stem was supplied, as in other animals[3], with blood from the basilar artery. Thus, the cause of death following a lethal dose of the toxic fraction appears to be respiratory arrest from central action of the toxin on the brain stem respiratory centres. The view is supported by the finding that intracisternal injection of the toxic fraction, in a dose which was non-lethal when given intraperitoneally, caused immediate cessation of respiration.

HÆMATOLOGY

A Hæmagglutination Phenomenon between Tanned Erythrocytes and Sera of Guinea Pigs

In the course of experiments designed to examine the effect of serum on the streptolysin-*S* susceptibility of tanned erythrocytes[1], guinea pig erythrocytes treated with tannic acid in the cold were suspended in 1 : 100 dilution of fresh serum from tuberculous guinea pig. A heavy hæmagglutination appeared a few minutes after mixing. No such heavy agglutination was observed either with

The figures are the final readings taken 25 min after mixing the cells and the serum. The hæmagglutination was graded by noting the gross amounts of settled cells on the bottom of the tube ; —, negative ; ±, clumpings with little or no settlings ; + + + +, almost complete settlings ; +, + + and + + +, intermediate settlings.

heat-inactivated tuberculous serum or with fresh serum of normal animals. These observations led us to further investigations on this curious hæmagglutination phenomenon, provisionally designated as 'tanned erythrocyte (TE-)agglutination' to differentiate it from the Boyden's antigen–antibody hæmagglutination[2].

Erythrocytes from normal healthy guinea pigs, weighing 400–700 g, were used. Blood was collected by heart puncture in 1·2 vol. of modified Alsever's solution and centrifuged. The packed red cells were washed 4 times in phosphate-buffered saline (*p*H 7·2) consisting of 10 vols. of 0·85 per cent saline and 1 vol. of 0·1 M phosphate buffer. The washed cells were finally suspended in buffered saline to the original volume. The preparation of tannic acid-treated erythrocytes was carried out in a cold room (2° ± 2° C). Two ml. of the washed erythrocyte suspension were added to 40 ml. of 1 : 10,000 tannic acid (J.P.) diluted in buffered saline. The mixture was left for 30 min in the cold, then centrifuged, the cells washed 3 times in buffered saline, and finally re-suspended to the original volume. Guinea pig sera were recovered after clotting blood samples at room temperature. The tuberculous sera used were obtained from guinea pigs infected, at least one month beforehand, with 0·2–0·5 mg (semi-moist weight) of a human tubercle bacillus *H37Rv* grown on Sauton's medium. Dilution of serum was made in buffered saline. For agglutination test centrifuge tubes (12 mm × 100 mm) were used. To the tube containing 4 ml. of a dilution of test serum was added 0·2 ml. of tanned erythrocyte suspension. The tube, after agitation, was placed at room temperature, and the readings made at 5-min intervals.

As shown in Fig. 1, agglutination of tanned erythrocytes by tuberculous serum occurred, within 5–15 min after mixing the cells and the serum, as coarse clumpings which soon aggregated into gross masses and then settled down on the bottom of the tube. The reaction reached its end-point within 30 min. As shown in Table 1, the titrations of sera from tuberculous and normal guinea pigs for their TE-agglutinating capacity revealed that there were considerable differences between the individual serum specimens in the appearance of agglutination in relation to serum dilutions. Tuberculous serum No. 1 gave a titre of 1 : 512, and the occurrence of the agglutination increased with increase of the serum concentrations. Tuberculous serum No. 2 gave more or less definite agglutination in all dilutions ranging from 1 : 2 to 1 : 256, the grades of which were, however, quite irregular with respect to the serum concentrations.

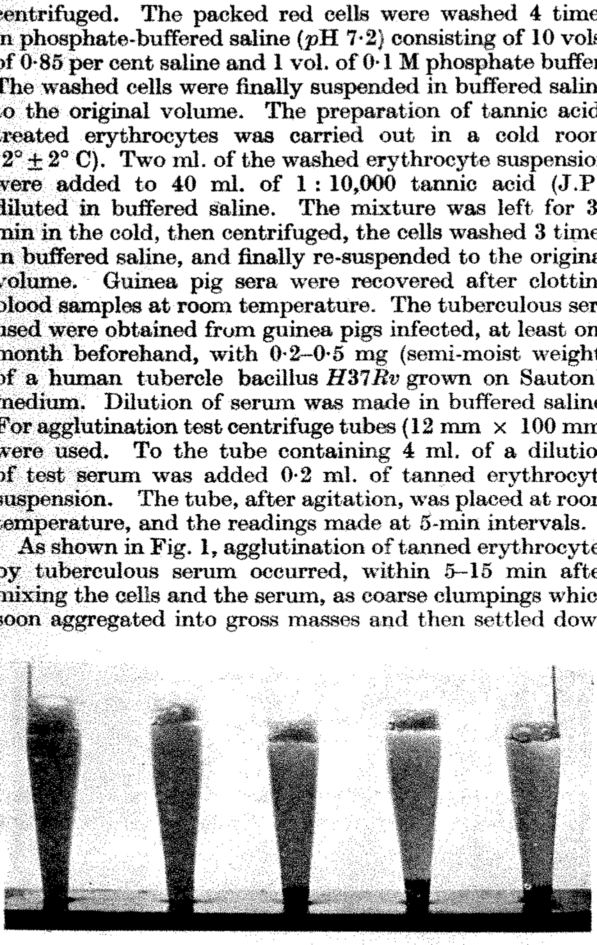

Fig. 1. Time-course of tanned erythrocyte agglutination by tuberculous guinea pig serum (1 : 100). Left to right : after 5, 10, 15, 20 and 25 min

Other sera showed no agglutination up to dilution of 1 : 16 or 1 : 32 (inhibiting prozone), and only when further diluted beyond this point they caused varying degrees of agglutination. It is worthy of note that the positive sera of the last group showed the maximum agglutination at dilutions of 1 : 64 to 1 : 128. It is interesting to note that the capacity of the most normal sera to produce the hæmagglutination was much weaker, as compared with that of the tuberculous sera. Further experiments carried out with tuberculous sera revealed that the TE-agglutination was dependent on a number of variables : when the tanned red cells of guinea pig were replaced with the cells of sheep, goat, ox, rabbit, rat, mouse or chicken, no hæmagglutination occurred, while those of horse, pig, man or cat were more or less sensitive to the agglutination. Tanning of red cells should be carefully carried out in the cold (0°–5° C), and no consistent results were obtained with the erythrocytes tanned at higher temperatures. The TE-agglutinating activity of the serum was completely annulled by heating it at 56° C for 30 min, and the lost activity of the heated serum was not restored by the addition of fresh serum of normal animals. The activity was non-dialysable and not affected by pretreatment with weak ammonia or zymosan.

These results suggest that complement[3,4] is not involved here. Electrophoresis investigations indicated that the TE-agglutinating activity of the guinea pig serum is present in γ-globulin fraction. In addition, it was found that the 'inhibiting prozone' demonstrated in the titration tests could be easily removed by a single, careful pretreatment of the serum with tanned erythrocytes, resulting in a marked enhancement or an unmasking of the serum capacity to produce the TE-agglutination. From all these results it was supposed that there are at least two factors in guinea pig serum, one of which is capable of agglutinating tanned erythrocytes, that is, agglutinator, the other being capable of inhibiting the agglutination, that is, inhibitor, and we are at present of the opinion that a strongly positive TE-agglutination test, as was observed on the tuberculous guinea pigs in this investigation, may be an indication of a disturbed state of serum in its 'agglutinator-inhibitor' relation.

HISTOLOGY

A Unique Pattern of Localization within the Cerebellum

IT has been generally accepted that the microscopic structures of the individual layers of the cerebellum are invariant in all animals. For example, Kappers *et al.*[1] state that "different cytoarchitectonic regions, such as are demonstrable in the various areas of the cerebral cortex, are not present in the cortical portion of the cerebellum". This absence of localization of histological structure has been a hindrance to research in view of the known localization of function in different regions of the cerebellum.

During the course of certain experiments in this laboratory it was noted that there was a microscopically observable difference in the 'staining' intensity in the histochemical test for the enzyme 5′-nucleotidase between the anterior and posterior portions of the cerebellum in mice. This difference was found in the molecular layer (Fig. 1). Microdensitometry indicated a 2-fold difference in activity between the two portions. The enzyme was demonstrated by a modification of Naidoo's[2] method, using 10μ thick cold-microtome sections. In coronal section, on the other hand, the enzyme was seen to be distributed in a series of bands which ran in an antero-posterior direction (Fig. 2). These bands were wider posteriorly than anteriorly, thus accounting for the antero-posterior differences originally noted (Fig. 1).

This unique pattern was observed in mice of all ages from 11 days to 13 weeks but not of 4 or 7 days of age. There were no sex differences and no such distributional pattern was seen with any of 16 other enzymes examined.

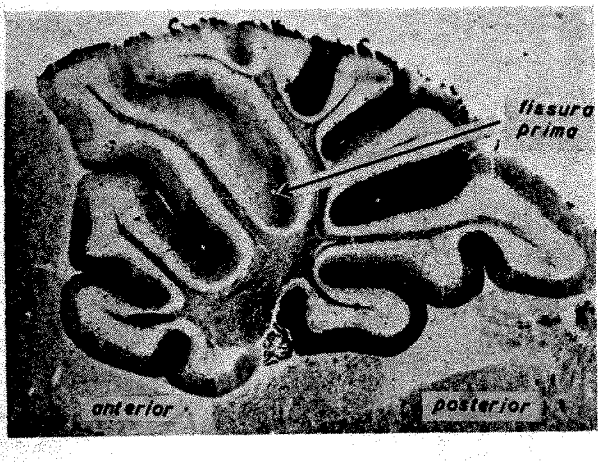

Fig. 1. Paramedian section of cerebellum of 8-week-old mouse showing 5-nucleotidase activity (no counter stain). (× *c.* 15)

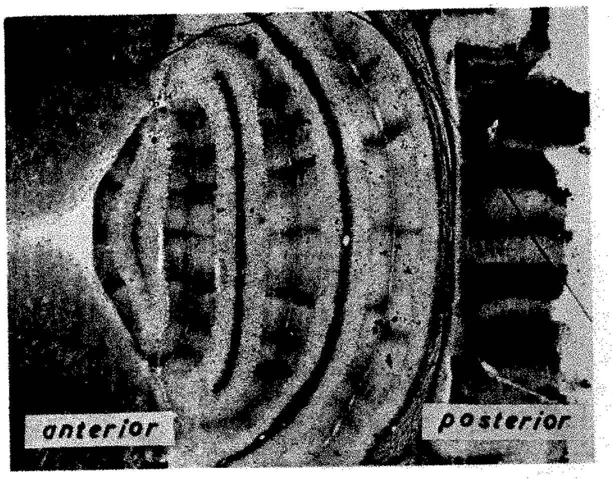

Fig. 2. Coronal section (slightly oblique) of cerebellum of 10-week-old mouse showing the banded distribution of the enzyme. (× *c.* 19)

The significance of this discovery is not immediately apparent. The transition between the two zones occurred at the apex of the folium immediately posterior to the fissura prima in all the mice examined. The increased enzyme activity of the zone is present right up to the posterior margin of this layer in the roof of the 4th ventricle. It therefore does not differentiate paleocortex from neocortex, and in consequence it must be supposed that it has little or no phylogenetic significance.

Ontogenetically it would suggest that the posterior wall of the fissura prima is to be included in the anatomically anterior portion of the cerebellum, and that any functional differences between anterior and posterior terminate not at the base of the fissura prima, as might be supposed, but caudal to it.

The significance of the antero-posterior banding is not known.

Histochemical Reaction for Steroid-3β-ol-dehydrogenase in the Interrenal and the Corpuscles of Stannius of *Anguilla anguilla* and *Conger conger*

SINCE Giacomini's[1] demonstration that the interrenal tissue of the 'head-kidney' in teleosts is embryologically and anatomically independent of the corpuscles of Stannius, doubt has remained as to the participation of these corpuscles in the production of corticosteroids.

Phillips and Mulrow[2] and Nandi and Bern[3] have given direct evidence for the secretion of these hormones by the interrenal tissue. Ford[4] did not manage to identify corticosteroids in extracts of corpuscles of Stannius in the pacific salmon, *Oncorhynchus nerka*, just as Phillips and Mulrow[5] had shown that *in vitro* cultures of the corpuscles of Stannius from *Pseudopleuronectes americanus*, incubated in the presence of tritiated progesterone, lack the capacity to synthesize adrenocorticosteroids. The latter results show indirectly that the enzymes responsible for steroidogenesis are absent from the corpuscles of Stannius.

In order to obtain direct proof of the absence of steroidogenesis in this gland, we have carried out a histo-

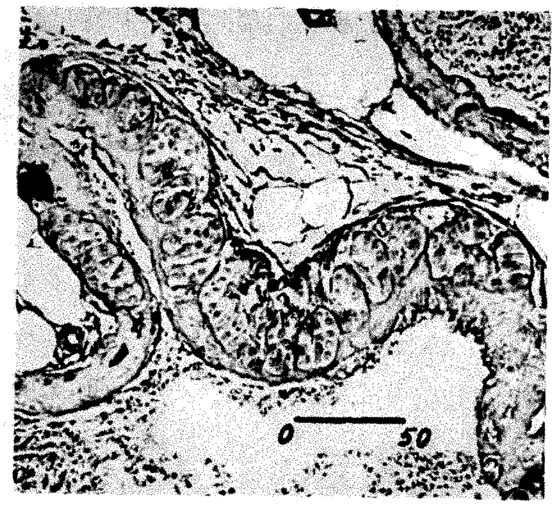

Fig. 1. Cross-section of the 'head-kidney' of *Anguilla anguilla*. The cords of interrenal cells are scattered in the wall of the blood vessels (hæmatoxylin and eosin)

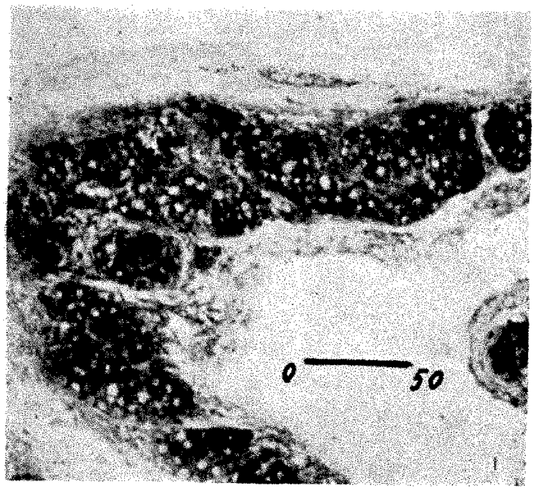

Fig. 2. Cross-section of the 'head-kidney' of *Anguilla anguilla*. Positive reaction for steroid-3β-ol-dehydrogenase in the interrenal cells: note the precipitation of granules of formazans

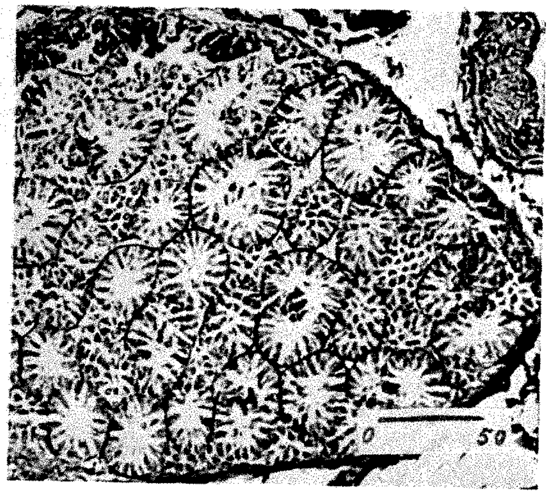

Fig. 3. Cross-section of the corpuscle of Stannius of *Anguilla anguilla* (hæmatoxylin and eosin)

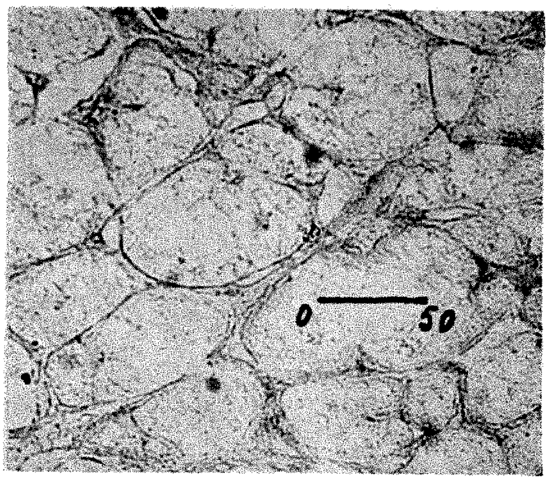

Fig. 4. Cross-section of the corpuscle of Stannius of *Anguilla anguilla*. Reaction for steroid-3β-ol-dehydrogenase: note the absence of the granular precipitation of formazans. Counterstaining with carmalum

chemical reaction for steroid-3β-ol-dehydrogenase, both on the interrenal tissue and on the corpuscles of Stannius from *Anguilla anguilla* and *Conger conger*, following the technique of Wattemberg[6], modified by Levy *et al.*[7,8]. This enzyme, which is responsible for the transformation of pregnenolone into progesterone, has been shown to be present only in the steroid-secreting glands of vertebrates[6-11].

The interrenal tissue, which is found along the blood vessels of 'head-kidney', consists of cords of cubical or cylindrical cells, arranged in the form of alveoli (Fig. 1). The corpuscles of Stannius, which are found on the ventral or dorsal surface of the kidney, are formed of alveoli of cylindrical cells, with very characteristic spaces in the middle (Fig. 3). The reaction for steroid-3β-ol-dehydrogenase was positive only for the interrenal cells (Fig. 2), but was constantly negative in the corpuscles of Stannius (Fig. 4).

The specificity in the location of this reaction has been further emphasized by the ubiquitous histochemical distribution of the lactic-dehydrogenase, which, like the other enzyme, is DPN-dependent.

Therefore it can be concluded that, while the function of a gland of steroid secretion is confirmed for the interrenal tissue, this function is definitely excluded for the corpuscles of Stannius in *Anguilla anguilla* and *Conger conger*.

This investigation was supported by a research grant *RG*–6455 from the Division of General Medical Sciences, U.S. Public Health Service.

RADIOBIOLOGY

Determination of Radiation-induced Mutation Rates of Recessive Lethal Alleles in *Saccharomyces*

COMPARING X-ray inactivation curves of haploid and diploid strains of *Saccharomyces*, Latarjet and Ephrussi[1] were the first to suggest that radiation inactivation of yeast cells may be caused by an induction of recessive and dominant lethal mutations. The first evidence of X-ray-induced recessive and dominant lethal mutations was obtained by Mortimer[2] by means of tetrad analysis and specific mating experiments respectively. Recently the number of loci which may be induced by ultra-violet or X-rays to mutate to corresponding recessive lethal alleles as well as the average mutation rate of these loci has repeatedly been estimated after taking into consideration inactivation by dominant lethal mutations and other lethal effects[3,4]. Although the mean mutation rates determined in different laboratories do show a good correspondence, they are much higher than ultra-violet or X-ray-induced mutation rates from auxotrophic to prototrophic conditions or vice versa[4,5]. This striking difference in mutation rates demands a new independent investigation of the frequencies of radiation-induced recessive lethal mutations. If the estimated high mean mutation rates of recessive lethal mutations do correspond with reality, an investigation of specific mutation rates of a number of individual loci should reveal certain loci exhibiting high mutation rates.

An attempt to determine radiation-induced mutation rates of specific genes to recessive lethal alleles has been undertaken by comparing the survival rates of irradiated diploid cells heterozygous for one recessive lethal allele ($S_{+/l}$) with those of diploid cells homozygous for the corresponding vital alleles ($S_{+/+}$). The mutation rate t_m of a specific vital allele to a recessive lethal condition can be calculated using a general equation for cell inactivation[6]:

$$S_{+/+} = (1 - D) \; . \prod_{i=1}^{m} (1 - t_i^2) \qquad (1)$$

The survival rate of diploid cells heterozygous for one recessive lethal allele is given by:

$$S_{+/l} = (1 - D) \; . \prod_{i=1}^{m-1} (1 - t_i^2)(1 - t_m) \qquad (2)$$

In these equations D stands for the rate of inactivation by effects other than recessive lethal mutations and m for the number of loci per chromosome set which can mutate to a recessive lethal condition. It follows:

$$t_m = \frac{S_{+/+}}{S_{+/l}} - 1. \qquad (3)$$

Saccharomyces strains heterozygous for one recessive lethal mutation (+/l) were isolated from the diploid strain 241 of our strain collection after irradiation with small doses (≈ 90 per cent survivors) of X-ray or ultra-violet. Strain 241 is carrying no recessive lethal allele and therefore is of the genotype +/+. An induced heterozygosis for one recessive lethal mutation is recognizable by a 2 : 2 (colony-forming ability : non-colony-forming ability on complete medium) segregation of ascospores in tetrad analysis. At least 10 tetrads of every isolated strain were analysed. Only those strains the ascospores of which exclusively exhibited a 2 : 2 segregation were selected as heterozygotes for further inactivation experiments.

The accurate reproducibility of experimental results necessary for the determination of relatively small differences in survival rates could only be achieved in inactivation experiments with X-rays. The cultures were prepared according to the method described by Wood[7] with minor modifications being applied. In Table 1 the survival frequencies after irradiation with 85 krads X-ray are given for 3 X-ray-induced +/l-strains and the +/+-parental strain 241. The maximum mutation rate obtained was 0·25. The most sensitive +/l-strain, 241*x*-2, was chosen for an investigation of the dose dependence of t_m. From the dose effect curves given in Fig. 1, t_m-values were calculated, which show a linear increase with dose up to 85 krads (Fig. 2).

Table 1. SURVIVAL FREQUENCIES AND CALCULATED MUTATION-RATES OF FOUR *Saccharomyces* STRAINS AFTER IRRADIATION WITH 85 KRADS X-RAYS

Strain	Genotype	Frequency of survivors (%)	No. of independent determinations	Mutation-rate t_m (+ → l)
241	+/+	21·3 ± 0·5	15	—
241*x*-2	+/l	17·1 ± 0·4	16	0·25
241*x*-10	+/l	18·6 ± 1·0	3	0·15
241*x*-17	+/l	20·7 ± 1·2	3	(0·03)

Besides the 3 X-ray-induced +/l-strains there were also 5 ultra-violet-induced +/l-strains isolated, the X-ray-sensitivity of which was determined. None of these strains proved to be more X-ray-sensitive than the parental +/+-strain. Two of the ultra-violet-induced +/l-strains were also checked for their ultra-violet-sensitivity and compared with the ultra-violet-sensitivity of the parental +/+-strain. Although the results obtained in different ultra-violet experiments could not be reproduced very accurately the +/l-strains generally did show an increased ultra-violet-sensitivity. t_m-values, tentatively calculated, were of the same range as those given in Table 1 for X-ray experiments.

Since it is of interest to know also whether homozygous +/+-strains with a significantly increased X-ray sensitivity do occur, survival rates after irradiation with 85 krads X-rays of several sub-clones isolated from strain 241 were determined. The results obtained are in good agreement with those of the parental strain 241 (Table 2).

As may be seen in Table 1 two out of three investigated +/l-strains did show a significantly increased X-ray sensitivity as compared with the values obtained for the parental +/+-strain. Mutation rates of 0·15 and 0·25 were calculated from these data. The occurrence of

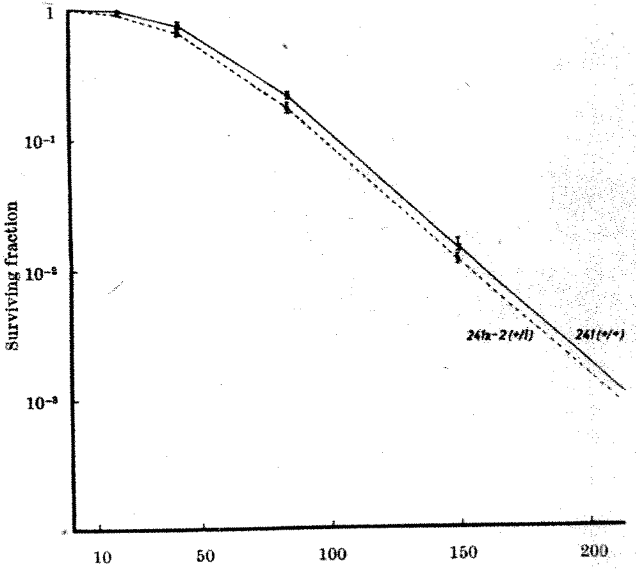

Fig. 1. X-ray inactivation curves for the diploid strain 241*x*-2 heterozygous for one recessive lethal allele (+/l) and for the parental strain 241 homozygous for the corresponding vital alleles (+/+). Vertical bars indicate the mean standard deviation. Irradiation source was a Machlett X-ray tube, operated at 50 kV, 9 m.amp, beryllium window without additional filter

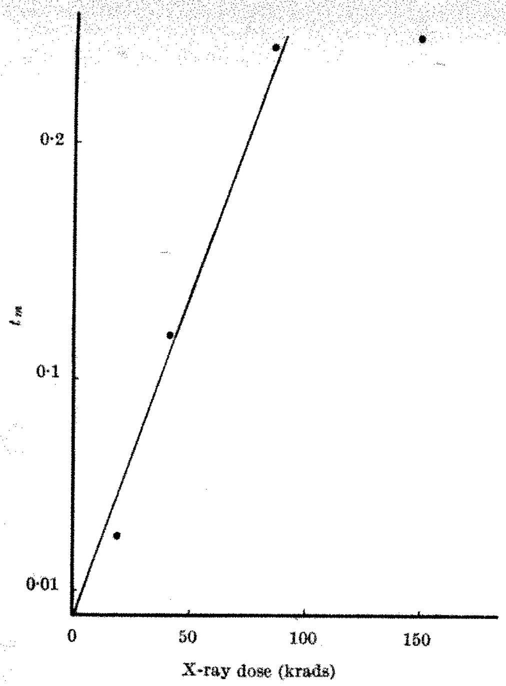

Fig. 2. X-ray dose dependence of t_m calculated from Fig. 1 with the help of equation (3)

extremely high mutation rates to recessive lethal alleles in *Saccharomyces* is thus confirmed. It must be taken into account, however, that the method used for obtaining heterozygous +/l-strains is highly selective for the isolation of mutants with high mutation rates. Therefore, one has to expect that besides the observed highly mutable groups of genes there are also others with definitely smaller mutation rates to recessive lethal conditions. Although radiation-induced recessive lethal mutations evidently do occur, definite evidence is still lacking that they play a major part in killing of haploid cells. About possible reasons for the observed high mutation rates only speculations are possible. They may be caused by radiation-induced inactivation of especially long critical chromosome regions.

Table 2. SURVIVAL FREQUENCIES OF SIX SUB-CLONES OF STRAIN 241 AFTER IRRADIATION WITH 85-KRADS X-RAYS

Resorption of Necrotic Lens Material by a Newly Formed Lens Capsule in Certain Types of Cataract

THE formation of a new lens capsule by regenerated epithelial cells under a superficial area of necrosis has been described by several authors. It may easily be observed by means of optical microscopy in some senile cataracts or in localized traumatic cataracts after periodic acid–Schiff staining.

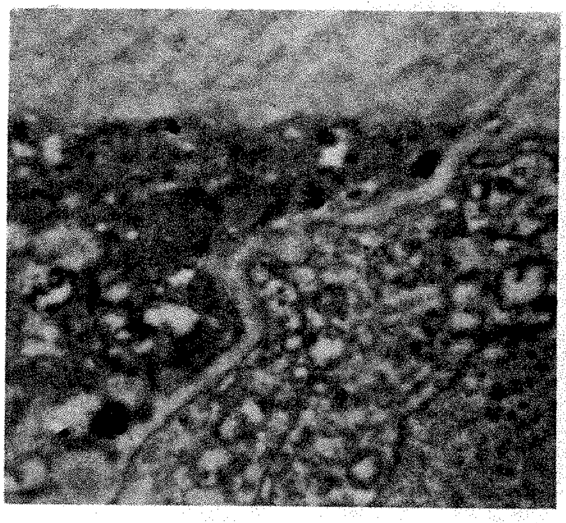

Fig. 1. Senile cataract. Under a normal capsule, a necrotic area (on left) is separated from the normal epithelium (on right) by a newly formed capsule which is in continuity with the normal capsule (right upper corner)

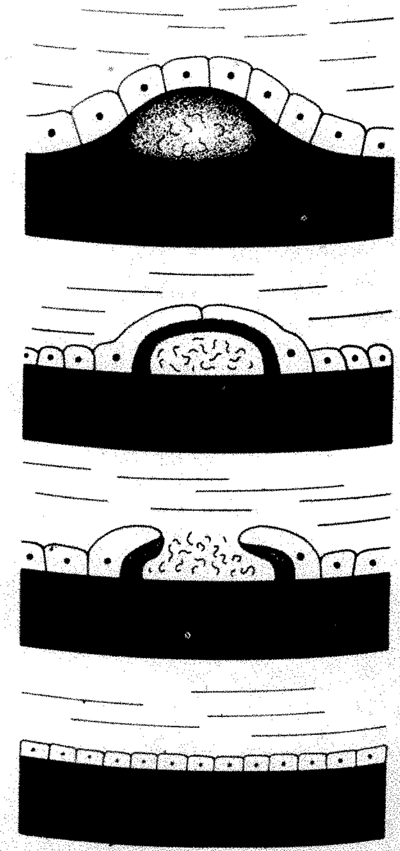

Fig. 2. Diagram showing the successive stages of the resorption of a small necrotic area inside the newly formed capsular material

Electron micrographs of senile cataracts[1] show the newly formed capsule between the normal epithelium and the necrotic area (Fig. 1). This newly formed capsule shows a definite tendency to grow more and more closely to the normal one, and finally to merge with it. Thus, the necrotic material is included in the capsular substance. The necrosis will disappear progressively. The end of this evolution is a localized area of a thickening of the capsule. The stages of this process are shown diagrammatically in Fig. 2.

We had the opportunity of observing the same features in experimental traumatic cataracts.

This seems to be the interesting point of these electron microscopic observations. It explains the well-known localized areas of the thickening of the capsule in cataracts, and the possible disappearance of some small superficial opacities of the lens.

Wounds and the Polarity of Implant-induced Accessory Urodele Limbs

Previous work[1-3] has established that xenoplastic implants made into the limbs of larval and adult urodeles would initiate the formation of accessory limb structures and, further[4], that the position of the superficial wound used for insertion of the implanted material seemed to have a very decided effect on the stimulus-response system. The implants would not take advantage of wounds made proximal to the implant so readily as they would of distal wounds. In larvæ, as well as adults, very few growths were produced from proximal wound areas. These few supernumerary limbs which did form in association with proximal wounds, however, showed interesting growth patterns which are better understood to-day than they were at the time of the previous writing.

The purpose of this communication is to supply newer information on the relationship between a superficial insertion wound and the formation and polarity of the resultant supernumerary limb and in particular to correlate these relationships with long-standing morphogenetic rules, Barfurth's rule[5] and Bateson's rule[5].

First, it should be noted that the wound relationships found previously apply if an implant of moderate size is placed in such a way as to be completely included beneath the skin cover without protruding through the open wound. If, however, larger quantities of implant material are used which are allowed to protrude through the open insertion wound, thereby delaying the wound healing phase, supernumerary limbs may be obtained in many instances regardless of the position of the wound. With this information, then, it became possible to study readily the polarity of implant-induced accessory limbs in association with wounds made in a variety of positions.

Thirty adult *Triturus viridescens* from Petersham, Massachusetts, were utilized as hosts, while the kidneys of a single adult male *Rana pipiens* from Oshkosh, Wisconsin, served as donor material. Six different experimental situations were established, using both forelimbs of each animal. These situations differed in the position of the insertion wounds, which were made proximal, distal, anterior or posterior to implants placed on the dorsal surface of the radio-ulnar portion of the forelimb; and proximal or distal to implants on the ventral surface of the limb. Our previous experience, as already noted, had shown that the position of the wound does play a hand in establishing the early growth pattern of the induced accessory limb.
